# Wireless Semiconductor Solutions

## RF and IF Device Data

---

### FOREWORD

This publication includes technical information for the several product families that comprise the Motorola portfolio of Wireless Semiconductor RF and IF Products. The product families include bipolar, LDMOS, MOSFET RF Power, and gallium arsenide chip technologies in a variety of ceramic and plastic surface mount packages. Discrete components, hybrid modules, and integrated circuits provide different levels of complexity in an effort to provide solutions for our customers' needs.

All devices are in alphanumeric order in the *Device Index* of this book. Just turn to the appropriate page for technical details of the known device. Complete device specifications are provided in the form of *Data Sheets* which are categorized by product type into six chapters for easy reference. *Selector Guides* by product family are provided at the beginning of the book as well as in the beginning of each chapter to enable quick

comparisons of performance characteristics and to aid you in identifying devices that meet your functional performance requirements of frequency, output power, gain, or other parameters.

Chapters on Tape and Reel Options, Packaging Information, Applications and Product Literature include additional information to aid you in the design process.

Applications assistance is only a phone call away — call the nearest Semiconductor Sales office or 1-800-521-6274. Please refer to our section on *On-line Access to Wireless Semiconductor Data* so that you will always have easy access to the most current information available on Motorola's Wireless Semiconductor product portfolio.

The information in this book has been carefully checked and is believed to be accurate; however, no responsibility is assumed for inaccuracies.

Motorola reserves the right to make changes without further notice to any products herein. Motorola makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Motorola assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters which may be provided in Motorola data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. Motorola does not convey any license under its patent rights nor the rights of others. Motorola products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Motorola product could create a situation where personal injury or death may occur. Should Buyer purchase or use Motorola products for any such unintended or unauthorized application, Buyer shall indemnify and hold Motorola and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Motorola was negligent regarding the design or manufacture of the part. Motorola and  are registered trademarks of Motorola, Inc. Motorola, Inc. is an Equal Opportunity/Affirmative Action Employer.

## ABOUT THIS REVISION

The Wireless Semiconductor Solutions RF and IF Device Data Book is contained in two volumes. This edition encompasses a considerable number of changes that have occurred since our last printing. Some devices have been removed from this book due to package changes or new technology replacements and many new devices have been added.

Application Notes, Engineering Bulletins and Article Reprints of special interest to designers of RF and IF equipment are available on the Motorola Semiconductor Product Sector Web site or are available through the Motorola Literature Distribution Center. Phone and fax numbers for ordering literature are listed on the back cover of this book and in our Accessing Data On-line section. See Chapter Ten for a complete listing of Application Literature.

For Cross Reference information on Motorola replacement devices, please consult your local Distributor or Motorola Sales Office. See Chapter Eleven in this data book for a complete listing of Motorola Distributor and Worldwide Sales Offices.

## DATA CLASSIFICATION

### Product Preview

This heading on a data sheet indicates that the device is in the formative stages or in design (under development). The disclaimer at the bottom of the first page reads: "This document contains information on a product under development. Motorola reserves the right to change or discontinue this product without notice."

### Advance Information

This heading on a data sheet indicates that the device is in sampling, pre-production, or first production stages. The disclaimer at the bottom of the first page reads: "This document contains information on a new product. Specifications and information herein are subject to change without notice."

### Fully Released

A fully released data sheet contains neither a classification heading nor a disclaimer at the bottom of the first page. This document contains information on a product in full production. Guaranteed limits will not be changed without written notice to your local Motorola Semiconductor Sales Office.

### Technical Summary

The Technical Summary is an abridged version of the complete device data sheet that contains the key technical information required to determine the correct device for a specific application. Complete device data sheets for these more complex devices are available from your Motorola Semiconductor Sales Office or authorized distributor.

## ACCESS MOTOROLA SEMICONDUCTOR TECHNICAL INFORMATION

### Access Data On-Line! – Use Motorola's SPS Internet Server

Motorola SPS has provided a World Wide Web Server to deliver Motorola SPS's technical data to the global Internet community. Technical data (such as data sheets, application notes, and selector guides) is available on the Internet server with full search capabilities. All have easy text search capability. Ordering literature from the Literature Center is available on line. Other features of Motorola SPS's Internet server include the availability of a searchable press release database, technical training information, with on-line registration capabilities, complete on-line access to the Mfax system for ordering faxes, an on-line technical support form to send technical questions and receive answers through email, information on product groups, full search capabilities of device models, a listing of authorized distributors, and links directly to other Motorola world wide web servers.

#### How to reach us:

After accessing the Internet, use the following URL:

<http://mot-sps.com/sps/>  
<http://mot-sps.com/rf/>  
<http://motorola.com/wireless-semi/>

#### How to reach MFAX directly on-line:

After accessing the Internet, use the following URL:  
<http://motorola.com/sps/mfax>

### Mfax™ - Touch-Tone Fax

Mfax offers access to over 30,000 Motorola documents for faxing to customers worldwide. With menus and voice instruction, customers can request the documents needed, using their own touch-tone telephones from any location, 7 days a week and 24 hours a day. A number of features are offered within the Mfax system, including product data sheets, application notes, engineering bulletins, article reprints, selector guides, Literature Order Forms, Technical Training Information, and HOT DOCS (4-digit code identifiers for currently referenced promotional or advertising material).

*A fax of complete, easy-to-use instructions can be obtained with a first-time phone call into the system, entering your FAX number and then, pressing 1.*

#### How to reach us:

**Email:** RMFAX0@email.sps.mot.com  
**Phone:** Motorola Fax Back System:  
TOUCHTONE 1-602-244-6609  
US & Canada ONLY 1-800-774-1848  
**Internet:** <http://sps.motorola.com/mfax/>

### Literature Centers

Printed literature can be obtained from the Literature Centers upon request. For those items that incur a cost, the U.S. Literature Center will accept Master Card and Visa.

#### How to reach us:

##### USA/EUROPE/Locations Not Listed:

Motorola Literature Distribution  
P.O. Box 5405  
Denver, Colorado 80217  
Phone: 1-800-441-2447 or 1-303-675-2140

##### JAPAN:

Motorola Japan Ltd.  
SPS, Technical Information Center  
3-20-1, Minami-Azabu, Minato-ku  
Tokyo 106-8573 Japan  
Phone: 81-3-3440-3569

##### ASIA/PACIFIC:

Motorola Semiconductors H.K. Ltd.  
Silicon Harbour Centre  
2, Dai King Street, Tai Po Industrial Estate  
Tai Po, N.T., Hong Kong

# Chapter One

## Wireless Semiconductor Solutions RF and IF Selector Guide

While Motorola is a worldwide leader in semiconductor products, there is not a category in which the selection is more diverse, or more complete, than in products designed for RF system applications. From MOS, bipolar power and signal transistors to integrated circuits, Motorola's RF components cover the entire spectrum from HF to microwave to personal communications. Yet, product expansion continues — not only to keep pace with the progressive needs of the industry, but to better serve the needs of designers for a reliable and comprehensive source of supply.

### How to Use This Selector Guide

The RF Monolithic Integrated Circuits and the RF/IF Integrated Circuits products in this guide are divided into three major functional categories: RF Front End ICs, RF/IF Subsystem ICs and Frequency Synthesis. Each of these categories is further subdivided based on circuit functionality. This structure differentiates highly integrated subsystem ICs from fundamental circuit building blocks and discrete transistors.

The Small Signal Transistors, Medium Power Transistors, Power MOSFETs, Power Bipolar Transistors, Power Amplifier Modules and CATV Distribution Amplifiers are FIRST divided into major categories by power level. SECOND, within each category parts are listed by frequency band, except for small signal and medium power transistors, which are divided by application. Small signal transistor applications are low noise, linear amplifiers, switches, and oscillators. THIRD, within a frequency band, transistors are further grouped by operating voltage and, finally, output power.

### To Replace Devices in an Existing Design

Call your local Motorola Sales Office or Distributor to determine Motorola's closest replacement device.

### Applications Assistance

Applications assistance is only a phone call away — call the nearest Semiconductor Sales office or 1-800-521-6274.

### Access Data On-Line!

Use the Motorola SPS Internet to access Motorola Semiconductor Product data at <http://mot-sps.com> or <http://mot-sps.com/rf/>. The SPS Internet provides you with instant access to data sheets, selector guide information, package outlines, on-line technical support and much more.

# RF Front End ICs

Motorola's RF Front End integrated circuit devices provide an integrated solution for the personal communications market. These devices are available in plastic SO-8, SO-16, SOT-143, TSSOP-16, TSSOP-16EP, Micro-8, TSSOP-20EP, LQFP-48 or PFP-16 packages.

## Evaluation Boards

Evaluation boards are available for RF Front End Integrated Circuits. For a complete list of currently available boards and ones in development for newly introduced product, please contact your local Motorola Distributor or Sales Office.

## RFICs

### Downconverters

Device	RF Freq. Range MHz	Supply Volt. Range Vdc	Supply Current mA (Typ)	LNA Gain dB (Typ)	LNA NF dB (Typ)	Mixer Conv. Gain dB (Typ)	Mixer NF dB (Typ)	Case No./ Package	System Applicability
MC13142 <sup>(18b)</sup>	DC to 1800	2.7 to 6.5	13.5	17	1.8	-3.0	12	751B/ SO-16	ISM, Cellular, PCS

### Upconverters/Exciters

Device	RF Freq. Range MHz	Supply Volt. Range Vdc	Supply Current mA (Typ)	Standby Current mA (Typ)	Conv. Gain dB (Typ)	Output IP3 dBm (Typ)	Case No./ Package	System Applicability
MRFIC0954 <sup>(18b)</sup>	800 to 1000	2.7 to 5.0	65	5.0	31	28	948M/ TSSOP-20EP	CDMA, TDMA, ISM
MRFIC1813 <sup>(18b)</sup>	1700 to 2000	2.7 to 4.5	25	0.1	15	11	948C/ TSSOP-16	DCS1800, PCS
MRFIC1854 <sup>(18b)</sup>	1700 to 2000	2.7 to 5.0	70	5.0	31	23	948M/ TSSOP-20EP	CDMA, TDMA, PCS

### Power Amplifiers

Device	Freq. Range MHz	Supply Volt. Range Vdc	Saturated Pout dBm (Typ)	PAE % (Typ)	Gain Pout/Pin dB (Typ)	Case No./ Package	System Applicability
MRFIC0917 <sup>(18e)</sup>	800 to 1000	2.7 to 5.5	34.5	45	22.5	978/PFP-16	GSM
MRFIC0919 <sup>(18b)</sup> ★	800 to 1000	3.0 to 5.5	35.3	48	32.3	948L/ TSSOP-16EP	GSM
MRFIC1817 <sup>(18e)</sup>	1700 to 2000	2.7 to 5.0	33.5	42	30.5	978/PFP-16	DCS1800, PCS
MRFIC1818 <sup>(18e)</sup>	1700 to 2000	2.7 to 6.0	34.5	42	31.5	978/PFP-16	DCS1800, PCS
MRFIC1819 <sup>(18b)</sup> ★	1700 to 2000	3.0 to 5.0	33	40	27	948L/ TSSOP-16EP	DCS1800, PCS
MRFIC1856 <sup>(18b)</sup> ★	800 to 1000	3.0 to 5.6	32	50	32	948M/ TSSOP-20EP	TDMA, CDMA, AMPS
	1700 to 2000		30	35	30		TDMA, CDMA, PCS

<sup>(18)</sup>Tape and Reel Packaging Option Available by adding suffix: a) R1 = 500 units; b) R2 = 2,500 units; c) T1 = 3,000 units; d) T3 = 10,000 units; e) R2 = 1,500 units; f) T1 = 1,000 units; g) R2 = 4,000 units; h) R1 = 1,000 units; i) R3 = 250 units.

## Cordless Phone Subsystem ICs

Device	V <sub>CC</sub>	I <sub>CC</sub> (Typ)	Dual Conversion Receiver	Universal Dual PLL	Compa r and Audio Interface	CVSD Compatible	Low Battery Detect	Notes	Suffix/ Case No.
MC13109A	2.0 to 5.5 V	Active Mode 6.7 mA Inactive Mode 40 μA	✓	✓	✓	–	✓	CT–0	FB/848B, FTA/932
MC13110A	2.7 to 5.5 V	Active Mode 8.5 mA Inactive Mode 15 μA	✓	✓	✓	–	✓	CT–0	FB/848B, FTA/932
MC13111A	2.7 to 5.5 V	Active Mode 8.5 mA Inactive Mode 15 μA	✓	✓	✓	–	✓	CT–0	FB/848B, FTA/932
MC13145	2.7 to 6.5 V	Active Mode 27 mA Inactive Mode 10 μA	✓	–	–	✓	–	Receiver with coilless demod CT–900	FTA/932
MC13146	2.7 to 6.5 V	Active Mode 18 mA Inactive Mode 10 μA	–	–	–	✓	–	Transmitter with VCO CT–900	FTA/977
MC33410	2.7 to 5.5 V	Active Mode 13 mA Inactive Mode 10 μA	✓	✓	–	✓	✓	Digital Baseband CT–900	FTA/932
MC33411A MC33411B	2.7 to 5.5 V	Active Mode 15 mA Inactive Mode 10 μA	✓	✓	✓	–	✓	Analog Baseband CT–900	FTA/932

## GPS Subsystem ICs

Device	RF Freq (MHz)	IF Freq (MHz)	V <sub>CC</sub> (V)	I <sub>CC</sub> (mA) (Typ)	Dual Conversion Receiver	Dual Loop PLL	Limiting Amplifier	Variable Gain IF Amplifier	Case No.
MRFIC1502	1575	9.5	4.5 to 5.5	52	✓	✓	–	–	932
MRFIC1504	1575	4.1	2.7 to 3.3	28	✓	✓	✓	✓	932

## Receivers

Device	V <sub>CC</sub>	I <sub>CC</sub> (Typ)	Sensitivity (Typ)	RF Input	IF	Mute	RSSI	Max Data Rate	Notes	Suffix/ Case No.
MC2800	1.1 to 3.0 V	1.5 mA	–110 dBm	75 MHz	455 kHz	–	✓	>1.2 kb	Pager Applications	FTA/873C
MC3356	3.0 to 9.0 V	20 mA	30 μV	150 MHz	10.7 MHz	✓	–	500 kb	Includes front end mixer/L.O.	DW/751D

## Receivers (continued)

Device	V <sub>CC</sub>	I <sub>CC</sub> (Typ)	Sensitivity (Typ)	RF Input	IF	Mute	RSSI	Max Data Rate	Notes	Suffix/ Case No.	
MC3361B	2.0 to 8.0 V	3.9 mA	2.6 μV	60 MHz	455 kHz	✓	–	>4.8 kb	Squelch and Scan	D/751B	
MC3361C	2.0 to 8.0 V	2.8 mA				✓	–			D/751B	
MC3371	2.0 to 9.0 V	3.6 mA	1.0 μV	100 MHz			✓ 60 dB			RSSI	D/751B, DTB/948F
MC3372										RSSI, Ceramic Quad Detector/Resonator	
MC3374	1.1 to 3.0 V	1.6 mA	0.5 μV	75 MHz		–	–			Low Battery Detect	FTB/873
MC13135	2.0 to 6.0 V	4.0 mA	1.0 μV	200 MHz		10.7 MHz/ 455 kHz	–		✓ 70 dB	>4.8 kb	Voltage Buffered RSSI, LC Quad Detector
MC13136					Voltage Buffered RSSI, Ceramic Quad Detector			DW/751E			
MC13150	2.5 to 6.0 V	1.7 mA	2.0 μV	500 MHz	✓		✓ 110 dB	>9.6 kb	Coilless Detector with Adjustable Bandwidth	FTB/873, FTA/977	
MC13156	2.0 to 6.0 V	5.0 mA	2.0 μV	500 MHz	–		✓ 80 dB	500 kb	CT–2 FM/Demodulator	DW/751E, FB/873	
MC13158	2.0 to 6.0 V	6.0 mA		500 MHz					>1.2 Mb	FM IF/Demodulator with split IF for DECT	FTB/873

## IFs

Device	V <sub>CC</sub>	I <sub>CC</sub> (Typ)	Sensitivity (Typ)	IF	Mute	RSSI	Max Data Rate	Notes	Suffix/ Case No.
MC13055	3.0 to 12 V	20 mA	20 μV	40 MHz	✓	✓	2.0 Mb	Wideband Data IF, includes data shaper	D/751B
MC13155	3.0 to 6.0 V	7.0 mA	1.0 mV	250 MHz	–		10 Mb	Video Speed FM IF	D/751B

## Transmitters

Device	V <sub>CC</sub>	I <sub>CC</sub> (Typ)	P <sub>out</sub>	Max RF Freq Out	Max Mod Freq	Notes	Suffix/ Case No.
MC13176	2.0 to 5.0 V	40 mA	10 dBm	1.0 GHz	5.0 MHz	f <sub>out</sub> = 32 × f <sub>ref</sub> , includes power down function, AM/FM Modulation	D/751B

## Miscellaneous Functions

### ADCs/DACs

Device	Function	I/O Format	Resolution	Number of Analog Channels	On-Chip Oscillator	Other Features	Suffix/ Case No.
MC144110	DAC	Serial	6 Bits	6	–	Emitter–Follower Outputs	DW/751D
MC144111				4			DW/751G
MC145050	ADC		10 Bits	11	–	Successive Approximation	P/738, DW/751D
MC145051				5	✓		P/646, D/751A
MC145053							

### Encoders/Decoders

Device	Function	Number of Address Lines	Maximum Number of Address Codes	Number of Data Bits	Operation	Suffix/ Case No.
MC145026	Encoder	Depends on Decoder	Depends on Decoder	Depends on Decoder	Simplex	P/648, D/751B
MC145027	Decoder	5	243	4	Simplex	P/648, DW/751G
MC145028		9	19,683	0	Simplex

## Single PLL Synthesizers

Maximum Frequency (MHz)	Supply Voltage (V)	Nominal Supply Current (mA)	Features	Device	Suffix/Case
20 @ 5.0 V	3.0 to 9.0	7.5 @ 5 V	Parallel Interface	MC145151-2	DW/751F
20 @ 5.0 V	3.0 to 9.0	7.5 @ 5 V	Parallel Interface, Uses External Dual-Modulus Prescaler	MC145152-2	DW/751F
20 @ 5.0 V	3.0 to 9.0	7.5 @ 5 V	Serial Interface	MC145157-2	DW/751G
20 @ 5.0 V	3.0 to 9.0	7.5 @ 5 V	Serial Interface, Uses External Dual-Modulus Prescaler	MC145158-2	DW/751G
100 @ 3.0 V 185 @ 4.5 V	2.7 to 5.5	2 @ 3 V 6 @ 5 V	Serial Interface, Auxiliary Reference Divider, Evaluation Kit – MC145170EVK	MC145170-2	P/648, D/751B, DT/948C
1000	2.7 to 5.5	4.25	4-Line Parallel Interface	MC12181	D/751B
1100	2.7 to 5.5	7 @ 5 V	Serial Interface, Standby, Auxiliary Reference Divider, Evaluation Kit – MC145191EVK	MC145193 <sup>(46a)</sup>	F/751J, DT/948D
2000	2.7 to 5.5	4 @ 3 V	Serial Interface, Standby, Auxiliary Reference Device, Evaluation Kit – MC145202EVK	MC145202-1 <sup>(46a)</sup>	F/751J, DT/948D
2500	2.7 to 5.5	9.5	Serial Interface	MC12210	D/751B, DT/948E
2800	4.5 to 5.5	3.5	Fixed Divider	MC12179	D/751

<sup>(46)</sup>To be introduced: a) 1Q00; b) 2Q00; c) 3Q00

## Dual PLL Synthesizers

Maximum Frequency (MHz)	Supply Voltage (V)	Nominal Supply Current (mA)	Phase Detector	Device	Suffix/Case
60 @ 3.0 V both loops	2.5 to 5.5	3 @ 3 V	Serial Interface, Standby	MC145162	P/648, D/751B
85 @ 3.0 V both loops	2.5 to 5.5	3 @ 3 V	Serial Interface, Standby	MC145162-1	D/751B
550, 60	1.8 to 3.6	3	10 MHz Serial Interface, Multiple Standby Modes, Dual 8-Bit DACs, Voltage Multiplier for Phase Detectors (See Note).	MC145181	FTA/873C
1100 both loops	2.7 to 5.5	12	Serial Interface, Standby, Evaluation Kit – MC145220EVK	MC145220	F/803C, DT/948D
1200, 550	1.8 to 3.6	4	10 MHz Serial Interface, Multiple Standby Modes, Dual 8-Bit DACs, Voltage Multiplier for Phase Detectors (See Note).	MC145225	FTA/873C
2200, 550	1.8 to 3.6	5	10 MHz Serial Interface, Multiple Standby Modes, Dual 8-Bit DACs, Voltage Multiplier for Phase Detectors (See Note).	MC145230	FTA/873C

**NOTE:** The MC145230EVK development system may be used with the MC145181, MC145225, or MC145230. The MC145230 is soldered to a tested board; MC145181, MC145225 and MC145230 device samples are included. The user must supply the VCOs for the MC145181.

# PLL Building Blocks

## Prescalers

Frequency (MHz)	Divide Ratios	Single or Dual Modulus	Supply Voltage (V)	Supply Current (mA)	Features	Device	Suffix/Case
1100	64/65, 128/129	Dual	2.7 to 5.5	2.0 max	Low Power	MC12052A	D/751
1100	64/65, 128/129	Dual	2.7 to 5.5	2.5 max	Low Power, Standby	MC12053A	D/751
1100	126/128, 254/256	Dual	2.7 to 5.5	2.0 max	Low Power	MC12058	D/751
1100	10,20,40,80	Single	4.5 to 5.5	5.0 max		MC12080	D/751
1100	2, 4, 8	Single	2.7 to 5.5	4.5 max	Standby	MC12093	D/751
2000	64/65, 128/129	Dual	2.7 to 5.5	2.6 max	Low Power	MC12054A	D/751
2500	2, 4	Single	2.7 to 5.5	14 max	Standby	MC12095	D/751
2800	64, 128, 256	Single	4.5 to 5.5	11.5 max		MC12079	D/751
2800	64, 128	Single	4.5 to 5.5	14.5 max		MC12089	D/751

## Voltage Control Oscillators

Frequency (MHz)	Supply Voltage (V)	Features	Device	Suffix/Case
1300	2.7 to 5.5	Two high drive open collector outputs (Q, QB), Adjustable output amplitude, Low drive output for prescaler	MC12149	D/751

## Phase–Frequency Detectors

Frequency (MHz)	Supply Voltage (V)	Features	Device	Suffix/Case
800 (Typ)	4.75 to 5.5	MECL10H compatible	MCH12140	D/751
800 (Typ)	4.2 to 5.5	100K ECL compatible	MCK12140	D/751

# Motorola RF Discrete Transistors

Motorola offers the most extensive group of RF Discrete Transistors offered by any semiconductor manufacturer anywhere in the world today.

From Bipolar to FET, from Low Power to High Power, the user can choose from a variety of packages. They include plastic and ceramic that are microstrip circuit compatible or surface mountable. Many are designed for automated assembly equipment.

Major sub-headings are Small Signal, Medium Power, Power MOSFETs and Bipolar Transistors.

# Motorola RF Small Signal Transistors

Motorola's broad line of RF Small Signal Transistors includes NPN Silicon Bipolar Transistors characterized for low noise amplifiers, mixers, oscillators, multipliers, non-saturated switches and low-power drivers.

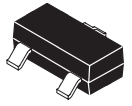

These devices are available in a variety of package types. Most of these transistors are fully characterized with s-parameters.

# Motorola RF Medium Power Transistors

RF Medium Power Transistors are used in portable transmitter applications and low voltage drivers for higher power devices. They can be used for analog cellular, GSM and the newer digital handheld cellular phones. GaAs, LDMOS and Bipolar devices are available. RF Medium Power Transistors are supplied in Motorola's high performance PLD line of surface mount power RF packages. Other applications include talkback pagers, wireless modems and LANs, cable modems, highspeed drivers and instrumentation.

## Discrete Wireless Transmitter Devices

# Motorola RF High Power Transistors

## RF Power MOSFETs

Motorola RF Power MOSFETs are constructed using a planar process to enhance manufacturing repeatability. They are *N-channel field effect transistors* with an oxide insulated gate which controls vertical current flow.

Compared with bipolar transistors, RF Power FETs exhibit higher gain, higher input impedance, enhanced thermal stability and lower noise. The FETs listed in this section are specified for operation in RF Power Amplifiers and are grouped by frequency range of operation and type of application. Arrangement within each group is first by order of voltage then by increasing output power.

# RF Power Bipolar Transistors

Motorola's broad line of bipolar RF power transistors are characterized for operation in RF power amplifiers. Typical applications are in base stations, military and commercial landmobile, avionics and marine radio transmitters. Groupings are by frequency band and type of application. Within each group, the arrangement of devices is by major supply voltage rating, then in the order of increasing output power. All devices are NPN polarity except where otherwise noted.

## UHF Transistors

**Table 1. 100 – 500 MHz Band**

Designed for UHF military and commercial aircraft radio transmitters.

<sup>(37)</sup>M = Matched Frequency Band; U = Unmatched Frequency Band.

## Microwave Transistors

**Table 4. L-Band Long Pulse Power**

These products are designed for pulse power amplifier applications in the 960–1215 MHz frequency range. They are capable of handling up to 10  $\mu$ s pulses in long pulse trains resulting in up to a 50% duty cycle over a 3.5 millisecond interval. Overall duty cycle is limited to 25% maximum. The primary applications for devices of this type are military systems, specifically JTIDS and commercial systems, specifically Mode S. Package types are hermetic.

Device	Frequency Band <sup>(37)</sup>	P <sub>out</sub> Watts	Gain (Min) @ 1215 MHz dB	$\theta_{JC}$ °C/W	Package/Style
<b>V<sub>CC</sub> = 28 Volts — Class C Common Base</b>

# Motorola RF Amplifier Modules

Motorola's RF portfolio includes many hybrid designs optimized to perform either in narrowband base station transmitter applications, or in broadband linear amplifiers. Motorola modules feature two or more active transistors (LDMOS, GaAs, or Bipolar die technology) and their associated 50 ohm matching networks. Circuit substrate and metallization have been selected for optimum performance and reliability. For PA designers, hybrid modules offer the benefits of small and less complex system designs, in less time and at a lower overall cost.

# Motorola RF Amplifier Modules/ICs

Complete amplifiers with 50 ohm input and output impedances are available for all popular base station transmitter systems, including GSM and CDMA, covering frequencies from 800 MHz up to 2.2 GHz.

## Base Stations

Designed for applications such as macrocell drivers and microcell output stage, these class AB amplifiers are ideal for GSM base station systems at 900, 1800 and 1900 MHz, with power requirements up to 16 watts.

**Table 1. Base Stations**

Device	Frequency MHz	P <sub>out</sub> Watts	Gain (Min) dB	Supply Voltage Volts	Class	System Application	Die Technology	Package/Style
MHVIC910L <sup>(46b)</sup>	921–960	10	22	26	AB	GSM900	LDMOS–IC	978/–

MHW1915	1930–1990	15	29	26	AB	GSM1900	Silicon Bipolar	301AK/1

**Table 2. Base Station Drivers**

These 50 ohm amplifiers are recommended for modern multi–tone CDMA, TDMA and UMTS base station pre–driver applications. Their high third–order intercept point, tight phase and gain control, and excellent group delay characteristics make these devices ideal for use in high–power feedforward loops.

## Wideband Linear Amplifiers

**Table 1. Standard 50 Ohm Linear Hybrid**

This series of RF linear hybrid amplifier has been optimized for wideband, 50 ohm applications. These amplifiers were designed for multi-purpose RF applications where linearity, dynamic range and wide bandwidth are of primary concern. The MHL series utilizes a new case style that provides microstrip input and output connections.

## RF Front End ICs

Motorola's RF Front End integrated circuit devices provide an integrated solution for the personal communications market. These devices are available in plastic SO-8, SO-16, SOT-143, TSSOP-16, TSSOP-16EP, Micro-8, TSSOP-20EP, LQFP-48 or PFP-16 packages.

### Evaluation Boards

Evaluation boards are available for RF Front End Integrated Circuits. For a complete list of currently available boards and ones in development for newly introduced product, please contact your local Motorola Distributor or Sales Office.

## Advance Information

# Low Power DC - 1.8 GHz LNA, Mixer and VCO

The MC13142 is intended to be used as a first amplifier, voltage controlled oscillator and down converter for RF applications. It features wide band operation, low noise, high gain and high linearity while maintaining low current consumption. The circuit consists of a Low Noise Amplifier (LNA), a Voltage Controlled Oscillator (VCO), a buffered oscillator output, a mixer, an Intermediate Frequency amplifier (IF<sub>amp</sub>) and a dc control section. The wide mixer IF bandwidth allows this part also to be used as an up converter and exciter amplifier.

- Wide RF Bandwidth: DC–1.8 GHz
- Wide LO Bandwidth: DC–1.8 GHz
- Wide IF Bandwidth: DC–1.8 GHz
- Low Power: 13 mA @ V<sub>CC</sub> = 2.7 – 6.5 V
- High Mixer Linearity: P<sub>i1.0</sub> dB = 3.0 dBm
- Linearity Adjustment Increases IP<sub>3in</sub> Up to 20 dBm
- Single-Ended 50 Ω Mixer Input
- Double Balanced Mixer Operation
- Open Collector Mixer Output
- Single Transistor Oscillator with Collector, Base and Emitter Pinned Out
- Buffered Oscillator Output

# MC13142

## CIRCUIT DESCRIPTION

### General

The MC13142 is a low power LNA, double-balanced Mixer, and VCO. This device is designated for use as the frontend section in analog and digital FM systems such as Digital European Cordless Telephone (DECT), PHS, PCS, Cellular, UHF and 800 MHz Special Mobile Radio (SMR), UHF Family Radio Services and 902 to 928 MHz cordless telephones. It features a mixer linearity control to preset or auto program the mixer dynamic range, an enable function and a wideband IF so the IC may be used either as a down converter or an up converter. Further details are covered in the Pin by Pin Description which shows the equivalent internal circuit and external circuit requirements.

### Current Regulation/Enable

Temperature compensating voltage independent current regulators are controlled by the enable function in which "high" powers up the IC.

### Low Noise Amplifier (LNA)

The LNA is internally biased at low supply current (approximately 2.0 mA emitter current) for optimal noise figure and gain. The LNA output is biased internally with a 600  $\Omega$  resistor to  $V_{CC}$ . Input and output matching may be achieved at various frequencies using few external components. Matching the LNA for Maximum stable gain

(MSG) yields noise performance within a few tenths of a dB of the minimum noise figure.

### Mixer

The mixer is a double-balanced four quadrant multiplier biased class AB allowing for programmable linearity control via an external current source. An input third order intercept point of 20 dBm may be achieved. All 3 ports of the mixer are designed to work up to 1.8 GHz. The mixer has a 50  $\Omega$  single-ended RF input and open collector differential IF outputs. An on-board Local Oscillator transistor has the emitter, base and collector pinned out to implement a low phase noise VCO in various configurations. Additionally, a buffered LO output is provided for operation with a frequency synthesizer. The linear gain of the mixer is approximately 0 dB with a SSB noise figure of 12 dB in the IF output circuit configuration shown in the application example.

### Local Oscillator

The on-chip transistor operates with coaxial transmission line or LC resonant elements to over 2.0 GHz. Biasing is done with a temperature compensated current source in the emitter and a collector to base internal resistor of 7.6 k $\Omega$ ; however, an RFC from  $V_{CC}$  to base is recommended. The application circuit shows a voltage controlled Clapp oscillator operating at center frequency of 975 MHz.

# MC13142

## PIN FUNCTION DESCRIPTION

Pin	Symbol	Equivalent Internal Circuit (20 Pin LQFP)	Description
16 Pin SOIC			
1	EN		<p><b>Enable, E Osc</b> In SO-16, both enables, (for the Oscillator/LO Buffer and LNA/Mixer) are bonded to Pin 1. Enable by pulling up to <math>V_{CC}</math> or to greater than <math>2.0 V_{BE}</math>.</p>
2	RF <sub>in</sub>		<p><b>RF Input</b> The input is the base of an NPN low noise amplifier. Minimum external matching is required to optimize the input return loss and gain.</p>
3	V <sub>EE</sub>		<p><b>V<sub>EE</sub> – Negative Supply</b> <math>V_{EE}</math> pin is taken to an ample dc ground plane through a low impedance path. The path should be kept as short as possible. A two sided PCB is implemented so that ground returns can be easily made through via holes.</p>
16	RF <sub>out</sub>		<p><b>RF Output</b> The output is from the collector of the LNA; it is internally biased with a <math>600 \Omega</math> resistor to <math>V_{CC}</math>. As shown in the 926 MHz application receiver the output is conjugately matched with a shunt L, and series L and C network.</p>
4 5 6	Osc E Osc B Osc C		<p><b>On-Board VCO Transistor</b> The transistor has the emitter, base and collector + <math>V_{CC}</math> pins available. Internal biasing which is compensated for stability over temperature is provided. It is recommended that the base pin is pulled up to <math>V_{CC}</math> through an RFC chosen for the particular oscillator center frequency. The application circuit shows a modified Colpitts or Clapp oscillator configuration and its design is discussed in detail in the application section.</p>
6 8	V <sub>CC</sub> V <sub>CC</sub>		<p><b>Supply Voltage (<math>V_{CC}</math>)</b> Two <math>V_{CC}</math> pins are provided for the Local Oscillator and LO Buffer Amplifier. The operating supply voltage range is from 2.7 Vdc to 6.5 Vdc. In the PCB layout, the <math>V_{CC}</math> trace must be kept as wide as feasible to minimize inductive reactances along the trace. <math>V_{CC}</math> should be decoupled to <math>V_{EE}</math> at the IC pin as shown in the component placement view.</p>
7	LO Buff		<p><b>Local Oscillator Buffer</b> This is a buffered output providing <math>-16</math> dBm (<math>50 \Omega</math> termination) to drive the <math>f_{IN}</math> pin of a PLL synthesizer. Impedance matching to the synthesizer may be necessary to deliver the optimal signal and to improve the phase noise performance of the VCO.</p>

# MC13142

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Equivalent Internal Circuit (20 Pin LQFP)	Description
9, 12	$V_{EE}$		<p><b><math>V_{EE}</math>, Negative Supply</b> These pins are <math>V_{EE}</math> supply for the mixer IF output. In the application PC board these pins are tied to a common <math>V_{EE}</math> trace with other <math>V_{EE}</math> pins.</p>
10, 11	IF-, IF+		<p><b>IF Output</b> The IF is a differential open collector configuration which designed to use over a wide frequency range for up conversion as well as down conversion. Differential to single-ended circuit configuration and matching options are discussed in the application section. 6.0 dB of additional Mixer gain can be achieved by conjugately matching at the desired IF frequency.</p>
13	$RF_m$		<p><b>Mixer RF Input</b> The mixer input impedance is broadband <math>50\ \Omega</math> for applications up to 1.8 GHz. It easily interfaces with a RF ceramic filter as shown in the application schematic.</p>
14	Mix Lin Cont		<p><b>Mixer Linearity Control</b> The mixer linearity control circuit accepts approximately 0 to 2.3 mA control current to set the dynamic range of the mixer. An Input Third Order Intercept Point, IIP3 of 20 dBm may be achieved at 2.3 mA of control current (approximately 7.0 mA of additional supply current).</p>
15	$V_{CC}$		<p><b><math>V_{CC}</math>, Power Supply</b></p>

# MC13142

## APPLICATIONS INFORMATION

### Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The PC board accommodates all SMT components on the circuit side (see Circuit Side Component Placement View). This evaluation board will be discussed and referenced in this section.

### Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers. The circuit side placement view is illustrated for the components specified in the application circuit. The application circuit schematic specifies particular components that were used to achieve the results given and specified in the tables but alternate components of the same Q and value should give equivalent results.

**Figure 1. Application Circuit**  
(926.5 MHz)

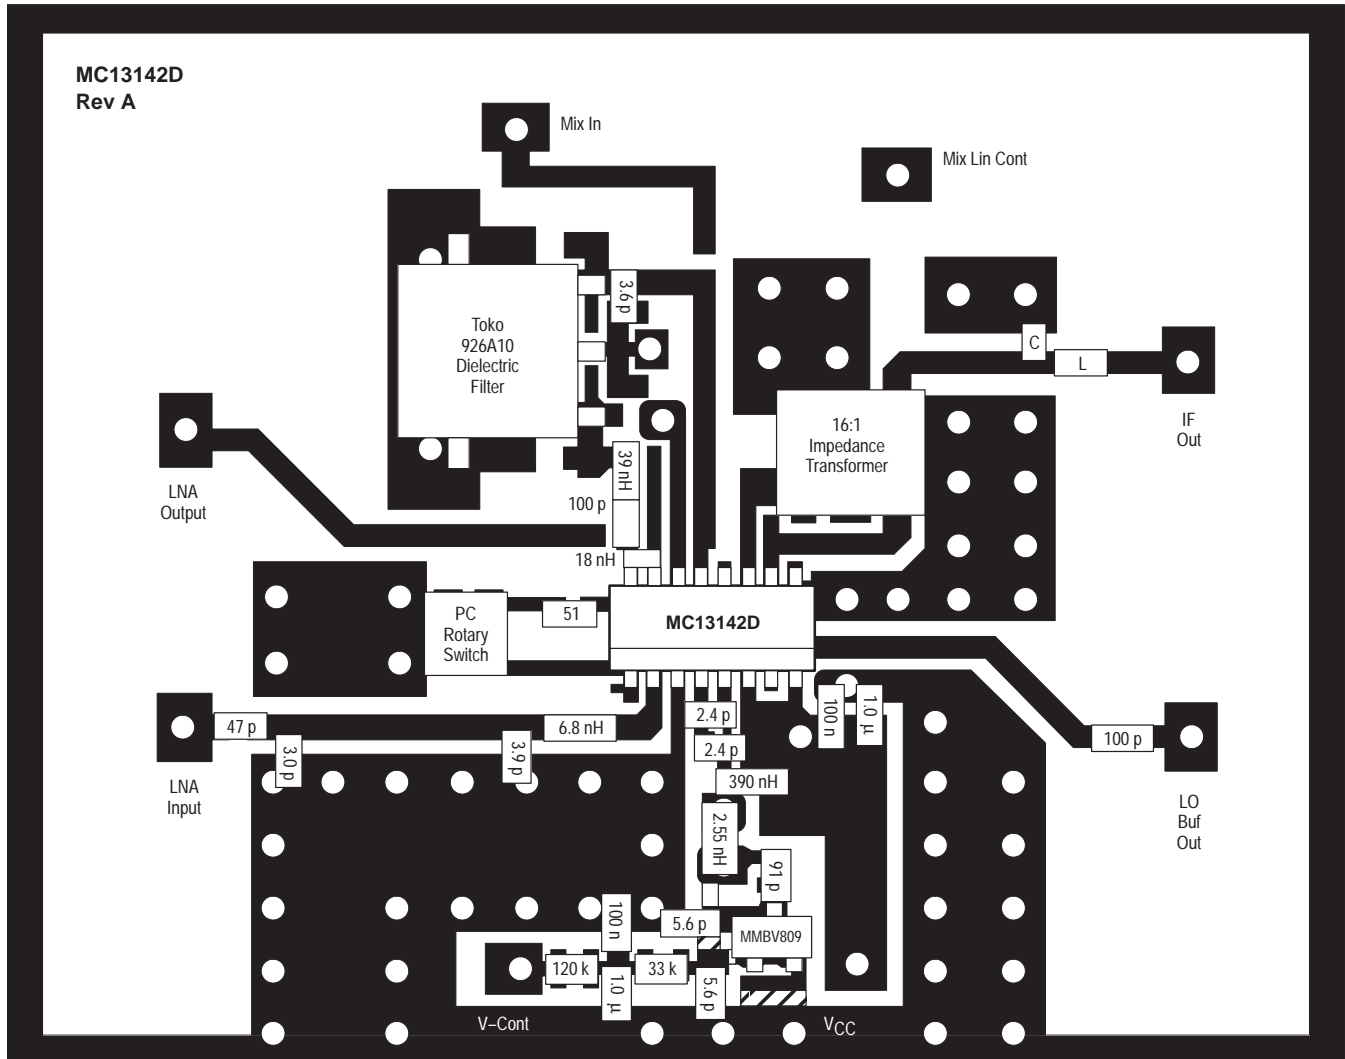

**NOTE:** \*50 Ω Microstrip Transmission Line; length shown in Figure 2.

# MC13142

Figure 2. 900 MHz Circuit Side Component Placement View

**NOTES:** The PCB is laidout for the 4DFA (2 pole SMD type) and 4DFB (3 pole SMD type) filters which are available for applications in cellular and GSM, GPS (1.2–1.5 GHz), DECT, PHS and PCS (1.8–2.0 GHz) and ISM Bands (902–928 MHz and 2.4–2.5 GHz). In the component placement shown above, the 926.5 MHz dielectric type image filter is used (Toko Part # 4DFA–926A10).

The PCB also accommodates a surface mount SAW filter in an eight or six pin ceramic package for the cellular base and handset frequencies. Recommended manufacturers are Siemens and Murata.

Traces are provided on the PCB to evaluate the LNA and mixer separately. The component placement view shows external circuit components used for the 926.5 MHz application circuit. Note: some traces must be cut to accommodate placement of components; likewise some traces must be shorted. The voltage controlled oscillator is shown with the varactor referenced to  $V_{EE}$  ground. The PCB is modified as shown to do this.

16:1 broadband impedance transformer is mini circuits part #TX16–R3T; it is in the leadless surface mount "TX" package. Components L and C comprise a low pass filter used to provide narrowband matching at a given IF frequency. For example at 49 MHz  $C = 36$  p and  $L = 330$  nH.

The microstrip trace on the ground side of the PCB is intended for a microstrip resonator; it is cut free when using a lump inductor as done above.

**Input Matching/Components**

It is desirable to use a RF ceramic or SAW filter before the mixer to provide image frequency rejection. The filter is selected based on cost, size and performance tradeoffs. Typical RF filters have 3.0 to 5.0 dB insertion loss. The PC board layout accommodates both ceramic and SAW RF filters which are offered by various suppliers such as Siemens, Toko and Murata.

Interface matching between the LNA, RF filter and the mixer will be required. The interface matching networks shown in the application circuit are designed for 50 Ω interfaces.

In the application circuit, the LNA is conjugately matched to 50 Ω input and output for 3.0 to 5.0 Vdc V<sub>CC</sub>. 17 dB gain and 1.8 dB noise figure is typical at 926 MHz. The mixer measures 0 dB gain and 12 dB noise figure as shown in the application circuit. Typical insertion loss of the Toko ceramic filter is 3.0 dB. Thus, the overall gain of the frontend receiver is 14 dB with a 3.3 dB noise figure.

**System Noise Considerations**

The block diagram shows the cascaded noise stages of the MC13142 in the frontend receiver subsystem; it

represents the application circuit. In the cascaded noise analysis the system noise equation is:

$$F_{system} = F1 + [(F2 - 1)/G1] + [(F3 - 1)/((G1)(G2))]$$

where:

- F1 = the Noise Factor of the MC13142 LNA
- G1 = the Gain of the LNA
- F2 = the Noise factor of the RF Ceramic Filter
- G2 = the Gain of the Ceramic Filter
- F3 = the Noise factor of the Mixer

**Note:** the above terms are defined as linear relationships and are related to the log form for gain and noise figure by the following:

$$F = \text{Log}^{-1} [(NF \text{ in dB})/10] \text{ and similarly}$$

$$G = \text{Log}^{-1} [(Gain \text{ in dB})/10].$$

Calculating in terms of gain and noise factor yields the following:

$$F1 = 1.51; G1 = 50.11$$

$$F2 = 1.99; G2 = 0.5$$

$$F3 = 15.85$$

Thus, substituting in the equation for system noise factor:

$$F_{system} = 2.12; NF_{system} = 3.3 \text{ dB}$$

## 1.9 GHz FRONT-END FOR WIRELESS SYSTEMS

This application is applicable to both Analog and Digital systems. With the correct VCO tuning and the appropriate filter, it will do the front-end for DECT, PHS or PCS. The MC13142D is available in a SOIC 16 pin package. The part requires minimal external components, leading to a low cost system. A circuit board layout with a circuit diagram to evaluate the IC is shown. Except for the PLL control, all the wireless systems front-ends will look the same and have the same basic performance characteristic as the test circuit.

### Circuit Operation:

#### LNA Input/Output

An LC filter is incorporated before the LNA to provide some selectivity. In addition to selectivity, its other function is to match the antenna impedance ( $50\ \Omega$ ) to the LNA input for best gain and sensitivity (low noise figure). The network reflects about a  $200\ \Omega$  source impedance to the device.

The output circuit is a pie network consisting of; the LNA output capacity, the inductance (the bond wire, package pin and L2), and the input capacity of the dielectric filter, along with some added shunt. A  $2.4\ \text{pF}$  with Toko 4DFA 2 pole filter. The  $2.4\ \text{pF}$  is for matching the in-band filter impedance to the LNA output and has little effect on tuning.

Both networks are tuned to band center by adjusting L1 and L2. L1 and L2, as well as L3, are short length of wire formed in a half loop. Once the correct length is determined in

centering the tuning range, adjustment is accomplished by moving the loop toward or away from some conductive surface such as a ground plane.

The dielectric filter is referenced to the dc supply which lessen the parts count and adds distributive capacity for high frequency bypassing. DC feed to the LNA is through a low value resistor ( $220$  to  $330\ \Omega$ ) tapped at the filter input, so as not to load the circuit unnecessarily. There is a small voltage drop across the resistor, as well as some signal loss. The signal loss is about  $0.73\ \text{dB}$  for a  $220\ \Omega$  resistor and less for larger values. If one can not afford the voltage drop, an inductor could replace the resistor at a somewhat increased cost.

#### Mixer

Looking from the dielectric filter's output, the Mixer input is  $50\ \Omega$  in series with an inductor. This inductor consists of the printed circuit run, the package pin and bond wire, all in series. It is modified, to some extent, by the package pin distributive capacity, but overall at the bandpass frequency remains inductive. Matching the filter impedance to the Mixer input only requires a capacitor with a value that, when placed in series, will resonate with this inductor at the filter bandpass frequency.

The single-ended input signal is converted internally into balanced current signals. The two signals drive the two low impedance inputs (emitters) of a Gilbert Cell. They appear as

## MC13142

current sources to the Cell and can be programmed (via Pin 15) for more current. The current is often adjusted for minimum third order response. In this Fixture it is fixed biased for most conversion gain.

The Mixer circuit is balanced where both oscillator and RF are suppressed. This provides IF signals at Pins 9 and 10 which are equal in amplitude and 180 degrees out of phase. To realize a positive gain one needs to reflect a higher impedance from the load impedance ( $50\ \Omega$  for this fixture) to the Mixer output or outputs. Maximum signal transfer would require a balance to unbalance network. Center tapped tuned transformers can perform this function but are quite expensive. If one can afford 3.0 dB less signal, a simple LC circuit at one of the outputs will work well. The other output is unused and bypassed to ground.

The most gain is realized when no shunt capacity is added and L4 is selected to resonate with the terminal capacity. Adding shunt capacity will lower the gain and increase the circuit's bandwidth. A small value series capacitor C4 to the  $50\ \Omega$  output will control the reflected impedance and complete the circuit. L4 and C4 will vary in value depending on the IF frequency.

### VCO

The base of the device is the source for driving both the Gilbert cell and prescaler buffer stages. Because of this, the oscillator device will operate and drive the Mixer only in the grounded collector configuration. Additional dc bias is added through a  $1.3\ \text{k}\Omega$  resistor (tapped for minimum VCO loading) to reduce the off-set between base and supply.

The external circuit is a modified Colpitts where the capacitance between base and emitter (Pins 4 and 5), along with a capacitor from emitter to ac ground, forms the circuit capacity and the feedback that sustains oscillations. The effective circuit inductance (looking from the top of the circuit, the transistor base) consist of L3 in series with varactor diode D1 and a blocking capacitor. This circuit must appear inductive for the VCO to operate properly. If the capacity is too small, the feedback ratio is reduced and the VCO can cease oscillating. When it becomes too large, it will not vary the frequency due to the limiting effect of the series loop capacitance.

In this application, the VCO is not required to cover a large tuning range. Limiting the tuning range to no more than is required to cover the band (making allowance for temperature and aging effects) will result in a VCO less susceptible to on board noise sources. To assure oscillation while controlling the tuning range the varactor (plus series capacitor) minimum capacity is chosen to be about equal to the capacity from Pin 5 (transistor base) to RF ground. The maximum tuning ratio could be no greater than 1.41 because the circuit capacity could only double whatever the upper value capacity the varactor attained. An upper limit on the varactor capacity along with the effects of the series capacitor reduces the VCO tuning range to about 1.2 times. The varactors chosen for the test fixtures were Loral KV2111.

The VCO buffer, as most emitter follower circuits, has the potential of generating a parasitic oscillation. When a collector is RF bypassed, a tuned LC circuit is formed consisting of the bypass capacitor, bond wire plus package pin inductance and the device effective output capacity. If the base is low impedance, there is normally enough distributive collector to emitter capacity for the device to oscillate in the common base mode. A simple fix without affecting the buffer otherwise, is to place a small value series resistor in the collector lead. This will lower the Q of the circuit where it cannot sustain oscillations. Without the series resistor at Pin 8 or some other damping element, the buffer will oscillate.

### PLL

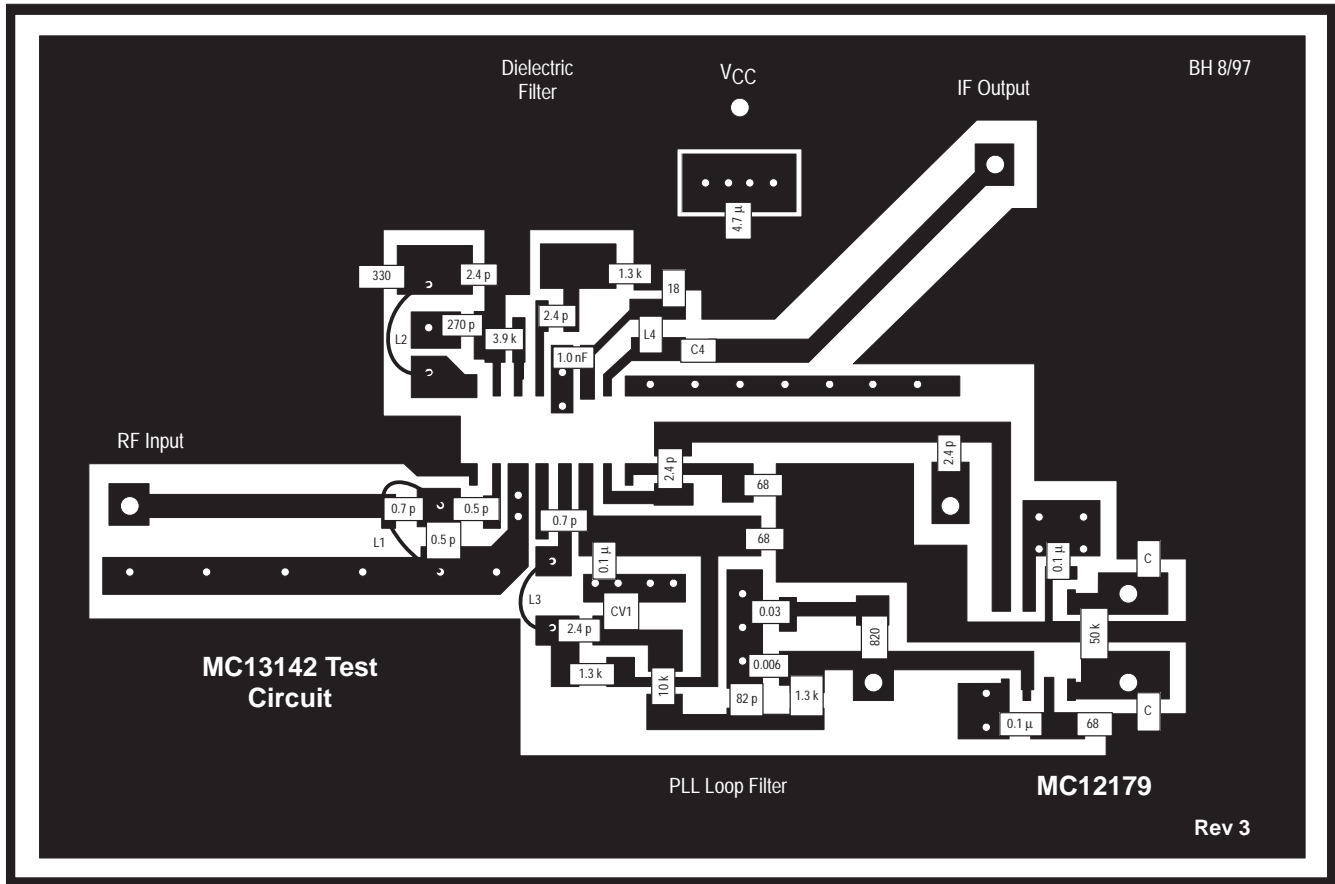

A phase lock loop is added to the test board to evaluate the VCO. The MC12179 multiplies the crystal reference frequency by 256 to obtain lock. In a frequency agile system, the MC12210 would control the VCO and its reference derived from a crystal. The crystal frequency would be selected to coincide with the required VCO frequencies and channels spacing requirements.

### Expected Performance

As stated earlier, the MC13142 performance in any of the systems should mirror the performance obtained in the test fixture. Fixture power gains of 15 dBm and noise figures of 5.5 dB are typical. The Mixer current can be varied to enhance battery life as well as alter its output characteristic for peak performance of a desired or undesired response.

Figure 7. 1.9 GHz Application Circuit

# Ultra Low Power DC - 2.4 GHz Linear Mixer

The MC13143 is a high compression linear mixer with single-ended RF input, differential IF output and differential LO inputs which consumes as little as 1.8 mW. A new circuit topology is used to achieve a high third order intermodulation intercept point, high linearity and high 1.0 dB output compression point while maintaining a linear 50 Ω input impedance. It is designed for Up or Down conversion anywhere from dc to 2.4 GHz.

### Ultra Low Power: 1.0 mA @ VCC = 1.8 to 6.5 V

- Wide Input Bandwidth: DC–2.4 GHz
- Wide Output Bandwidth: DC–2.4 GHz
- Wide LO Bandwidth: DC–2.4 GHz
- High Mixer Linearity: P<sub>1</sub>1.0 dB = 3.0 dBm

### Linearity Adjustment of up to IP<sub>3in</sub> = 20 dBm

- 50 Ω Mixer Input
- Single-Ended Mixer Input
- Double Balanced Mixer Operation
- Differential Open Collector Mixer Output

### Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The PC board is laid out to accommodate all SMT components on the circuit side (see Circuit Side Component Placement View).

### Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers. The circuit side placement view is illustrated for the components specified in the application circuit. The Component Placement View specifies particular components that were used to achieve the results shown in the typical curves and tables.

### Mixer Input

The mixer input impedance is broadband  $50\ \Omega$  for applications up to 2.4 GHz. It easily interfaces with a RF ceramic filter as shown in the application schematic.

### Mixer Linearity Control

The mixer linearity control circuit accepts approximately 0 to 2.3 mA control current. An Input Third Order Intercept Point, IIP3 of 20 dBm may be achieved at 2.3 mA of control current (approximately 7.0 mA of additional supply current).

### Local Oscillator Inputs

The differential LO inputs are internally biased at  $V_{CC} - 1.0\ V_{BE}$ ; this is suitable for high voltage and high gain operation.

For low voltage operation, the inputs are taken to  $V_{CC}$  through  $51\ \Omega$ .

### IF Output

The IF is a differential open collector configuration which is designed to use over a wide frequency range for up conversion as well as down conversion.

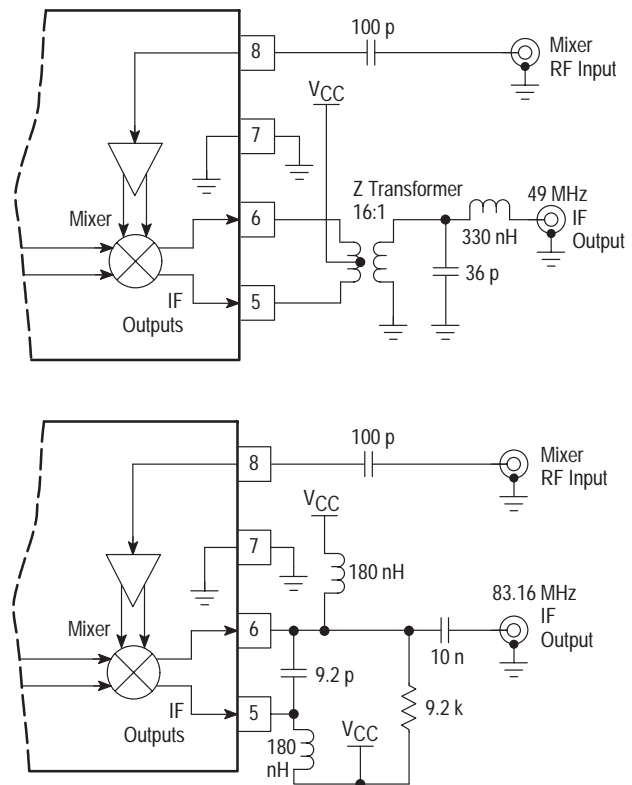

### Input/Output Matching

It is desirable to use a RF ceramic or SAW filter before the mixer to provide image frequency rejection. The filter is selected based on cost, size and performance tradeoffs. Typical RF filters have 3.0 to 5.0 dB insertion loss. The PC board layout accommodates both ceramic and SAW RF filters which are offered by various suppliers such as Siemens, Toko and Murata.

Interface matching between the RF input, RF filter and the mixer will be required. The interface matching networks shown in the application circuit are designed for  $50\ \Omega$  interfaces.

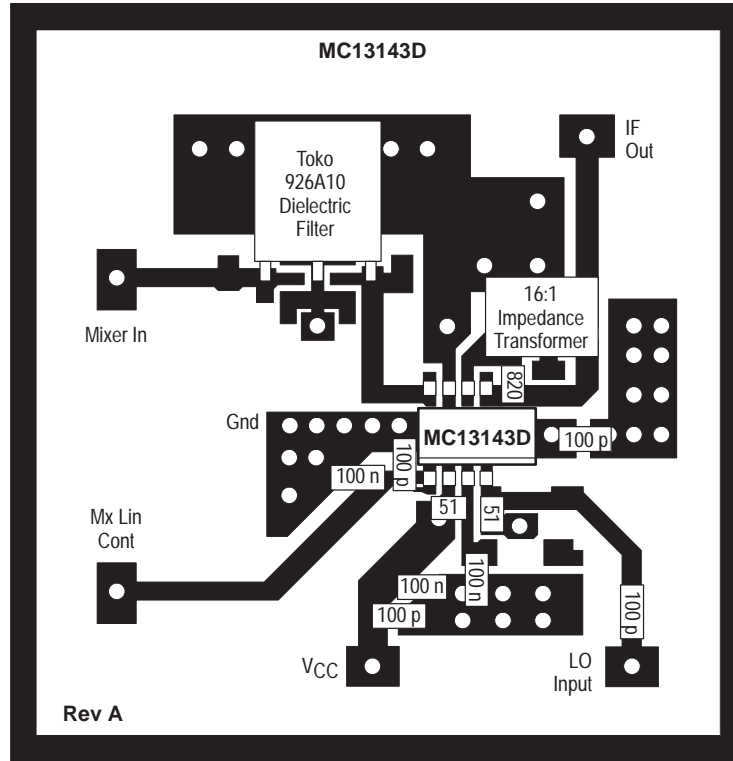

Differential to single-ended circuit configuration is shown in the test circuit. 6.0 dB of additional mixer gain can be achieved by conjugately matching the output of the MiniCircuits transformer to  $50\ \Omega$  at the desired IF frequency. With narrowband IF output matching the mixer performance is 3.0 dB gain and 12 dB noise figure (see Narrowband 49 and 83 MHz IF Output Matching Options). Typical insertion loss of the Toko ceramic filter is 3.0 dB. Thus, the overall gain of the circuit is 0 dB with a 15 dB noise figure.

**Figure 9. Narrowband IF Output Matching with 16:1 Z Transformer and LC Network**

# MC13143

Figure 10. Circuit Side Component Placement View

**NOTES:** 926.5 MHz preselect dielectric filter is Toko part # 4DFA-926A10; the 4DFA (2 and 3 pole SMD type) filters are available for applications in cellular and GSM, GPS, DECT, PHS, PCS and ISM bands at 902-928 MHz, 1.8-1.9 GHz at 2.4-2.5 GHz.

The PCB also accommodates a surface mount RF SAW filter in an eight or six pin ceramic package for the cellular base and handset frequencies. Recommended manufacturers are Siemens and Murata.

The PCB may also be used without a preselector filter; AC coupled to the mixer as shown in the test circuit schematic. All other external circuit components shown in the PCB layout above are the same as used in the test circuit schematic.

16:1 broadband impedance transformer is mini circuits part #TX16-R3T; it is in the leadless surface mount "TX" package. For a more selective narrowband match, a lowpass filter may be used after the transformer. The PCB is designed to accommodate lump inductors and capacitors in more selective narrowband matching of the mixer differential outputs to a single-ended output at a given IF frequency.

The local oscillator may also be driven in a differential configuration using a coaxial transformer. Recommended sources are the Toko Balun transformers type B4F, B5FL and B5F (SMD component).

## Advance Information

# VHF - 2.0 GHz Low Noise Amplifier with Programmable Bias

The MC13144 is designed in the Motorola High Frequency Bipolar MOSIAC V™ wafer process to provide excellent performance in analog and digital communication systems. It includes a cascoded LNA usable up to 2.0 GHz and at 1.8 Vdc, with 2 bit digital programming of the LNA bias. Targeted applications are in the UHF Family Radio Services, UHF and 800 MHz Special Mobile Radio, 800 MHz Cellular and GSM, PCS, DECT and PHS at 1.8 to 2.0 GHz and Cordless Telephones in the 902 to 928 MHz band covered by FCC Title 47; Part 15. The MC13144 offers the following features:

- 17 dB Gain at 900 MHz
- 1.4 dB Noise Figure at 900 MHz
- 1.0 dB Compression Point of  $-7.0$  dBm; Input Third Order Intercept Point of  $-5.0$  dBm
- Low Operating Supply Voltage (1.8 to 6.0 Vdc)
- Programmable Bias with Enable 1 and Enable 2
- Enable 1 and Enable 2 Programmed High for Optimal Noise Figure and Gain Associated with NF
- Can Override Enable and Externally Program In Up to 15 mA

## CIRCUIT DESCRIPTION

### General

The MC13144 is a low noise amplifier with programmable bias. This device is designated for use in the front end section in analog and digital FM systems such as Wireless Local Area Network (LAN), Digital European Cordless Telephone (DECT), PHS, PCS, GPS, Cellular, UHF and 800 MHz Special Mobile Radio (SMR), UHF Family Radio Services and 902 to 928 MHz cordless telephones.

### Current Regulation/Enable

Temperature compensating voltage independent current regulation is digitally controlled by a 2-bit programmable bias/enable circuit.

### LNA

The LNA is a unique and patented cascode amplifier with digitally (2-bit) programmable bias (see Internal Circuit Schematic). Typical gain of the LNA is 17 dB for minimum noise figure of 1.4 dB at 900 MHz.

### Programmable Bias/Enable Circuit

This unique circuit allows for 3 bias levels and a standby mode in which the LNA can be externally biased as desired.

**Figure 1. MC13144 Internal Circuit\***

**NOTE:** \* The MC13144 uses a unique and patent pending circuit topology.

# MC13144

## APPLICATIONS INFORMATION

### Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The PC board layout accommodates all SMT components on the circuit side (see Circuit Side Component Placement View).

### Component Selection

The evaluation PC board is laid out for the 4DFA (2 pole SMD Type) and 4DFB (3 pole SMD Type) filters which are available for applications in Cellular and GSM, GPS (1.2 to 1.5 GHz), DECT, PHS and PCS (1.8 to 2.0 GHz) and ISM Bands (902 to 928 MHz and 2.4 to 2.5 GHz). In the 926.5 MHz Application Circuit, a ceramic dielectric filter is used (Toko part # 4DFA-926A10).

### LNA Input/Output

The LNA input impedance is the base of a common emitter cascode amplifier. The LNA output is the collector of the cascode stage and it is loaded with a series resistor of 400  $\Omega$  and a capacitor of 10 pF to provide stability.

### Digitally Programmable Bias/Enable

The LNA is enabled by a 2 bit (En1 and En2) programmable bias circuit. The internal circuit shows the comparator circuit which programs the internal regulator. The logic table below shows the bias and typical performance.

f = 900 mHz

I <sub>CC</sub> /Gain	En2 Low	En2 High
En1 Low	0 mA/-22 dB	1.2 mA/9.2 dB
En1 High	3.4 mA/13 dB	8.2 mA/17 dB

f = 1900 mHz

En1 High	3.4 mA/10 dB	8.2 mA/13 dB

### Input/Output Matching

A typical application at 900 MHz yields 17 dB gain and 1.4 dB noise figure. In this circuit a series inductor of 5.6 nH is used to match the input and a shunt inductor of 8.2 nH which also serves as an RFC and a series capacitor of 0.9 pF is used to match the LNA output to 50  $\Omega$  load impedance.

It may be desirable to use a RF ceramic or SAW filter after the LNA when driving a mixer to provide image frequency rejection. The image filter is selected based on cost, size and performance tradeoffs. Typical RF filters have 3.0 to 5.0 dB insertion loss. Interface matching between the RF input, RF filter and the mixer is shown in Application Circuit and the Component Placement View.

A typical application at 1900 MHz yields 13 dB gain and 2.7 dB noise figure. In this circuit a series inductor of 5.6 nH and a series capacitor of 1.0 pF are used to match the input and a shut inductor of 2.0 nH and a series capacitor of 2.0 pF are used to match the LNA output to 50  $\Omega$  load impedance.

## The MRFIC Line General Purpose RF Cascode Amplifier

The MRFIC0915 is a cost-effective, high isolation cascode silicon monolithic amplifier in the industry standard SOT-143 surface mount package designed for general purpose RF applications. The device is a lower current version of the MRFIC0916 and is appropriate for VCOs, VCO buffers and amplifiers. On-chip bias circuitry sets the bias point while matching is accomplished off chip affording the maximum in application flexibility.

- Usable Frequency Range = 100 to 2500 MHz
- Good Small Signal Gain at  $V_{CC} = 2.7$  Volts
  - 16.2 dB Typ at 850 MHz
  - 9.6 dB Typ at 1800 MHz
  - 5.8 dB Typ at 2400 MHz
- -4.6 dBm typical Output Power at 1 dB Gain Compression at 850 MHz,  $V_{CC} = 2.7$  Volts
- 38 dB Typical Reverse Isolation at 850 MHz
- 2.5 mA Max Bias Current at  $V_{CC} = 2.7$  Volts
- 2.7 to 5 Volt Supply
- Order MRFIC0915T1 for Tape and Reel.  
T1 Suffix = 3.000 Units per 8 mm, 7 inch Reel.
- Device Marking = 22

Table 4. Typical Noise Parameters (50  $\Omega$  System)

**MOTOROLA**

# General Purpose RF Cascode Amplifier

The MRFIC0916 is a cost-effective, high isolation cascode silicon monolithic amplifier in the industry standard SOT-143 surface mount package designed for general purpose RF applications. On chip bias circuitry sets the bias point while matching is accomplished off chip affording the maximum in application flexibility.

- Usable Frequency Range = 100 to 2500 MHz
- 18.5 dB typical gain at 850 MHz,  $V_{CC} = 2.7\text{ V}$
- 2.3 dBm typical Output Power at 1.0 dB Gain Compression at 850 MHz,  $V_{CC} = 2.7\text{ V}$
- 44 dB Typical Reverse Isolation at 850 MHz
- 5.6 mA Max Bias Current at  $V_{CC} = 2.7\text{ V}$
- 2.7 to 5.0 V Supply

## MAXIMUM RATINGS ( $T_A = 25^\circ\text{C}$ , unless otherwise noted)

Rating	Symbol	Value	Unit
Supply Voltage	$V_{CC}$	6.0	Vdc
RF Input Power	$P_{RF}$	10	dBm
Power Dissipation	$P_{DIS}$	100	mW
Supply Current	$I_{CC}$	20	mA
Thermal Resistance, Junction to Case	$R_{\theta JC}$	250	C/W
Storage Temperature Range	$T_{stg}$	-65 to 150	$^\circ\text{C}$
Operating Case Temperature	$T_C$	-40 to 100	$^\circ\text{C}$

**NOTE:** Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables.

## RECOMMENDED OPERATING CONDITIONS

Characteristic	Symbol	Min	Typ	Max	Unit
RF Frequency	$f_{RF}$	100	-	2500	MHz
Supply Voltage	$V_{CC}$	2.7	-	5.0	Vdc

**ELECTRICAL CHARACTERISTICS** ( $V_{CC} = 2.7\text{ V}$ ,  $T_A = 25^\circ\text{C}$ ,  $f_{RF} = 850\text{ MHz}$ , Tested in Circuit Shown in Figure 1, unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
Small Signal Gain		16.5	18.5	20.5	dB
Noise Figure		-	1.9	-	dB
Power Output at 1.0 dB Gaim Compression		0	2.3	-	dBm
Output 3rd Order Intercept Point		-	11	-	dBm
Reverse Isolation		-	44	-	dB
Supply Current		3.8	4.7	5.6	mA

The MRFIC Line  
**900 MHz GaAs Integrated Power Amplifier**

This integrated circuit is intended for GSM class IV handsets. The device is specified for 2.5 Watts output power and 43% minimum power added efficiency under GSM signal conditions at 3.6 Volt supply voltage. To achieve this superior performance, Motorola's planar GaAs MESFET process is employed. The device is packaged in the PFP-16 Power Flat Pack package which gives excellent thermal performance through a solderable backside contact.

- Usable Frequency Range 800 to 1000 MHz
- Typical Output Power: 34.5 dBm @ 3.6 Volts
- 43% Minimum Power Added Efficiency
- Low Parasitic, High Thermal Dissipation Package
- Order MRFIC0917R2 for Tape and Reel.  
R2 Suffix = 1,500 Units per 16 mm, 13 inch Reel.
- Device Marking = M0917

## APPLICATIONS INFORMATION

### Design Philosophy

The MRFIC0917 is a two-stage Integrated Power Amplifier designed for use in cellular phones, especially for those used in GSM Class IV, 3.6 V operation. Due to the fact that the input, output and some of the interstage matching is accomplished off chip, the device can be tuned to operate anywhere within the 800 to 1000 MHz frequency range.

This capability makes the MRFIC0917 suitable for portable cellular applications such as:

- 3.6 V 900 MHz DAMPS
- 3.6 V 900 MHz PDC

### RF Circuit Considerations

The MRFIC0917 can be tuned by changing the values and/or positions of the appropriate external components. Refer to Figure 2, a typical GSM Class IV applications circuit.

The input match is a shunt-C, series-L, low-pass structure and can be retuned as desired with the only limitation being the on-chip 12 pF blocking capacitor. For saturated applications such as GSM and analog cellular, the input match should be optimized at the rated RF input power.

Interstage matching can be optimized by changing the value and/or position of the decoupling capacitor on the  $V_{D1}$  supply line. Moving the capacitor closer to the device or reducing the value increases the frequency of resonance with the inductance of the device's wirebonds and leadframe pin.

Output matching is accomplished with a two-stage low-pass network as a compromise between bandwidth and harmonic rejection. Implementation is through chip capacitors mounted along a 30 or 50 $\Omega$  microstrip transmission line. Values and positions are chosen to present a 2 $\Omega$  loadline to the device while conjugating the device output parasitics. The network must also properly terminate the second and third harmonics to optimize efficiency and reduce harmonic output. When low-Q commercial chip capacitors are used for the shunt capacitors, loss can be reduced by mounting two capacitors in parallel to achieve the total value needed.

Loss in circuit traces must also be considered. The output transmission line and the bias supply lines should be at least 0.6 mm in width to accommodate the peak circulating currents which can be as high as 2 amperes. The bias supply line which supplies the output should include an RF choke of at least 8 nH, surface mount solenoid inductors or equivalent length of microstrip lines. Discrete inductors will usually give better efficiency and conserve board space.

The DC blocking capacitor required at the output of the device is best mounted at the 50 $\Omega$  impedance point in the circuit where the RF current is at a minimum and the capacitor loss will have less effect.

### Power Control Using the MC33169

The MC33169 is a dedicated GaAs power amplifier support IC which provides the -4 V required for  $V_{SS}$ , an N-MOS drain switch interface and driver and power supply sequencing. The MC33169 can be used for power control in applications where the amplifier is operated in saturation since the output power in non-linear operation is proportional to  $V_{D2}^2$ . This provides a very linear and repeatable power control transfer function.

This technique can be used open-loop to achieve 20–25 dB dynamic range over process and temperature variation. With careful design and selection of calibration points, this technique can be used for GSM phase II control where 29 dB dynamic range is required, eliminating the need for the complexity and cost of closed-loop control.

The transmit waveform ramping function required for systems such as GSM can be implemented with a simple Sallen and Key filter on the MC33169 control loop. The amplifier is then ramped on as the  $V_{RAMP}$  pin is taken from 0 V to 3 V. To implement the different power steps required for GSM, the  $V_{RAMP}$  pin is ramped between 0 V and the appropriate voltage between 0 V and 3 V for the desired output power.

For closed-loop configurations using the MC33169, MMSF4N01HD N-MOS switch and the MRFIC0917 provide a typical 1 MHz 3 dB loop bandwidth. The STANDBY pin must be enabled (3 V) at least 800  $\mu$ s before the  $V_{RAMP}$  pin goes high and disabled (0 V) at least 20  $\mu$ s before the  $V_{RAMP}$  pin goes low. This STANDBY function allows for the enabling of the MC33169 one burst before the active burst thus reducing power consumption.

### Biasing Considerations

Gate bias is supplied to each stage separately through resistive division of the  $V_{SS}$  voltage. The top of each divider is brought out through pins 12 and 13 ( $V_{G2}$  and  $V_{G1}$  respectively) allowing gate biasing through use of external resistors or positive voltages. This allows setting the quiescent current of each stage separately.

For applications where the amplifier is operated close to saturation, such as GSM and analog cellular, the gate bias can be set with resistors. Variations in process and temperature will not affect amplifier performance significantly in these applications. The values shown in the Figure 1 will set quiescent currents of 100 to 200 mA for the first stage and 600 to 1200 mA for the second stage.

For linear modes of operation, the quiescent current must be more carefully controlled. For these applications, the  $V_G$  pins can be referenced to some tunable voltage which is set at the time of radio manufacturing. Less than 1.0 mA is required in the divider network so a DAC can be used as the voltage source. Typical settings for 3.6 V linear operation are 150 mA  $\pm$ 5% for the first stage, and 750 mA  $\pm$ 5% for the second stage.

### Conclusion

The MRFIC0917 offers the flexibility in matching circuitry and gate biasing required for portable cellular applications. Together with the MC33169 support IC, the device offers an efficient system solution for TDMA applications such as GSM where saturated amplifier operation is used.

### Evaluation Boards

Evaluation boards are available for RF Monolithic Integrated Circuits. For a complete list of currently available boards and ones in development for newly introduced product, please contact your local Motorola Distributor or Sales Office.

# Advance Information

## 3.6 V GSM GaAs Integrated Power Amplifier

The MRFIC0919 is a single supply, RF power amplifier designed for the 2.0 W GSM900 handheld radio. The negative power supply is generated inside the chip using RF rectification, which avoids any spurious signal. A built in priority switch is provided to prevent Drain Voltage being applied on the RF lineup if not properly biased by the Negative Voltage. The device is packaged in the TSSOP-16EP package, with exposed backside pad, which allows excellent electrical and thermal performance through a solderable contact.

- Target 3.6 V Characteristics:
  - RF Input Power: 3.0 dBm
  - RF Output Power: 35.3 dBm Typical
  - Efficiency: 53% Typical
- Single Positive Supply Solution
- Negative Voltage Generator
- Positive Step-up Voltage Generator
- V<sub>SS</sub> Check Switch for Gate-Drain Priority

## APPLICATIONS INFORMATION

### Design Philosophy

The MRFIC0919 is a high performance three stage GaAs IPA (Integrated Power Amplifier) designed for GSM handheld radios (880 to 915 MHz frequency band). With a 3.6 V battery supply, it delivers typically 35.3 dBm of Output Power with 53% Power Added Efficiency.

It features an internal Negative Voltage Generator based on RF rectification of the input carrier after its amplification by a dedicated buffer stage (see Internal Block Diagram). This method eliminates spurs found on the Output signal when using DC/DC converter type negative voltage generators, either on or off chip. The buffer also generates a step-up positive voltage which can be used to drive a N-MOS drain switch.

The RF input power is split internally to the 3 stage RF line-up (Q1,Q2 and Q3) and the Buffer. This arrangement allows separate operation of Voltage Generation and Power Amplification for maximum flexibility.

### External Circuit Considerations

The MRFIC0919 can be tuned by changing the values and/or positions of the appropriate external components (see Figure 1. Reference Circuit). While tuning the RF line-up, it is recommended to apply external negative supply in order to prevent any damage to the power amplifier stages. Poor tuning on the input may not provide enough RF power to operate the negative voltage generator properly.

Input matching is a shunt-C, series-L low-pass structure and should be optimized at the rated RF Input power (e.g., 3.0 dBm). Since the Input line feeds both 1st stage and buffer, Input matching should be iterated with Buffer and Q1 drain matching. Note that a DC blocking capacitor is included on chip.

Buffer drain is supplied and matched through a discrete chip inductor. Its value is tuned to get the maximum output from voltage generator.

The step-up positive voltage available at Pin 1 is both decoupled and maximized by a small shunt capacitor. This positive voltage which is approximately twice the buffer drain voltage can be used to drive a N-MOS drain switch for best performance.

Q1 drain is supplied and matched through a printed microstrip line that could be replaced by a discrete chip inductor as well. Its length (or equivalent inductor value) is tuned by sliding the RF decoupling capacitor along to get the maximum gain on the first stage. Make sure when laying out the PCB to put enough ground pads and vias close to the microstrip lines to help for this fine tuning.

Q2 is supplied through a printed microstrip line that contributes also to the interstage matching in order to provide optimum drive to the final stage. The line length is very small so replacing it with a discrete inductor is not practical.

Q3 drain is feed via a printed line that must handle the high supply current of that stage (2.0 to 3.0 Amp peak) without significant voltage drop. This line can be buried in an inner layer to save PCB space or be a discrete RF choke.

Output matching is accomplished with a two stage low-pass network. Easy implementation is achieved with shunt capacitors mounted along a 30  $\Omega$  microstrip transmission line. Value and position are chosen to reach a load line of 1.8  $\Omega$  while conjugating the device output parasitics. The network must also properly terminate the

second and third harmonic to optimize efficiency and reduce harmonic level. Use of high Q capacitor for the output matching circuit is recommended in order to get the best Output Power and Efficiency performance.

### Biasing Considerations

The internally generated negative voltage is clamped by an external Zener diode in order to eliminate variation linked to Input power or Buffer supply. This negative voltage is used by three independent bias circuits to set the proper quiescent current of all stages. Each bias circuit is equivalent to a current source sinking its value from the bias pin. When the bias pins are grounded, nominal quiescent current and operating point of each RF stage are selected.

Q1 and Buffer share the Bias1 (0.25 mA) while Q2 and Q3 have dedicated Bias2 (0.25 mA) and Bias3 (0.5 mA) respectively. It is also possible to reference those bias pins to higher voltage than Gnd by using a series resistor that drops the equivalent voltage.

If those pins are left open, the corresponding stages are pinched-off. Thus the bias pins can be used as a means to select the MRFIC0919 or MRFIC1819 in a dual band configuration. The MRFIC1819 is the partner device to the MRFIC0919 and is designed for DCS1800/PCS1900 applications.

**Table 2. Pin Function Description**

Pin	Symbol	Description
1	V <sub>P</sub>	Positive voltage output
2	V <sub>D3</sub>	Third stage drain supply
3	RF Out	RF output
4	RF Out	RF output
5	RF Out	RF output
6	Bias3	Third stage bias
7	Bias2	Second stage bias
8	Bias1	Buffer and first stage bias
9	V <sub>SS</sub>	Negative voltage output
10	V <sub>SC</sub>	Negative voltage check
11	V <sub>D2</sub>	Second stage drain supply
12	Gnd	Tied to ground externally
13	V <sub>D1</sub>	First stage drain supply
14	RF In	RF input
15	Gnd	Tied to ground externally
16	V <sub>DB</sub>	Buffer stage drain supply

V<sub>SC</sub> is an open drain internal FET switch which is biased through the negative voltage. Consequently, this pin is high impedance when negative voltage is okay and low impedance (about 40  $\Omega$ ) when negative voltage is missing.

### Operation Procedure

The MRFIC0919 is a standard MESFET GaAs Power Amplifier, presence of a negative voltage to bias the RF line-up is essential in order to avoid any damage to the parts. Due to the fact that the negative voltage is generated through rectification of the RF input signal, a minimum input power

level is needed for correct operation of the demoboard. The following procedure will guaranty safe operation for doing the RF measurements.

Note: make sure that Bias1 (pin 8) is connected to ground or will have equivalent potential for nominal biasing of Buffer stage.

1. Apply RF input power (RF In) >3.0 dBm.
2. Apply  $V_{DB} = 3.0$  to  $5.0$  V.
3. Check that  $V_{SS}$  reaches approximately  $-5.1$  V (settling of the negative voltage).
4. Apply  $V_{D1,2\&3}$  0 to  $5.0$  V.
5. Measure RF output power and relevant parameters.

Proceed in the reverse order to switch off the Power Amplifier.

**Control Considerations**

MRFIC0919 application uses the drain control technique developed for our previous range of GaAs IPAs (refer to application note AN1599). This method relies on the fact that for an RF amplifier operating in saturation mode, the RF output power is proportional to the square of the Amplifier drain voltage:  $P_{out}(Watt)=k*Vd(Volt)*Vd(Volt)$ .

In the proposed application circuit (see figure 2: application circuit), a PMOS FET is used to switch the IPA drain and vary the drain supply voltage from 0 to battery voltage. As the PMOS FET has a non linear behavior, an OpAmp is included in the application. This OpAmp is linearizing the PMOS by sensing its drain output and gives a true linear relationship between the Control voltage and the RF output voltage.

The obtained power control transfer function is so linear and repeatable than it can be used to predict the output power within a dynamic of 25 to 30 dB over frequency and temperature range. This so called "open-loop" arrangement eliminates the need for coupler and detector required for the classical but complex closed-loop control and consequently reduces the Insertion Loss from Power Amplifier to the Antenna.

The following block diagram shows the principle of operation as implemented in the application circuit of Figure 2. The OpAmp is connected as an inverter to compensate the negative gain of the PMOS switch.

**Figure 16. Drain Control through PMOS Switch**

**NOTE:** The positive voltage generated by the Buffer stage can be used to supply the OpAmp and make it possible to drive a NMOS switch as a voltage follower. Doing so, the main advantage is to have a lower  $R_{dson}$  switch and better intrinsic linearity.

The following plot illustrates the "open-loop" performance as far as temperature stability. The measured datas are displayed in a log-scale in order to have a good representation of both the dynamic and the linearity of control. The variation of  $P_{out}$  accross the frequency band are also very small (less than 1.0 dB ripple) and are kept to that small amount when controlling  $P_{out}$  through the Drain voltage.

**Figure 17.  $P_{out}$  versus  $V_D$**

# MRFIC0919

Figure 18. Timing Guide

### Burst mode

Use Figure 18 as a guide line to perform burst mode measurements with the complete application circuit of Figure 2. Notice that the  $V_{SC}$  pin is connected to  $V_{ramp}$  (through a resistor) and act as a pull down when negative voltage is missing so that drain voltage is not applied to the RF line-up.

– Bursting the OpAmp with its Pin 8 (shdn) is not mandatory during a call as the OpAmp current consumption is very small (1.0 to 2.0 mA). This pin is mainly used for the idle mode of the radio. In any case, the wake-up time of the OpAmp is very short.

–  $V_{ramp}$  can be applied soon after Tx EN since the internal negative voltage generator settles in less than 2.0 μs.

– Tx EN signal can be used to switch the input power (using a driver or attenuator) in order to provide higher isolation for on/off burst dynamic.

# 900 MHz GaAs Low Noise Amplifier with Gain Control

Designed primarily for use in 900 MHz wireless communication systems such as GSM, AMPS, and Industrial, Scientific, and Medical (ISM) band applications. The MRFIC0930 is a two-stage low noise amplifier with an integrated step attenuator and is packaged in a low-cost SO-8 package. The MRFIC0930DM is packaged in the smaller Micro-8 package. The attenuator is controlled by a  $V_{gain}$  Pin. The LNA can be turned off during transmit mode to save current by using the Rx Enable Pin. The amplifier can be matched to optimize gain or noise figure with simple off-chip input matching.

- Usable Frequency Range = 800 to 1000 MHz
- 19 dB Typ Gain
- Gain Attenuation = 18 dB (Typ)
- 1.7 dB Typ Noise Figure
- Simple Off-chip Matching for Maximum Gain/Noise Figure Flexibility
- High Reverse Isolation = 41 dB (Typ)
- Low Power Consumption = 24 mW (Typ)
- Single Bias Supply = 2.7 to 4.5 V
- Low Standby Current = 20  $\mu$ A (Typ)
- Low Cost Surface Mount Plastic Package

## APPLICATIONS INFORMATION

### Design Philosophy

The MRFIC0954 has three operating states, enable, standby, and disable. These states are controlled by the truth table shown in Table 3. The device is fully operational during the enable state and the bias level can be selected. A high bias current for CDMA or a lower bias current for Analog (or CDMA at lower powers) can be selected via the FM/CDMA pin. In the high current CDMA mode, the quiescent current is increased to maximize the linearity of the device. In the lower current bias, the quiescent current is optimized for efficiency in the Analog mode. This lower bias point is also useful in lower power CDMA operation. The standby mode can be used to reduce current consumption during Voice Activity Factoring. In the standby mode, the LO buffer remains on to prevent VCO pulling and the bandgap reference bias circuit remains on to assure rapid device turn on. Current consumption in standby mode is 10 mA typical. The disable mode is used to turn the MRFIC0954 completely off. Leakage current in this mode is only a few microamps.

The mixer is a double-balanced “Gilbert-cell” design with a balanced LO buffer amplifier. The input and output of the mixer are differential. However, the linearity is high enough to tie one output to  $V_{CC}$  and use the other as a single-ended output. Used this way it provides around 7.0 dB of gain and typically draws 20 mA quiescent current in CDMA mode and 16 mA in Analog Mode. An external filter is required between the mixer and RF AGC amplifier to reduce RX band noise.

Figure 1 shows the applications circuit for the MRFIC0954. In this circuit, the IF ports of the mixer have been matched to 50  $\Omega$  for testing purposes. In the actual application, the differential IF ports of the mixer would be impedance matched to an IF SAW filter. The differential impedance of the mixer IF ports is 1600  $\Omega$ . The RF output of the mixer is configured as a single ended output. DC current to the open collector output of the mixer is provided by inductor, L6 (6.8 nH). Inductor L6 is also part of the matching circuit with C13 (1.6 pF), C14 (1.3 pF) and C15 (100 p).

The RF AGC amplifier is a single-ended cascode design employing the standard “current steering” method of gain control. It’s ground is brought out through pin number 15 so inductance can be added to degenerate the gain for a lower noise floor. With 2.0 to 3.0 nH of external inductance, the maximum gain is around 13 dB. It typically draws 9.0 mA quiescent current in CDMA mode and 3.0 mA in Analog mode. The RF  $V_{ctrl}$  signal is buffered with an on-chip OpAmp then preconditioned with temperature compensation and dB/V linearization before being applied to the RF AGC amplifier.

Inductor L3 (6.8 nH) and capacitor C6 (100 pF) are for the interstage match between the RF AGC and the exciter amplifier.

The exciter amplifier is a simple common emitter design. It is grounded directly to the exposed pad which results in 12 dB of gain. It typically draws 24 mA bias current in CDMA mode and 8.0 mA in Analog mode. Inductor L4 (6.8 nH),

capacitor C7 (4.3 pF), and C9 (100 pF) provide the output matching. L4 also provides a DC current path for the open collector output.

### Noise Power Considerations

In CDMA systems, the handset is required to dynamically adjust its output power to specific levels. This requires a dynamic range of as much as 90 dB from the transmitter. Another key performance specification in CDMA systems is the output noise power, both in band and out of band. Noise power specifications has caused the noise figure of the transmitter to become an important system consideration. The cascaded noise figure of the transmitter can be analyzed with the same equation used in receiver analysis. The only difference is the noise source is from the transmitter (modulator) instead of the atmosphere.

$$NF_{\text{cascaded}} = NF_1 + \frac{NF_2 - 1}{G_1} + \frac{NF_3 - 1}{G_1 G_2}$$

This equation above shows that the cascaded noise figure is better if the gain is higher and the noise figure is lower for the stages close to the noise source. For this reason, it is advantageous to implement some of the gain control of a CDMA transmitter in the RF section. The MRFIC0954 integrates a RF AGC amplifier after the upmixer to improve the overall noise figure of the transmitter.

If better noise figure from the mixer is required, the mixer RF output can be operated differentially with the addition of a balun. Operating the mixer differentially will provide some noise cancellation and reduce the noise figure by 5.0 dB. Shown below is a lumped element balun that is effective in the cellular transmit band of 824 to 849 MHz.

## The MRFIC Line GPS GaAs Low Noise Amplifier

The MRFIC1501 is a low cost yet high performance two-stage, low-noise amplifier designed primarily for use in Global Positioning Satellite System (GPS) and other L-band satellite receivers. The broadband nature of the design makes the device applicable to a variety of L-band applications where high performance at reasonable current and cost are required. Supply current is minimized through a current sharing DC cascode circuit configuration. Supply voltage can be applied to either the  $V_{DD}$  pin or the RF output pin for remote antenna applications. The integrated circuit requires minimal off-chip matching while allowing for maximum flexibility in optimizing gain and noise figure. An ENABLE pin is provided to allow for a reduced supply current standby mode. The design employs Motorola's low cost planar self-aligned MESFET process to assure repeatable characteristics at minimal cost.

- Usable Frequency Range = 1 to 2 GHz
- 18 dB Typ Gain at  $V_{DD}$  = 5 Volts
- 1.1 dB Typ Noise Figure at  $V_{DD}$  = 5 Volts
- Simple Off-chip Matching for Maximum Gain/Noise Figure Flexibility
- Single Bias Supply = 3 to 5 Volts
- Low Power Consumption = 30 mW (Typ) at 5 Volts
- Low Cost Surface Mount Plastic Package
- Order MRFIC1501R2 for Tape and Reel.  
R2 Suffix = 2,500 Units per 12 mm, 13 inch Reel.
- Device Marking = M1501

## APPLICATIONS INFORMATION

### DESIGN CONSIDERATIONS

The circuit configuration employs a DC cascode arrangement which allows current sharing between two FETs. This gives excellent noise figure at reduced supply current. Since GPS applications often require the downconverter to be remotely mounted at the antenna, the output is DC coupled so that the drain voltage can be supplied through the coax feed. The  $V_{DD}$  pin can actually supply other components in the equipment at less than 20 mA of current. On-chip bias circuitry tracks changes in device threshold voltage and temperature and is externally controlled through the ENABLE pin. This feature allows for a low current standby mode or for gain reduction. Refer to Figure 9 for control characteristics.

### CIRCUIT CONSIDERATIONS

As shown in Figure 1, impedance matching of the MRFIC1501 is quite simple. Through use of an on-chip

source inductor in the first stage,  $\Gamma_{opt}$  and  $\Gamma_{in}^*$  are approximately equal. A single inductor at the input will give good input match and noise figure. This inductor can be implemented with a high impedance microstrip line or a chip inductor.

As with all RF active circuit designs, bypassing the supply pin is recommended. Layout and ground via location is important. Vias should be located as close as possible to ground pins and the ground side of off-chip components.

### EVALUATION BOARDS

Evaluation boards are available for RF Monolithic Integrated Circuits by adding a "TF" to the device type. For a complete list of currently available boards and ones in development for newly introduced products, please consult your local Motorola Distributor or Sales Office.

**MOTOROLA**

# 1.9 GHz GaAs Low Noise Amplifier

Designed primarily for use in wireless Personal Communication Systems (PCS) applications such as Digital European Cordless Telephone (DECT), Japan's Personal Handy System (PHS) and the emerging North American systems as a preamp for discrete or integrated downmixers. The MRFIC1808DM is a two-stage low noise amplifier in a low-cost Micro-8 package. The amplifier can be matched to optimize gain or noise figure with simple off-chip input matching. The design employs a novel stacked MESFET design which reuses bias current for the highest gain at minimal current. A CMOS compatible Rx Enable pin allows for very low standby current while the system is in transmit mode.

- Usable Frequency Range = 1.7 to 2.1 GHz
- 18 dB Typ Gain
- 1.6 dB Typ Noise Figure
- Simple Off-chip Matching for Maximum Gain/Noise Figure Flexibility
- High Reverse Isolation = 32 dB (Typ)
- Single Bias Supply = 2.7 to 4.5 V
- Low Standby Current = 8  $\mu$ A (Typ)
- Low Cost Surface Mount Plastic Package
- Device Marking = M1808

## MRFIC1808

### 1.9 GHz GaAs LOW NOISE AMPLIFIER

#### SEMICONDUCTOR TECHNICAL DATA

(Scale 2:1)

**DM SUFFIX**  
PLASTIC PACKAGE  
CASE 846A  
(Micro-8, Tape & Reel Only)

#### Simplified Block Diagram

This device contains 5 active transistors.

#### PIN CONNECTIONS

#### ORDERING INFORMATION

Device	Operating Temp Range	Package
MRFIC1808DMR2	T <sub>A</sub> = -30 to 85°C	Micro-8

# MRFIC1808

## MAXIMUM RATINGS ( $T_A = 25^\circ\text{C}$ , unless otherwise noted)

Rating	Symbol	Value	Unit
Supply Voltage	$V_{DD}$	5.5	Vdc
RF Input Power	$P_{RF}$	3.0	dBm
Enable Voltage	Rx Enable	5.5	Vdc
Storage Temperature Range	$T_{stg}$	-65 to 150	$^\circ\text{C}$
Operating Ambient Temperature	$T_A$	-30 to 85	$^\circ\text{C}$

- NOTES:** 1. Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Recommended Operating Conditions or Electrical Characteristics tables.  
 2. Meets Human Body Model (HBM)  $\leq 500$  V and Machine Model (MM)  $\leq 200$  V.  
 3. ESD data available upon request.

## RECOMMENDED OPERATING CONDITIONS

Parameter	Symbol	Min	Typ	Max	Unit
RF Frequency	$f_{RF}$	1.7	-	2.1	GHz
Supply Voltage	$V_{DD}$	2.7	-	4.5	Vdc
Rx Enable Voltage, ON	Rx Enable	2.7	-	$V_{DD}$	Vdc
Rx Enable Voltage, OFF	Rx Enable	0	-	0.2	Vdc

## ELECTRICAL CHARACTERISTICS ( $V_{DD} = 3.0$ V, $T_A = 25^\circ\text{C}$ , $RF = -30$ dBm @ 1.9 GHz, Rx Enable = 3.0 V, unless otherwise noted. Tested in Circuit Shown in Figure 1)

Characteristic	Symbol	Min	Typ	Max	Unit
RF Gain	-	16	18	-	dB
SSB Noise Figure	-	-	1.6	-	dB
RF Output 3rd Order Intercept Point	-	-	13	-	dBm
Output 1 dB Gain Compression	-	-3.0	1.0	-	dBm
Reverse Isolation ( $s_{12}$ )	-	-	-34	-	dB
Input Return Loss	-	-	-12	-	dB
Output Return Loss	-	-	-15	-	dB
Supply Current, Rx Mode	-	-	5.0	7.5	mA
Supply Current, Standby Mode (Rx Enable = 0 V)	-	-	-	50	$\mu\text{A}$

## The MRFIC Line 1.9 GHz GaAs Upconverter

Designed primarily for use in wireless Personal Communication Systems (PCS) applications such as Digital European Cordless Telephone (DECT), Japan's Personal Handy System (PHS) and the emerging North American systems. The MRFIC1813 is also applicable to 2.4 GHz ISM equipment. The device combines a balanced upmixer and a transmit exciter amplifier in a low-cost TSSOP-16 package. Minimal off-chip matching is required while allowing for maximum flexibility and efficiency. The mixer is optimized for low-side injection and provides more than 12 dB of conversion gain with over 0 dBm output at 1 dB gain compression. Image filtering is implemented off-chip to allow maximum flexibility. A CMOS compatible ENABLE pin allows standby operation where the current drain is less than 250  $\mu$ A.

Together with other devices from the MRFIC180X or the MRFIC240X series, this GaAs IC family offers the complete transmit and receive functions, less LO and filters, needed for a typical 1.8 GHz cordless telephone or 2.4 GHz ISM band equipment.

- Usable Frequency Range = 1.7 to 2.5 GHz
- 15 dB Typ IF to RF Conversion Gain
- 3 dBm Power Output Typ, 0 dBm Minimum at 1 dB Gain Compression
- Simple Off-chip Matching for Maximum Flexibility
- Low Power Consumption = 75 mW (Typ)
- Single Bias Supply = 2.7 to 4.5 Volts
- Low LO Power Requirement = - 5 dBm (Typ)
- Low Cost Surface Mount Plastic Package
- Order MRFIC1813R2 for Tape and Reel.  
R2 Suffix = 2,500 Units per 16 mm, 13 inch Reel.
- Device Marking = M1813

# MRFIC1813

## APPLICATIONS INFORMATION

### DESIGN CONSIDERATIONS

The MRFIC1813 combines a single-balanced MESFET mixer with an exciter amplifier. It is usable for transmit frequencies from 1.7 to 2.5 GHz and IF frequencies from 70 to 350 MHz. The design is optimized for low-side local oscillator injection in heterodyne transmit applications.

Minimal off-chip matching is required while allowing for flexibility and performance optimization. An active balun is employed at the IF port which gives good balance down to at least 70 MHz. A passive splitter is used at the LO input to complete the single-balanced configuration.

### CIRCUIT CONSIDERATIONS

Figure 1 shows the application circuit used to gather the data presented in the characterization curves. As shown in Table 1, the IF port impedance is very high. Three hundred ohms was chosen for R1 to shunt the IF port as a compromise of gain and bandwidth. A 50 Ω resistor can be used and L1 and C5 eliminated to provide a broadband match. The

conversion gain is reduced to about 8 dB. Microstrip inductors T1 and T2 combine with inductance internal to the device to form RF chokes. Some tuning of the RF output can be achieved with T1.

As with all RF devices, circuit layout is important. Controlled impedance lines should be used for all RF and IF interconnects. As shown in Figure 1, power supply bypassing should be used to avoid device instability. Ground vias should be included near all ground connections indicated in the schematic. Off-chip components should be mounted as close to the IC leads as possible.

### EVALUATION BOARDS

Evaluation boards are available for RF Monolithic Integrated Circuits by adding a "TF" to the device type. For a complete list of currently available boards and one in development for newly introduced products, please contact your local Motorola Distributor or Sales Office.

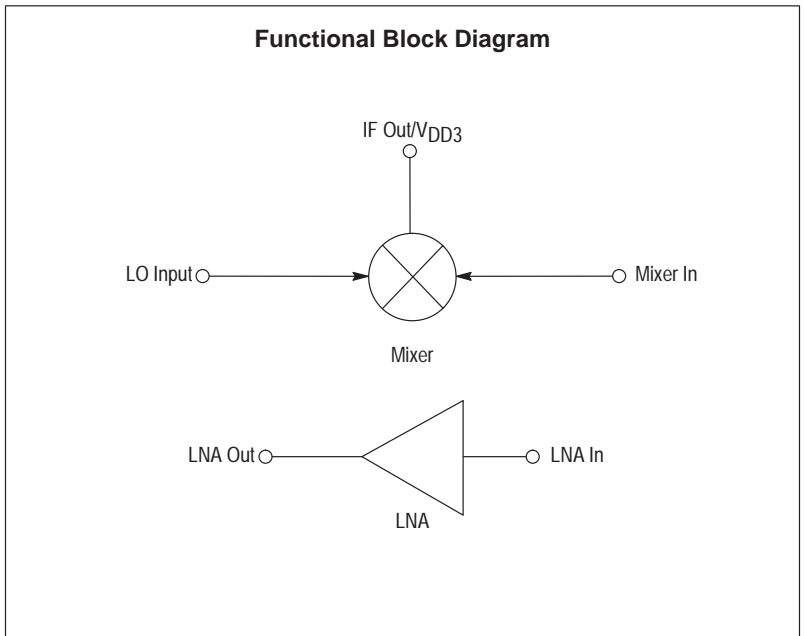

# 1.9 GHz GaAs Downconverter

Designed primarily for use in wireless Personal Communication Systems (PCS) applications such as Digital European Cordless Telephone (DECT), Japan's Personal Handy System (PHS), and the emerging North American systems. The MRFIC1814 includes a low noise amplifier and downmixer in a low-cost TSSOP-16 package. The integrated circuit requires minimal off-chip matching while allowing for the maximum in flexibility and efficiency. The mixer is optimized for low-side injection and offers reasonable intercept point as well as high efficiency with 8.0 dB of conversion gain. Image filtering is implemented off-chip to allow maximum flexibility. CMOS compatible ENABLE pins allow standby operation where the current drain is less than 0.1 mA.

Together with the rest of the MRFIC18XX series, this GaAs IC family offers the complete transmit and receive functions, less LO and filters, needed for a typical 1.8 GHz cordless telephone.

- Usable Frequency Range = 1.8 to 2.0 GHz
- 17 dB Typ Gain, 2.5 dB Typ Noise Figure LNA
- 8.0 dB Typ Gain, 10 dB Typ Noise Figure Mixer
- -5.5 dBm Typ Mixer Input Intercept Point
- Simple LO/IF Off-chip Matching for Maximum Flexibility
- Low Power Consumption = 39 mW (Typ)
- Single Bias Supply = 2.7 to 4.5 V
- Low LO Power Requirement = -5.0 dBm (Typ)
- Low Cost Surface Mount Plastic Package

**NOT RECOMMENDED FOR NEW DESIGN  
DEVICE TO BE PHASED OUT.  
No replacement available.**

# 1800 MHz GaAs Integrated Power Amplifier

Designed specifically for application in Pan European digital 1.0 watt DCS1800/PCS1900 handheld radios, the MRFIC1817 is specified for 32 dBm output power with power gain over 27 dB from a 3.6 V supply. To achieve this superior performance, Motorola's planar GaAs MESFET process is employed. The device is packaged in the PFP-16 Power Flat Package which gives excellent thermal and electrical performance through a solderable backside contact while allowing the convenience and cost benefits of reflow soldering.

- Minimum Output Power Capabilities
  - 32 dBm @ 3.6 V
  - 30 dBm @ 3.0 V
- Typical Volt Characteristics
  - RF Input Power = 5.0 dBm
  - RF Output Power = 33.5 dBm
  - Typical PAE = 42%
- Low Current required from Negative Supply -2.0 mA max
- Guaranteed Stability and Ruggedness
- Device Marking = M1817

### MAXIMUM RATINGS ( $T_A = 25^\circ\text{C}$ , $Z_O = 50 \Omega$ , unless otherwise noted)

Rating	Symbol	Value	Unit
DC Positive Supply Voltage	$V_{D1, 2, 3}$	6.0	Vdc
DC Negative Supply Voltage	$V_{SS}$	-5.0	Vdc
RF Input Power	$P_{in}$	10	dBm
RF Output Power	$P_{out}$	35	dBm
Operating Case Temperature Range	$T_C$	-35 to 85	$^\circ\text{C}$
Storage Temperature Range	$T_{stg}$	-55 to 150	$^\circ\text{C}$
Thermal Resistance, Junction to Case	$R_{\theta JC}$	10	$^\circ\text{C/W}$

**NOTES:** 1. ESD data available upon request.  
 2. Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics or Recommended Operating Conditions tables.

## APPLICATIONS INFORMATION

### Design Philosophy

The MRFIC1817 is a 3-stage integrated power amplifier designed for use in cellular phones, especially for those used in DCS1800 (PCN) 3.6 V operation. With matching circuit modifications, it is also applicable for use in DCS1900 (PCS) equipment. Due to the fact that the input, output and some of the interstage matching is accomplished off-chip, the device can be tuned to operate anywhere within the 1500 to 2000 MHz frequency range. Typical performance at different battery voltages is:

- 33.5 dBm @ 3.6 V
- 32.0 dBm @ 3 V

This capability makes the MRFIC1817 suitable for portable cellular applications such as:

- 3 V and 3.6 V DCS1800 Class I and II
- 3 V and 3.6 V PCS tag5

### RF Circuit Considerations

The MRFIC1817 can be tuned by changing the values and/or positions of the appropriate external components. Refer to Figure 2, a typical DCS1800 Class I applications circuit. The input match is a shunt-L, series-C, high-pass structure and can be retuned as desired with the only limitation being the on-chip 6 pF blocking capacitor. For saturated applications such as DCS1800 and PCS1900, the input match should be optimized at the rated RF input power. Interstage matching can be optimized by changing the value and/or position of the decoupling capacitor on the  $V_{D1}$  and  $V_{D2}$  supply lines. Moving the capacitor closer to the device or reducing the value increases the frequency of resonance with the inductance of the device's wirebonds and leadframe pin. Output matching is accomplished with a low-pass network as a compromise between bandwidth and harmonic rejection. Implementation is through high Q capacitors mounted along a 50  $\Omega$  microstrip transmission line. Values and positions are chosen to present a 2 W loadline to the device while conjugating the device output parasitics. The network must also properly terminate the second and third harmonics to optimize efficiency and reduce harmonic output. All components used in this application are low-Q commercial chip capacitors, except for the output load line. Loss in circuit traces must also be considered. The output transmission line and the bias supply lines should be at least 0.6 mm in width to accommodate the peak circulating currents which can be as high as 2 amperes under worst case conditions. The bias supply line which supplies the output should include an RF choke of at least 18 nH, surface mount solenoid inductors or quarter wave microstrip lines. Discrete inductors will usually give better efficiency and conserve board space.

### Biasing Considerations

Gate bias lines are tied together and connected to the  $V_{SS}$  voltage, allowing gate biasing through use of external resistors or positive voltages. This allows setting the quiescent current of all stage in the same time while saving some board space. For applications where the amplifier is operated close to saturation, such as with TDMA amplifiers, the gate bias can be set with resistors. Variations in process

and temperature will not affect amplifier performance significantly in these applications. The values shown in the Figure 1 will set quiescent currents of 20 to 40 mA for the first stage, 150 to 300 mA for the second stage, and 400 to 800 mA for the final stage. For linear modes of operation which are required for CDMA amplifiers, the quiescent current must be more carefully controlled. For these applications, the  $V_G$  pins can be referenced to some tunable voltage which is set at the time of radio manufacturing. Less than 1 mA is required in the divider network so a DAC can be used as the voltage source.

### Power Control Using the MC33169

The MC33169 is a dedicated GaAs power amplifier support IC which provides the  $-4$  V required for  $V_{SS}$ , an N-MOS drain switch interface and driver and power supply sequencing. The MC33169 can be used for power control in applications where the amplifier is operated in saturation since the output power in non-linear operation is proportional to  $V_{D2}$ . This provides a very linear and repeatable power control transfer function. This technique can be used open loop to achieve 40–45 dB dynamic range over process and temperature variation. With careful design and selection of calibration points, this technique can be used for DCS1800 control where 30 dB dynamic range is required, eliminating the need for the complexity and cost of closed-loop control. The transmit waveform ramping function required for systems such as DCS1800 can be implemented with a simple Sallen and Key filter on the MC33169 control loop. The amplifier is then ramped on as the  $V_{RAMP}$  pin is taken from 0 V to 3 V. To implement the different power steps required for DCS1800, the  $V_{RAMP}$  pin is ramped between 0 V and the appropriate voltage between 0 V and 3 V for the desired output power. For closed-loop configurations using the MC33169, MMSF4N01HD N-MOS switch and the MRFIC1817 provide a typical 1 MHz 3 dB loop bandwidth. The STANDBY pin must be enabled (3 V) at least 800  $\mu$ s before the  $V_{RAMP}$  pin goes high and disabled (0 V) at least 20 ms before the  $V_{RAMP}$  pin goes low. This STANDBY function allows for the enabling of the MC33169 one burst before the active burst thus reducing power consumption.

### Conclusion

The MRFIC1817 offers the flexibility in matching circuitry and gate biasing required for portable cellular applications. Together with the MC33169 support IC, the device offers an efficient system solution for TDMA applications such as DCS1800 where saturated amplifier operation is used.

For more information about the power control using the MC33169, refer to application note AN1599, "Power Control with the MRFIC0913 GaAs Integrated Power Amplifier and MC33169 Support IC."

### Evaluation Boards

Two versions of the MRFIC1817 evaluation board are available. Order MRFIC1817DCSTF for the 1.8 GHz version and order MRFIC1817PCSTF for the 1.9 GHz version. For a complete list of currently available boards and ones in development for newly introduced product, please contact your local Motorola Distributor or Sales Office.

## APPLICATIONS INFORMATION

### Design Philosophy

The MRFIC1818 is a 3-stage Integrated Power Amplifier designed for use in cellular phones, especially for those used in DCS1800 (PCN) 4.8 V operation. With matching circuit modifications, it is also applicable for use in DCS1900 (PCS) equipment. Due to the fact that the input, output and some of the interstage matching is accomplished off chip, the device can be tuned to operate anywhere within the 1500 to 2000 MHz frequency range. Typical performance at different battery voltages is:

- 36 dBm @ 6.0 V
- 34.5 dBm @ 4.8 V
- 32.0 dBm @ 3.6 V

This capability makes the MRFIC1818 suitable for portable cellular applications such as:

- 6V and 4.8 V DCS1800 Class I
- 6V and 4.8 V PCS tag5
- 3.6 V DCS1800 Class II

### RF Circuit Considerations

The MRFIC1818 can be tuned by changing the values and/or positions of the appropriate external components. Refer to Figure 2, a typical DCS1800 Class I applications circuit. The input match is a shunt-L, series-C, High-pass structure and can be retuned as desired with the only limitation being the on-chip 6.0 pF blocking capacitor. For saturated applications such as DCS1800 and DCS1900, the input match should be optimized at the rated RF input power. Interstage matching can be optimized by changing the value and/or position of the decoupling capacitor on the  $V_{D1}$  and  $V_{D2}$  supply lines. Moving the capacitor closer to the device or reducing the value increases the frequency of resonance with the inductance of the device's wirebonds and leadframe pin. Output matching is accomplished with a one-stage low-pass network as a compromise between bandwidth and harmonic rejection. Implementation is through chip capacitors mounted along a 30 or 50  $\Omega$  microstrip transmission line. Values and positions are chosen to present a 2.5 W loadline to the device while conjugating the device output parasitics. The network must also properly terminate the second and third harmonics to optimize efficiency and reduce harmonic output. Low-Q commercial chip capacitors are used for the shunt capacitors, as shown in Figure 2. Loss in circuit traces must also be considered. The output transmission line and the bias supply lines should be at least 0.6 mm in width to accommodate the peak circulating currents which can be as high as 2.0 amperes under worst case conditions. The bias supply line which supplies the output should include an RF choke of at least 18 nH, surface mount solenoid inductors or quarter wave microstrip lines. Discrete inductors will usually give better efficiency and conserve board space. The dc blocking capacitor required at the output of the device is best mounted at the 50  $\Omega$  impedance point in the circuit where the RF current is at a minimum and the capacitor loss will have less effect.

### Biasing Considerations

Gate bias lines are tied together and connected to the  $V_{SS}$  voltage, allowing gate biasing through use of external resistors or positive voltages. This allows setting the quiescent current of all stage in the same time while saving some board space. For applications where the amplifier is

operated close to saturation, such as TDMA amplifiers, the gate bias can be set with resistors. Variations in process and temperature will not affect amplifier performance significantly in these applications. The values shown in the Figure 1 will set quiescent currents of 20 to 40 mA for the first stage, 150 to 300 for the second stage and 400 to 800 mA for the final stage. For linear modes of operation which are required for CDMA amplifiers, the quiescent current must be more carefully controlled. For these applications, the  $V_G$  pins can be referenced to some tunable voltage which is set at the time of radio manufacturing. Less than 1.0 mA is required in the divider network so a DAC can be used as the voltage source.

### Power Control Using the MC33169

The MC33169 is a dedicated GaAs power amplifier support IC which provides the -4.0 V required for  $V_{SS}$ , an N-MOS drain switch interface and driver and power supply sequencing. The MC33169 can be used for power control in applications where the amplifier is operated in saturation since the output power in non-linear operation is proportional to  $V_{D2}$ . This provides a very linear and repeatable power control transfer function. This technique can be used open loop to achieve 40 to 45 dB dynamic range over process and temperature variation. With careful design and selection of calibration points, this technique can be used for DCS1800 control where 30 dB dynamic range is required, eliminating the need for the complexity and cost of closed-loop control. The transmit waveform ramping function required for systems such as DCS1800 can be implemented with a simple Sallen and Key filter on the MC33169 control loop. The amplifier is then ramped on as the  $V_{Ramp}$  pin is taken from 0 V to 3.0 V. To implement the different power steps required for DCS1800, the  $V_{Ramp}$  pin is ramped between 0 V and the appropriate voltage between 0 V and 3.0 V for the desired output power. For closed-loop configurations using the MC33169, MMSF4N01HD N-MOS switch and the MRFIC1818 provide a typical 1.0 MHz 3.0 dB loop bandwidth. The STANDBY pin must be enabled (3.0 V) at least 800  $\mu$ s before the  $V_{Ramp}$  pin goes high and disabled (0 V) at least 20  $\mu$ s before the  $V_{Ramp}$  pin goes low. This STANDBY function allows for the enabling of the MC33169 one burst before the active burst thus reducing power consumption.

### Conclusion

The MRFIC1818 offers the flexibility in matching circuitry and gate biasing required for portable cellular applications. Together with the MC33169 support IC, the device offers an efficient system solution for TDMA applications such as DCS1800 where saturated amplifier operation is used.

For more information about the power control using the MC33169, refer to application note AN1599, "Power Control with the MRFIC0913 GaAs Integrated Power Amplifier and MC33169 Support IC."

### Evaluation Boards

Two versions of the MRFIC1818 evaluation board are available. Order MRFIC1818DCSTF for the 1.8 GHz version and order MRFIC1818PCSTF for the 1.9 GHz version. For a complete list of currently available boards and ones in development for newly introduced product, please contact your local Motorola Distributor or Sales Office.

# Advance Information

## 3.6 V 1800 MHz GaAs Integrated Power Amplifier

The MRFIC1819 is a single supply, RF power amplifier designed for the 1W DCS1800/PCS1900 handheld radio. The negative power supply is generated inside the chip using RF rectification, which avoids any spurious signal. A built in priority switch is provided to prevent Drain Voltage being applied on the RF lineup if not properly biased by the Negative Voltage. The device is packaged in the TSSOP-16EP package, with exposed backside pad, which allows excellent electrical and thermal performance through a solderable contact.

- Target 3.6 V Characteristics:
  - RF Input Power: 6.0 dBm
  - RF Output Power: 33 dBm Typical
  - Efficiency: 41% Typical
- Single Positive Supply Solution
- Negative Voltage Generator
- Positive Step-Up Voltage Generator
- V<sub>SS</sub> Check Switch for Gate-Drain Priority

## APPLICATIONS INFORMATION

### Design Philosophy

The MRFIC1819 is a high performance three stage GaAs IPA (Integrated Power Amplifier) designed for DCS/PCS handheld radios (1710–1785 MHz DCS frequency band, 1850–1910 MHz PCS frequency band). With a 3.6 V battery supply, it delivers typically 33 dBm of Output Power with 41% Power Added Efficiency.

It features an internal Negative Voltage Generator based on RF rectification of the input carrier after its amplification by two dedicated buffer stages (see Internal Block Diagram). This method eliminates spurs found on the Output signal when using dc/dc converter type negative voltage generators, either on or off chip. The buffer also generates a step-up positive voltage which can be used to drive a N–MOS drain switch.

The RF input power is split **externally** (different from MRFIC0919) to the 3 stage RF line-up (Q1, Q2 and Q3) and the Buffer amplifier (Q0, QB). This arrangement allows separate operation of Voltage Generation and Power Amplification for maximum flexibility.

### External Circuit Considerations

The MRFIC1819 can be tuned by changing the values and/or positions of the appropriate external components (see Figure 1: Reference Circuit). While tuning the RF line-up, it is recommended to apply external negative supply in order to prevent any damage to the power amplifier stages. Poor tuning on the input may not provide enough RF power to operate the negative voltage generator properly.

Input matching is a shunt–L, series–L high-pass structure and should be optimized at the rated RF Input power (e.g. 6.0 dBm). However, broadband matching is easier with a parallel 680  $\Omega$  resistor. This part can be removed to get operation to a lower input power (e.g. 5.0 dBm). Since the Input line feeds both 1st stage and buffer, Input matching should be iterated with Buffer and Q1 drain matching. Note that a dc blocking capacitor is included on chip.

RF input signal is fed to buffer amplifier using C12 capacitor (Figure 1). The value of this capacitor determines the power split between RF line-up and buffer amplifier. C12 has been tuned to get the best trade-off between RF gain and negative voltage on Pin 9.

First stage buffer amplifier is tuned with a short 80  $\Omega$  microstrip line which may be replaced by a chip inductor (T4 on Figure 1). Second stage buffer amplifier is supplied and matched through a discrete chip inductor. Those two elements are tuned to get the maximum output from voltage generator. The overall typical buffer current is about 50 mA; however, the negative generator needs a settling time of 2.0  $\mu$ sec (see burst mode paragraph). During this transient period of time, both stages are biased to IDSS which is about 200 mA each.

The step-up positive voltage available at Pin 1 is both decoupled and maximised by a small shunt capacitor. This positive voltage which is approximately twice the buffer drain voltage can be used to drive a NMOS drain switch for best performances.

Q1 drain is supplied and matched through a printed microstrip line that could be replaced by a discrete chip inductor as well. Its length (or equivalent inductor value) is tuned by sliding the RF decoupling capacitor along to get the maximum gain on the first stage.

Q2 is supplied through a printed microstrip line that contributes also to the interstage matching in order to provide optimum drive to the final stage.

The line length for Q1 and Q2 is small, so replacing it with a discrete inductor is not practical.

Q3 drain is fed via a printed line that must handle the high supply current of that stage (2.0 Amp peak) without significant voltage drop. This line can be buried in an inner layer to save PCB space or be a discrete RF choke.

Output matching is accomplished with a two stages low-pass network. Easy implementation is achieved with shunt capacitors mounted along a 2.0 mm 30  $\Omega$  microstrip transmission line. Value and position are chosen to reach a load line of 5.5  $\Omega$  while conjugating the device output parasitics. The network must also properly terminate the second and third harmonic to optimize efficiency and reduce harmonic level. Use of high Q capacitor for the first output matching capacitor circuit is recommended in order to get the best Output Power and Efficiency performance.

NOTE: The choice of output matching capacitors type and supplier will affect H2 and H3 level and efficiency, because of serie resonant frequency.

### Biasing Considerations

The internally generated negative voltage is clamped by an external Zener diode in order to eliminate variation linked to Input power or Buffer supply. This negative voltage is used by three independent bias circuits to set the proper quiescent current of all stages. Each bias circuitry is equivalent to a current source sinking its value from the bias pin. When the bias pins are set to 3.0 V, nominal quiescent current and operating point of each RF stage are selected.

Q1 and Buffer share the Bias1 (0.25 mA) while Q2 and Q3 have dedicated Bias2 (0.25 mA) and Bias3 (0.5 mA) respectively. It is also possible to reference those bias pins to Gnd by changing series resistors R1, R2, R3 (Fig. 1) that drops the 3.0 V.

If those pins are left opened, the corresponding stages are pinched-off. Thus the bias pins can be used as a mean to select the MRFIC1819 or the MRFIC0919 in a dual band configuration. The MRFIC0919 is the partner device to the MRFIC1819 and is designed for GSM900 applications.

Table 2. Pin Function Description

Pin	Symbol	Description
1	V <sub>P</sub>	Positive voltage output
2	V <sub>D3</sub>	Third stage drain supply
3	RF Out	RF output
4	RF Out	RF output
5	RF Out	RF output
6	Bias3	Third stage bias
7	Bias2	Second stage bias
8	Bias1	Buffer and first stage bias
9	V <sub>SS</sub>	Negative voltage output
10	V <sub>SC</sub>	Negative voltage check
11	V <sub>D2</sub>	Second stage drain supply
12	V <sub>D1</sub>	First stage drain supply
13	RF In	RF input
14	In Buf	Buffer RF input
15	V <sub>D0</sub>	First buffer stage drain supply
16	V <sub>DB</sub>	Buffer stage drain supply

V<sub>sc</sub> is an open drain internal FET switch which is biased through the negative voltage. Consequently, this pin is high impedance when negative voltage is okay and low impedance (about 40 Ω) when negative voltage is missing.

**Operation Procedure**

The MRFIC1819 is a standard MESFET GaAs Power Amplifier, presence of a negative voltage to bias the RF line-up is essential in order to avoid any damage to the parts. Due to the fact that the negative voltage is generated through rectification of the RF input signal, a minimum input power level is needed for correct operation of the demoboard. The following procedure will guaranty safe operation for doing the RF measurements.

Note: make sure that Bias1 (Pin 8 of demoboard Figure 2) is connected 3.0 V or will have equivalent potential for nominal biasing of Buffer stage.

6. Apply RF input power (RF In) > 6.0 dBm.
7. Apply V<sub>DB</sub> = 3.0 to 5.0 V.
8. Check that V<sub>SS</sub> reaches approximately -5.1 V (settling of the negative voltage) (Pin 9).
9. Apply V<sub>D1,2&3</sub>=0 to 5.0 V.
10. Measure RF output power and relevant parameters.

Proceed in the reverse order to switch off the Power Amplifier.

**Control Considerations**

MRFIC01819 application uses the drain control technique developed for our previous range of GaAs IPAs (refer to application note AN1599). This method relies on the fact that

for an RF amplifier operating in saturation mode, the RF output power is proportional to the square of the Amplifier drain voltage:  $P_{out}(Watt)=k \cdot V_d(Volt) \cdot V_d(Volt)$ .

In the proposed application circuit (see Figure 2: application circuit), a PMOS FET is used to switch the IPA drain and vary the drain supply voltage from 0 to battery voltage. As the PMOS FET has a non linear behavior, an OpAmp is included in the application. This OpAmp is linearizing the PMOS by sensing its drain output and gives a true linear relationship between the Control voltage and the RF output voltage.

The obtained power control transfer function is so linear and repeatable than it can be used to predict the output power within a dynamic of 25 to 30 dB over frequency and temperature range. This so called “open-loop” arrangement eliminates the need for coupler and detector required for the classical but complex closed-loop control and consequently reduces the Insertion Loss from Power Amplifier to the Antenna.

The following block diagram shows the principle of operation as implemented in the application circuit of Figure 2. The OpAmp is connected as an inverter to compensate the negative gain of the PMOS switch.

Figure 14. Drain Control through PMOS Switch

**NOTE:** The positive voltage generated by the Buffer stage can be used to supply the OpAmp and make it possible to drive a NMOS switch as a voltage follower. Doing so, the main advantage is to have a lower R<sub>dson</sub> switch and better intrinsic linearity.

In Figure 15, the plot illustrates the “open-loop” performance regarding temperature stability. The measured datas are displayed in a log-log scale in order to have a good representation of both the dynamic and the linearity of control. The variation of P<sub>out</sub> accross the frequency band are also very small (less than 1.0 dB ripple) and are kept to that small amount when controlling P<sub>out</sub> through the Drain voltage.

# MRFIC1819

**Figure 15. Temperature Stability of the Open Loop Control**

**Figure 16. Timing Guide**

## Burst mode

Use Figure 18 as a guide line to perform burst mode measurements with the complete application circuit of Figure 2. Notice that the V<sub>SC</sub> pin is connected to V<sub>ramp</sub> (through a resistor) and acts as a pull down when negative voltage is missing so that drain voltage is not applied to the RF line-up.

- Bursting the OpAmp with its Pin 8 (shdn) is not mandatory during a call as the OpAmp current consumption is very small (1.0 to 2mA). This pin is mainly used for the idle mode of the radio. In any case, the wake-up time of the OpAmp is very short.

- V<sub>ramp</sub> can be applied soon after Tx EN since the internal negative voltage generator settles in less than 2.0 μs.

- Tx EN signal can be used to switch the input power (using a driver or attenuator) in order to provide higher isolation for on/off burst dynamic.

## 1.9 GHz CDMA Upmixer/Exciter

The MRFIC1854 is an integrated upmixer and exciter amplifier designed specifically for PCS CDMA digital cellular radios. The exciter amplifier incorporates a temperature compensated linear gain control and selectable bias to reduce power consumption. The design utilizes Motorola's RF BiCMOS1 process to yield superior performance in a cost effective monolithic device.

- Total Supply Current CDMA Mode = 55 mA Typical
- 65 dB Dynamic Range Gain Control
- Upmixer Output IP3 = 6.0 dBm Typical
- Exciter Output IP3 = 22 dBm Typical
- Supply Voltage Range = 2.7 to 3.6 V
- Adjacent Channel Power (ACPR) @ 1.25 MHz Offset  
( $P_{out} = 3.0$  dBm) = -58 dBc Typical

## PIN FUNCTION DESCRIPTION

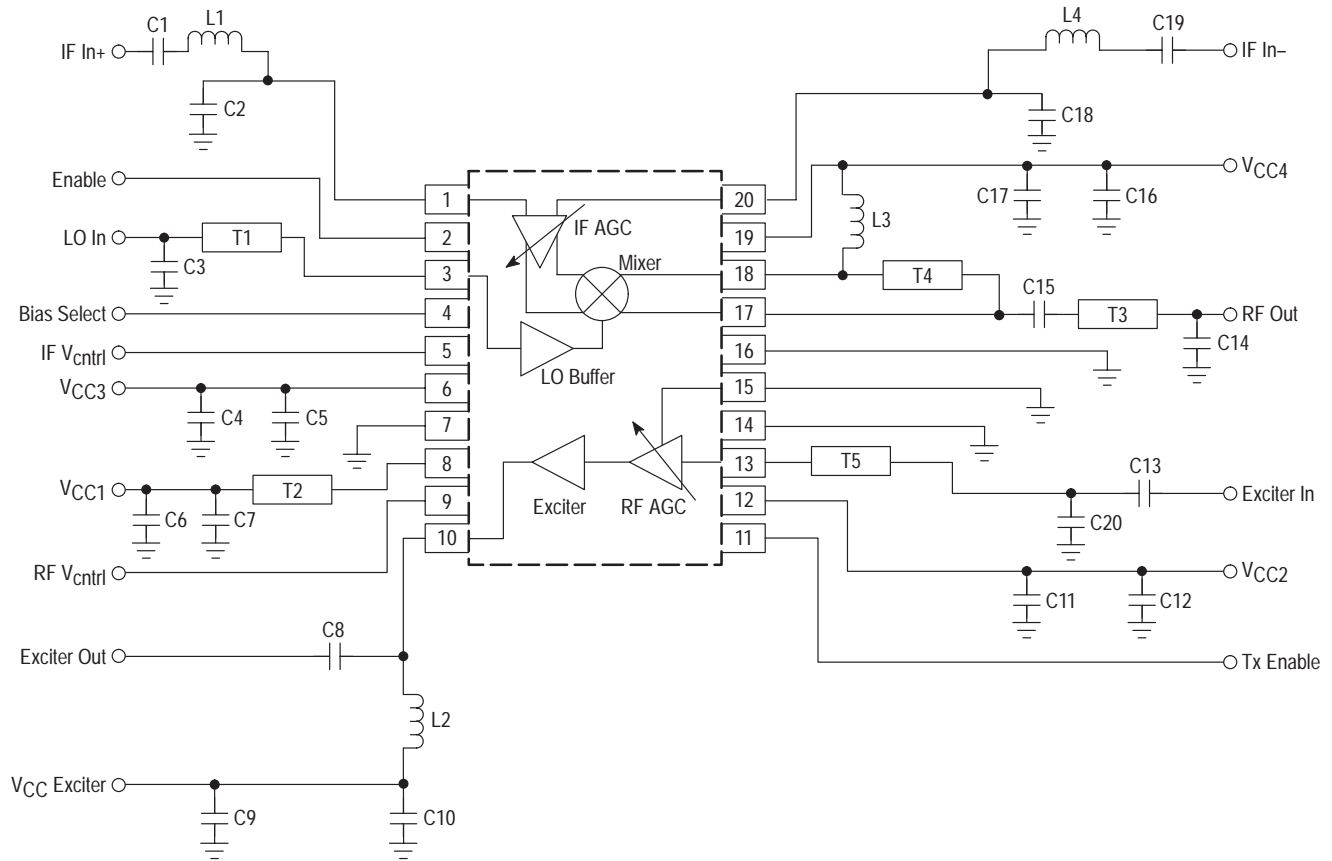

Pin	Function	Description	Voltage On (V)	Voltage Off (V)
1	IF In+	Mixer IF input pin. Input impedance is 500 Ω.	-33 dBm (Typ)	
2	Enable 1 (See Table 3)	Enable pin. A logic "High" (>2.4 V) enables entire chip and "Low" (<0.4 V) <b>disables chip</b> .	2.4 to 3.6	0 to 0.4
3	LO In	Mixer LO input pin.	-13 dBm (Typ)	
4	Bias Select	Bias select pin. Logic "Low" (<0.4 V) selects higher current bias for increased linearity and output power. "High" (>2.4 V) selects lower bias for reduced current consumption.		
5	IF AGC Control Voltage	IF AGC gain control pin. A 30 dB dynamic range can be achieved by adjusting voltage from 0.1 V (low gain) to 1.7 V (high gain).	0.1 to 1.7	
6	VCC3	Supply Voltage.	2.7 to 3.6	
7	Gnd	Ground connection.	-	
8	VCC1	Supply Voltage	2.7 to 3.6	
9	RF AGC Control Voltage	RF AGC control pin. A 30 dB dynamic range can be achieved by adjusting voltage from 0.1 V (low gain) to 1.7 V (high gain).	0.1 to 1.7	
10	Exciter Out	RF exciter amplifier output pin.	-	
11	Enable 2 (See Table 3)	Tx Enable pin. A logic "High" (>2.4 V) enables Tx path and "Low" (<0.4 V) <b>disables Tx path except LO Buffer</b> .	2.4 to 3.6	0 to 0.4
12	VCC2	Supply Voltage	2.7 to 3.6	
13	Exciter In	RF exciter amplifier input pin.	-	
14	Gnd	Ground connection.	-	
15	Gnd	Ground connection.	-	
16	Gnd	Ground connection.	-	
17	RF Out-	Mixer RF output pin.		
18	RF Out+	Mixer RF output pin.		
19	VCC4	Supply Voltage	2.7 to 3.6	
20	IF In-	Mixer IF input pin. Input impedance is 500 Ω.	-33 dBm (Typ)	

Table 1. Enable Truth Table

Enable 1	Enable 2	Mode
0	0	Disabled
0	1	Not Applicable
1	0	Standby Mode: Disables mixer/exciter, except LO buffer
1	1	Tx Enabled

## APPLICATION INFORMATION

### Design Philosophy

The MRFIC1854 has three operating states, enable, standby, and disable. These states are controlled by the truth table shown in Table 3. The device is fully operational during the enable state and the bias level can be selected. A high bias current for maximum power CDMA or a lower bias current for CDMA at lower powers can be selected via the Bias Select pin. In the high current CDMA mode, the quiescent current is increased to maximize the linearity of the device. In the lower current bias state, the quiescent current is reduced to save current during lower power CDMA operation. The standby mode can be used to reduce current consumption during Voice Activity Factoring. In the standby mode, the LO buffer remains on to prevent VCO pulling and the bandgap reference bias circuit remains on to assure rapid device turn on. Current consumption in standby mode is 10 mA typical. The disable mode is used to turn the MRFIC1854 completely off. Leakage current in this mode is only a few microamps.

The mixer is a double-balanced “Gilbert-cell” design with a balanced LO buffer amplifier. The input and output of the mixer are differential. The IF AGC is a differential amplifier that uses the “current steering” method for gain control. The IF AGC/mixer combination has 16 dB of gain and typically draws 20 mA quiescent current in the CDMA mode. An external filter is required between the mixer and RF AGC amplifier to reduce RX band noise.

Figure 1 shows the applications circuit for the MRFIC1854. In this circuit, the IF ports of the IF AGC have been matched to 50 Ω for testing purposes. In the actual application, the differential IF ports of the mixer would be impedance matched to an IF SAW filter. The differential impedance of the IF ports is 1600 ohms. The RF output of the mixer is configured as a differential output. A stripline balun is used to convert the RF output to single ended. DC current to the open collector output of the mixer is provided by inductor, L3 (18 nH) and transmission line, T4. Transmission lines T3 and T4, and capacitors C15 (30 pF) and C14 (3.6 pF) form the balun/output match for the mixer.

The RF AGC amplifier is a single-ended cascode design employing the standard “current steering” method of gain control. It’s ground is brought out through pin number 15 so inductance can be added to degenerate the gain for a lower noise floor. The maximum gain is around 13 dB. It typically

draws 9.0 mA quiescent current in CDMA mode. The RF  $V_{ctrl}$  signal is buffered with an on-chip OpAmp then preconditioned with temperature compensation and dB/V linearization before being applied to the RF AGC amplifier.

Transmission line T2 and capacitor C7 (47 pF) are for the interstage match between the RF AGC and the exciter amplifier.

The exciter amplifier is a simple common emitter design. It is grounded directly to the exposed pad which results in 12 dB of gain. It typically draws 24 mA bias current in CDMA. Inductor L2 (10 nH), capacitor C8 (30 pF), and C10 (30 pF) provide the output matching. L2 also provides a DC current path for the open collector output.

### Noise Power Considerations

In CDMA systems, the handset is required to dynamically adjust its output power to specific levels. This requires a dynamic range of as much as 90 dB from the transmitter. Another key performance specification in CDMA systems is the output noise power, both in band and out of band. Noise power specifications has caused the noise figure of the transmitter to become an important system consideration. The cascaded noise figure of the transmitter can be analyzed with the same equation used in receiver analysis. The only difference is the noise source is from the transmitter (modulator) instead of the atmosphere.

$$NF_{\text{cascaded}} = NF_1 + \frac{NF_2 - 1}{G_1} + \frac{NF_3 - 1}{G_1 G_2}$$

This equation above shows that the cascaded noise figure is better if the gain is higher and the noise figure is lower for the stages close to the noise source. For this reason, it is advantageous to implement some of the gain control of a CDMA transmitter in the RF section. The MRFIC1854 integrates a RF AGC amplifier after the upmixer to improve the overall noise figure of the transmitter.

# Dual-Band Dual Mode GaAs IPA

The MRFIC1856 is designed for dual-band subscriber equipment applications at 3.6 V in the 900 and 1800 MHz bands. The device incorporates two GaAs pHEMT amplifiers in one package allowing the most flexibility and highest performance while reducing board space. Target applications include dual-mode, dual-band handset for AMPS/DAMPS.

- Useable Frequency Range = 824 to 829 MHz AMPS/DAMPS and 1850 to 1910 MHz TDMA
- 3.6 V Operation
- 32 dBm Output Power AMPS
- 31 dBm Output Power DAMPS
- 30 dBm Output Power TDMA

## The MRFIC Line

# 900 MHz 2 Stage PA

The MRFIC2006 is an Integrated PA designed for linear operation in the 800 MHz to 1.0 GHz frequency range. The design utilizes Motorola's advanced MOSAIC 3 silicon bipolar RF process to yield superior performance in a cost effective monolithic device. Applications for the MRFIC2006 include CT-1 and CT-2 cordless telephones, remote controls, video and audio short range links, low cost cellular radios, and ISM band transmitters.

- 50 Ω Input and Output Impedance
- Typical Gain = 23 dB @ 900 MHz
- Bias Current Externally Adjustable
- Bias Pin can be used to Ramp or Disable
- Class A or AB Linear Operation
- Unconditionally Stable
- SO-8 Leaded Plastic Package
- Order MRFIC2006R2 for Tape & Reel.R2 Suffix
- Device Marking = M2006

NOT RECOMMENDED FOR NEW DESIGN  
DEVICE TO BE PHASED OUT.  
No replacement available.

## APPLICATIONS INFORMATION

### DESIGN PHILOSOPHY

The MRFIC2006 was designed for low cost and flexibility. Low cost was achieved by minimizing external components and using an SOIC package. Flexibility was achieved by allowing the bias current to be externally adjustable resulting in a broad range of output power capability. The bias pin can be ramped to reduce AM splatter in TDD/TDMA systems and can be used to trim the RF output power.

### THEORY OF OPERATION

The input port is internally matched to 50 ohms. Return loss is typically 15–16 dB in the 800–1000 MHz range. The output port is nearly 50 ohms but is an open collector and therefore requires an external bias inductor. Using an RF choke will result in a 11–12 dB output return loss. However, a 10 nH inductor will improve it to 15–20 dB. A 10 nH inductor is small enough in value to be printed on the board. DC blocks are required on the input and output. Values of 100 pF are recommended.

Supply decoupling must be done as close to the IC as possible. A 1000 pF capacitor is recommended. A series RF choke is recommended to keep the RF signal off the supply line. A 10 nF decoupling capacitor is recommended on the  $V_{\text{bias}}$  line but does not need to be very close to the IC.

The  $V_{\text{bias}}$  pin can be used several ways. Tying it directly to  $V_{\text{CC}}$  will maximize the bias current which will maximize linearity. Adding a series resistor will reduce the bias current which will improve efficiency. Figure 9 shows the efficiency versus output power with  $V_{\text{bias}}$  tied to  $V_{\text{CC}}$ . The series resistor will cause these curves to shift to the left. The RF output power can be trimmed by using a variable resistor. The  $V_{\text{bias}}$  pin can also be used to power down the IC or, in the case of TDD/TDMA systems, to ramp the IC. By applying a linear ramp voltage, such as the one provided by the MRFIC2004, it has been demonstrated to meet the CT2 Common Air Interface splatter specifications.

The MRFIC2006 is internally temperature compensated. For input powers of –5.0 to 0 dBm the output power temperature variation is typically less than 0.2 dB from –35 to +85°C.

### EVALUATION BOARDS

Evaluation boards are available for RF Monolithic Integrated Circuits by adding a “TF” suffix to the device type. For a complete list of currently available boards and ones in development for newly introduced product, please contact your local Motorola Distributor or Sales Office.

# Advance Information

## FSK FM IF Receiver BiCMOS

MC2800 is a high performance M-ary FSK FM IF Receiver for FLEX™ pagers. The circuit includes oscillator, mixer, IF amplifier, limiting IF circuitry, RSSI, quadrature discriminator, switchable bitrate filter, peak detector and A/D converter.

- 2/4 Level FSK Comparator and A/D Converter
- Fully Adaptive Data Slicer
- Coilless and Resonatorless Demodulator
- Current Consumption: 1.5 mA Typical
- Operating Voltage:  $V_{CC} = 1.1$  to  $3.0$  V,  $V_{DD} = 1.1$  to  $3.0$  V
- Input Bandwidth: 75 MHz
- Excellent Sensitivity:  $-110$  dBm
- Switchable Bitrate Filter up to 6400 b/s Data Rate
- Start-up Time: 5.0 ms
- 1.0 V Regulator with Source Capability of 5.0 mA Typical
- RSSI Function
- Low Battery Detector
- Small Package 5 x 5 32-Pin LQFP

FLEX is a trademark of Motorola, Inc.

## FUNCTIONAL DESCRIPTION

The complete circuit consists of the following functional blocks as shown in the Block Diagram on page 1.

### Oscillator

The oscillator is based on a transistor in common collector configuration. It requires two external capacitors and a crystal to form the tank circuit. External capacitors between base and emitter and from emitter to RF Pwr make the oscillator transistor to have a negative resistance for small signals which is the start-up condition for oscillation.

### Mixer

The mixer consists of input v-to-i stage and upper switching stage driven from the oscillator. The LO drive is fed from the built-in oscillator. The mixer output is obtained at Mix Out.

### IF Amplifier and Limiter

The first ceramic filter is to obtain the 455 kHz IF and to remove all other harmonics from the mixing process. The mixer output signal is then amplified in the first IF Amplifier. The signal is then fed into the second IF Amplifier through the second ceramic filter. The final IF signal can be monitored at the limiter output pin Lim Op.

### RSSI function

The RSSI function is an indication of the strength of the incoming signal.

### Demodulator

The limiter output @ 455 kHz is fed into the gyrator for carrier recovery and 90° phase shift. This LO signal is then mixed with the FSK signal fed by the IF Amp for demodulation. The demodulator output can be obtained at Det Out.

### Bit-Rate Filter

The cut-off frequencies of the filter can be determined by the 2.2 nF external capacitor between Pins BRF Out and BRF1, and the 22 nF external capacitor at Pin BRF2. The filter bandwidth can be switched by Pins R1 and R2 for both POCSAG and FLEX requirements.

### A/D Converter

The A/D converter features a fully adaptive data slicer. The input to the converter at Pin BRF Out is initially peak-detected. Its peak and valley voltages are obtained at Pins VPk P and VPk N. Three threshold voltages at 1/6, 1/2 and 5/6 of the input signal level are determined dynamically regardless the actual peak-to-peak value. The final digital data are obtained at Pins D1 and D2 depending upon the 2 or 4 levels FSK signal.

### Low Battery Detector

The battery low indicator senses the supply voltage and sets its output High when the voltage at input V<sub>CC</sub> is less than V<sub>th</sub> (typically 1.1 V).

### Band Gap Reference

The whole chip can be powered-up and powered-down by enabling and disabling the band gap reference via the Pin EN (Enable).

### 1.0 V Regulator

The 1.0 V voltage at Pin V<sub>reg</sub> is used to supply the regulated voltage for the oscillator and the mixer. It can also be used to supply other external circuits.

# MC2800

## PIN FUNCTION DESCRIPTION

Pin	Symbol	Schematic (Excluding ESD)	Description
1	EN		Enables the circuit.
2	CL (Precharge and Reset)		This pin is used to precharge the circuit to accelerate the initial start-up process (particularly the 4.7 μF capacitor at Pin 10).
3 4	R1 R2		These pins are set to "high" or "low". They are used for the selection of the filter's symbol rate.
5	BRF Out		Symbol Rate Filter Output for connection of feedback capacitor. This is also the audio output before A/D.
6	BRF2		Symbol Rate Filter Input for connection of filter capacitor.
7	BRF1		Symbol Rate Filter Input.
8	Det Out		Audio output from FSK FM detector. This pin is also audio input for testing purposes (signal of 100 mVpp with DC offset of 0.9 V).
9	Gnd		Ground pin for IC covering Pins 1 through 13 and 27 through 32.

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Schematic (Excluding ESD)	Description
17	IF1 Out		First IF Amplifier output.
18	Gnd		Ground pin for IC covering Pins 14 through 20.
19	IF1 In		First IF Amplifier input.
20	VCC		Main Analog Power Supply for the circuit.
21	Mix Out		Mixer Output.
22	Mix Gnd		Ground pin for the RF Part.
23	Mix In		Mixer input relative to Pin 22.
24	RF Pwr		Power Supply for the RF part. It is not internally connected to the other Power Supply. It must be connected externally to Vreg 1.0 V, with the appropriate decoupling.
25 26	Osc E Osc B		These pins form the reference oscillator when connected to an external parallel-resonant crystal (17.445 MHz typical).
27	Vreg 1.0 V		1.0 V regulator output. Minimum 1.0 μF capacitor required for decoupling. It can supply up to 3.0 mA for external use.

## MC2800

### MC2800 Application Board

The typical application circuit of MC2800 is shown in Figure 5. The performance of the system kit consisting of the MC2800, MC68175 and MC68HC705L32 is measured. The system has a typical sensitivity of  $-115$  dBm @ Phase A. Table 1 shows the sensitivity measurements of the system at different symbol rates along with the Symbol Rate Filter (SRF) filter selections. The test input to the MC2800 is a single message of 12 characters. The first two columns of Table 1 show the SRF's R1 and R2 conditions during synchronization. The third and fourth columns show the R1 and R2 conditions during data sampling. In operation, the original digital baseband data is encoded by the Encoder Software in the computer before this encoded message is sent out via the Data Acquisition card (DAQ) to the signal generator HP8657B. The MC2800 receives the modulated signal from the HP8657B and then converts it into baseband data D1 and D2. When retrieving data from Pins D1 and D2, it is essential to observe the timing requirements for the EN and CL signals. This is illustrated in EN and CL Timing Requirements. The computer at the other end then retrieves the D1 and D2 data through the L32EVS board and displays it in the HC05 Pager Development Board. The test setup of this system measurement is shown in Figure 6.

With the input frequency at 17.9 MHz the input impedance of the mixer is measured to be  $2.1k-j2.67$  k $\Omega$ . The input impedance does not vary significantly with the supply voltage and frequency of interest. Figure 7 shows the input impedance of the mixer over a range of frequencies in the Smith Chart. From the Smith Chart, the matching network connecting between the 50  $\Omega$  signal generator and the MC2800 mixer is worked out to be consisting of a shunt inductor of 3.8  $\mu$ H and a series capacitor of 19 pF. A varicap of 10 to 90 pF is selected for the series capacitor as this will make the fine tuning of the input stage easier. The other input to the mixer is internally connected to a Local Oscillator (LO). The LO has a Colpitts amplifier which amplifies the external crystal frequency of 17.445 MHz. The natural oscillation frequency of the crystal is not exactly 17.445 MHz, therefore the capacitor C4 is set to 47 pF and the varicap C18 is selected to have a range of 6.0 to 45 pF for making sure that the LO can oscillate at 17.445 MHz. The conversion voltage gain of the mixer is about 20 dB @  $-110$  dBm. Table 2 shows the mixer gain with different input signal levels. After the input signal is amplified and down converted to 455 kHz, it is then filtered before entering the amplifier 1st IF Amp. The voltage gain of this amplifier is measured to be 40 dB. This is shown

in Figure 8. From the first stage of amplification the input signal strength is also detected and it can be monitored at the RSSI Pin. The relationship between the input signal strength and the RSSI output is shown in Figure 9. In applications where component cost is critical, the second 455 kHz ceramic filter may be replaced by an LC  $\pi$  network. This is shown in Figure 10. The 1.0  $\mu$ F capacitors are used for blocking dc voltages. The network consisting of 560 pF capacitors and the 470  $\mu$ H inductor acts as both a low pass filter centered at 455 kHz and a matching between the first amplifier output and the second amplifier input. The output resistance of the first amplifier is 1.1 k $\Omega$  and the input resistance of the second amplifier is 1.5 k $\Omega$ . Based on the setup as shown previously in Figure 6, the system performance of the MC2800 (one 455 kHz ceramic filter plus one LC network combination) together with the MC68175 and the MC68HC705L32 is measured and the test result is tabulated in Table 3.

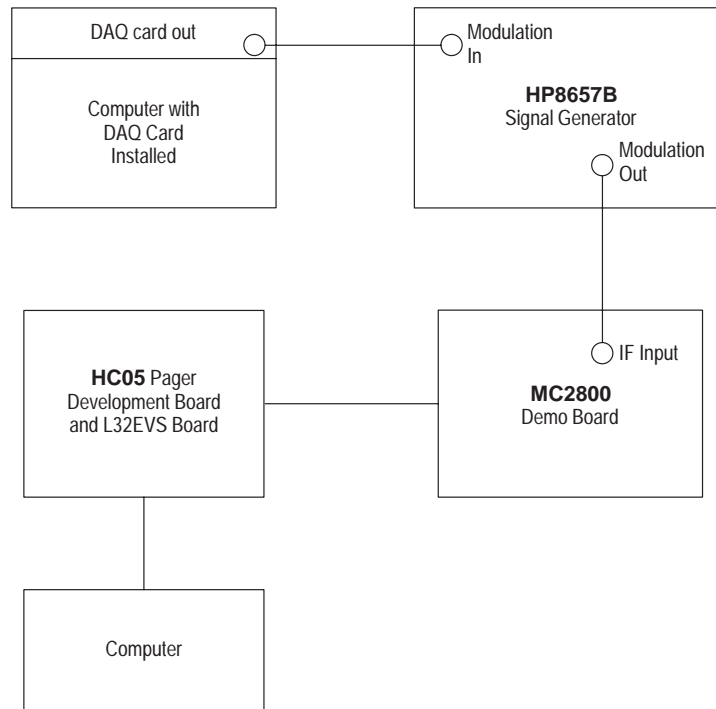

Coming back to the device MC2800, the demodulator is coilless and it does not need any resonator. The external resistor connected to the pin Bias Ref is used to give the reference bias loop current for the demodulator. The frequency response of the demodulator is measured and it is shown in Figure 11. At the Demodulator Output (Det Out Pin) a capacitor is used to decouple the high frequency noise. Figure 12 shows the differences of the signal measured at this pin with different values of capacitors used. This highlights the importance in the selection of this capacitor value. If this value is too small then the SINAD will be very poor and hence the sensitivity will be very bad. If it is too big then the high frequency contents in the step input signal will be decoupled and this will make the decoding very difficult after analog to digital conversion. The SRF filter is a two pole active filter. The filter characteristics are plotted in Figure 14 and Figure 15 for which the selections of R1 = 0 and R2 = 1 are used during measurements. R1 and R2 are used to select the amount of resistors in the filter. The four level Data Slicer converts the analog signal into D1 and D2 digital outputs. This A-D conversion is best illustrated by the plots in Figures 16 and 17. A brief outline of the A-D conversion can be found in Data Slicer A/D Conversion. Figure 22 shows how the MC2800 is connected to the decoding device (MC68175) which is used after analog to digital conversion. The interface between the two devices is tabulated in Table 6. The operating procedure is also outlined.

**EN and CL Timing Requirements**

When power is first applied to the MC2800 the capacitor connecting to the Pin PH Cont is pre-charged to 0.9 V. The voltages at Pins EN and CL must be set to high during this Power On cycle of time. In the typical system application as shown in Figure 6 the voltage at Pin EN is pulled to high for a duration of 60 seconds at first. During this period the device MC2800 is enabled and data at Pins D1 and D2 is valid 6.0 ms after EN is high. When EN goes high, CL can also go high at the same instance without any delay. The purpose of pulling CL to high is to set up the voltages at Pins 31 and 32. It has been tried that 4.0 ms is adequate to get these pins to the

correct voltages. However some delay must be allowed for the transient to die down after CL goes low. In application, it is observed that the data D1 and D2 will be valid 2.0 ms after CL goes low in this receive cycle. When there is no incoming message to receive, it is best to disable the MC2800 to save power. In this idle cycle, the MC2800 is disabled most of the time and it is enabled once every 1.5 s (or in some cases 1.875 s) to open the channel for the MCU to detect if there is any message coming in or not. These typical conditions are all illustrated in Figure 18.

Figure 18. Timing of EN and CL

# MC2800

## Low Pass Bit-Rate Filter

This section is a short description of the Architecture of the Bit-Rate Filter used in the MC2800.

Figure 19.

Based on the schematics described above, the equation of this filter is:

$$\frac{v_o}{v_i}(s) = \frac{-\frac{2A_o}{1+A_o}}{1 + s2RC_2 + \frac{2}{1+A_o}(1 + s4RC_1 + s^22R^2C_1C_2)}$$

$$= -\frac{\frac{2A_o}{3+A_o}}{\left(1 + \frac{s}{p_1}\right)\left(1 + \frac{s}{p_2}\right)}$$

Assume  $A_o = 200$ , and  $C_1 = 10C_2$ , this equation can be simplified as:

$$p_1 = -\frac{0.44}{RC_2} \quad \text{and} \quad p_2 = -\frac{11.56}{RC_2}$$

With the different combinations of  $R_1$ ,  $R_2$  to setup the Bit-Rate Filter, the cut-off frequencies has been defined according to the table below:

Table 4. Bit-Rate Filter Frequency Responses  
(assume  $C_1 = 10C_2 = 22 \text{ nF}$ )

R1	R2	R/kΩ	$f_{p1}$ /Hz	$f_{p2}$ /Hz
0	0	84.0	379	9.96 k
1	0	35.6	894	23.5 k
1	1	26.5	1.20 k	31.6 k
0	1	12.8	2.49 k	65.3 k

A typical frequency response of the bit-rate filter is shown in Figure 20.

Figure 20. Gain Response of the Bit-Rate Filter

# MC2800

## Data Slicer A/D Conversion

In the data slicer of the MC2800 there is a block of comparators which can compare four different kinds of input voltage levels. This “4 level” comparator compares the incoming signal (BRF Out) and then turns it into digital D1 and D2 outputs. This is shown graphically in Figure 21. The state table of D1 and D2 is shown in Table 5.

**Table 5. State Table of D1 and D2**

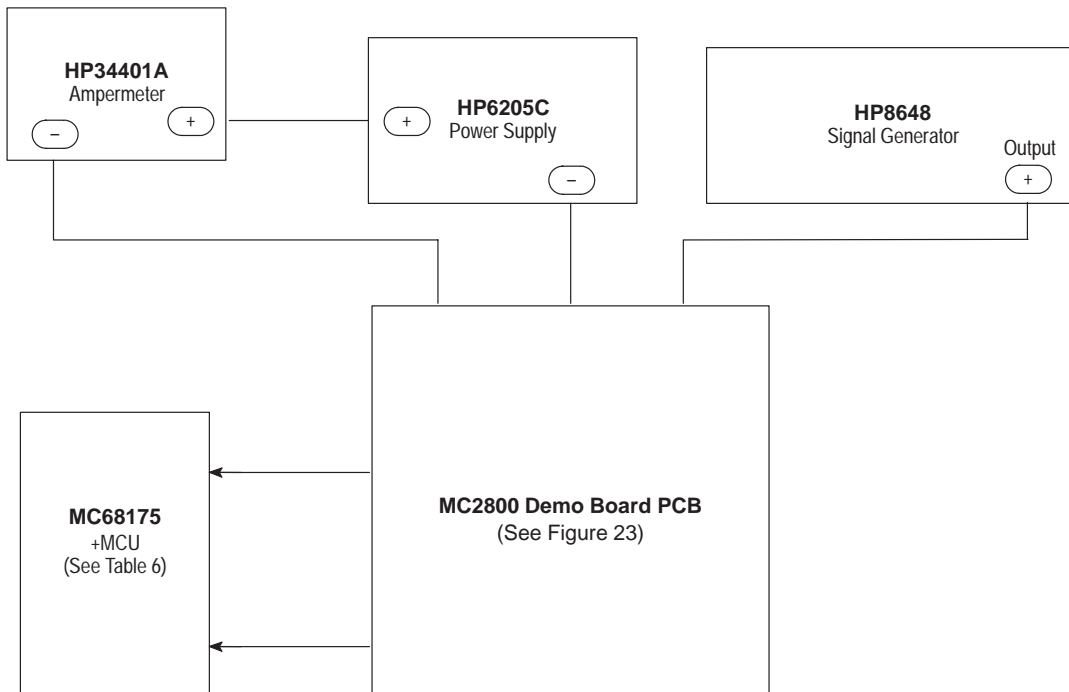

Frequency Deviation	D1	D2
4.8 kHz	0	0
1.6 kHz	0	1
-1.6 kHz	1	1
-4.8 kHz	1	0

## Operating Procedures

1. Connect up the circuit as shown in Figure 22.
2. Set the power supply to 1.4 V (typical value of an AA battery).
3. Set the HP8648A signal generator to the following:

```
FORMAT FLEX
POLARITY NORMAL      FILTER ON
ROAMING MODE         NONE

CYCLE 00 FRAME 000 PHASE A
COLLAPSE CYCLE 0

ADDRESS TYPE SHORT
ADDRESS1 2031715

PAGER CODE A0000001
DUMMY CALL OFF

IMMEDIATE STOP OFF
HEADER ON TERMINATOR ON

MODE SINGLE AMPLITUDE –110 dBm

MESSAGE NO.6 MESSAGE LENGTH 10
1234567890

VECTOR TYPE STANDARD

DATA RATE 6400/4
PAGER TYPE NUMERIC
```

4. Connect V<sub>DD</sub> (Pin 19 of Interface Connector) to the digital voltage supply (usually 3.0 V).
5. Connect the MC2800 to the Flex decoder MC68175 as shown in Table 6. For example, Pin 1 of MC2800 is connected to Pin 22 of MC68175 via the Interface Connector Pin 8.
6. Program the MCU such that it can generate the timing for the EN and CL Pins as shown in Figure 18.

# MC3356

## Wideband FSK Receiver

The MC3356 includes Oscillator, Mixer, Limiting IF Amplifier, Quadrature Detector, Audio Buffer, Squelch, Meter Drive, Squelch Status output, and Data Shaper comparator. The MC3356 is designed for use in digital data communications equipment.

- Data Rates up to 500 kilobaud
- Excellent Sensitivity: -3 dB Limiting Sensitivity  
30  $\mu$ Vrms @ 100 MHz
- Highly Versatile, Full Function Device, yet Few External Parts are Required
- Down Converter Can be Used Independently — Similar to NE602

## GENERAL DESCRIPTION

This device is intended for single and double conversion VHF receiver systems, primarily for FSK data transmission up to 500 K baud (250 kHz). It contains an oscillator, mixer, limiting IF, quadrature detector, signal strength meter drive, and data shaping amplifier.

The oscillator is a common base Colpitts type which can be crystal controlled, as shown in Figure 1, or L-C controlled as shown in the other figures. At higher  $V_{CC}$ , it has been operated as high as 200 MHz. A mixer/oscillator voltage gain of 2 up to approximately 150 MHz, is readily achievable.

The mixer functions well from an input signal of 10  $\mu\text{Vrms}$ , below which the squelch is unpredictable, up to about 10 mVrms, before any evidence of overload. Operation up to 1.0 Vrms input is permitted, but non-linearity of the meter output is incurred, and some oscillator pulling is suspected. The AM rejection above 10 mVrms is degraded.

The limiting IF is a high frequency type, capable of being operated up to 50 MHz. It is expected to be used at 10.7 MHz in most cases, due to the availability of standard ceramic resonators. The quadrature detector is internally coupled to the IF, and a 5.0 pF quadrature capacitor is internally provided. The -3dB limiting sensitivity of the IF itself is approximately 50  $\mu\text{V}$  (at Pin 7), and the IF can accept signals up to 1.0 Vrms without distortion or change of detector quiescent dc level.

The IF is unusual in that each of the last 5 stages of the 6 state limiter contains a signal strength sensitive, current sinking device. These are parallel connected and buffered to produce a signal strength meter drive which is fairly linear for IF input signals of 10  $\mu\text{V}$  to 100 mVrms (see Figure 4).

A simple squelch arrangement is provided whereby the meter current flowing through the meter load resistance flips a comparator at about 0.8 Vdc above ground. The signal strength at which this occurs can be adjusted by changing the meter load resistor. The comparator (+) input and output are available to permit control of hysteresis. Good positive

action can be obtained for IF input signals of above 30  $\mu\text{Vrms}$ . The 130 k $\Omega$  resistor shown in the test circuit provides a small amount of hysteresis. Its connection between the 3.3 k resistor to ground and the 3.0 k pot, permits adjustment of squelch level without changing the amount of hysteresis.

The squelch is internally connected to both the quadrature detector and the data shaper. The quadrature detector output, when squelched, goes to a dc level approximately equal to the zero signal level unsquelched. The squelch causes the data shaper to produce a high ( $V_{CC}$ ) output.

The data shaper is a complete "floating" comparator, with back to back diodes across its inputs. The output of the quadrature detector can be fed directly to either input of this amplifier to produce an output that is either at  $V_{CC}$  or  $V_{EE}$ , depending upon the received frequency. The impedance of the biasing can be varied to produce an amplifier which "follows" frequency detuning to some degree, to prevent data pulse width changes.

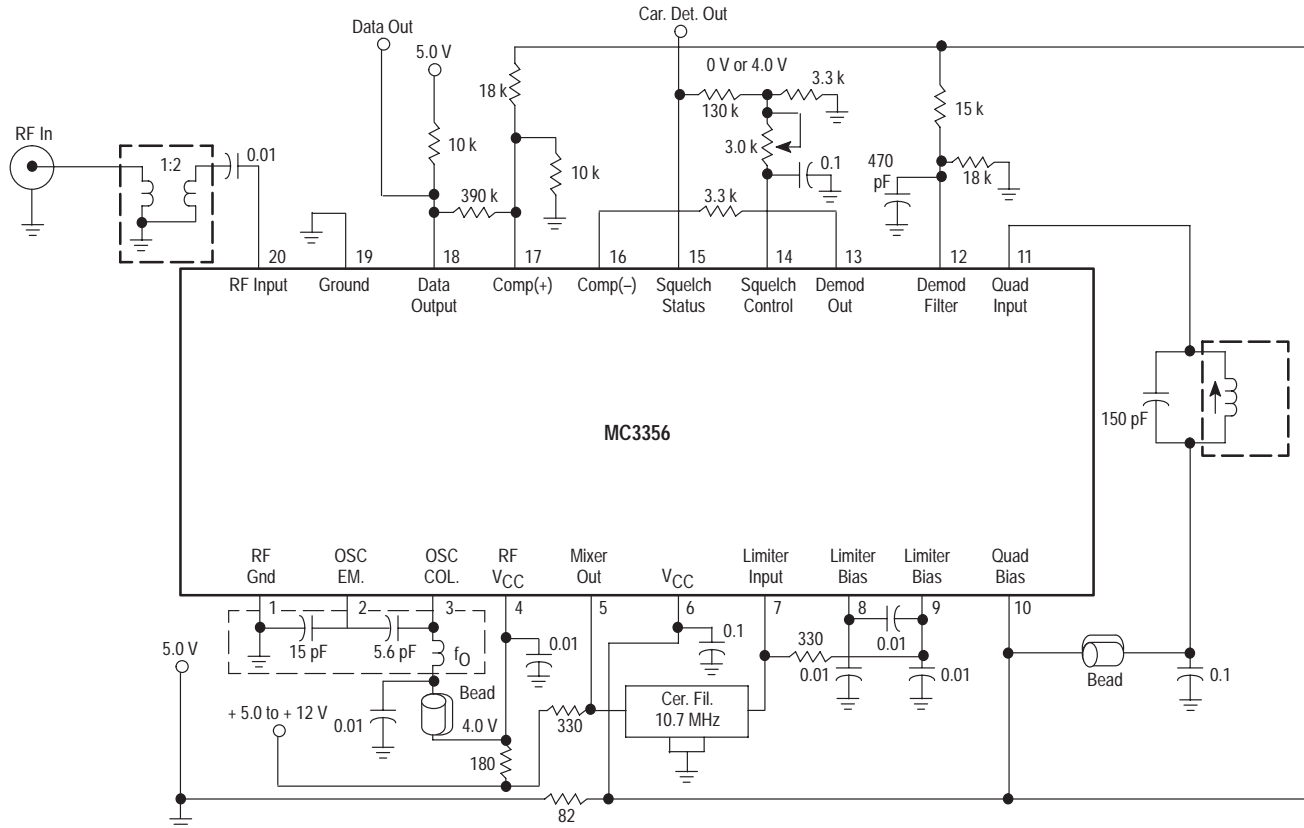

When the data shaper is driven directly from the demodulator output, Pin 13, there may be distortion at Pin 13 due to the diodes, but this is not important in the data application. A useful note in relating high/low input frequency to logic state: low IF frequency corresponds to low demodulator output. If the oscillator is above the incoming RF frequency, then high RF frequency will produce a logic low (input to (+) input of Data Shaper as shown in Figures 1 and 2).

## APPLICATION NOTES

The MC3356 is a high frequency/high gain receiver that requires following certain layout techniques in designing a stable circuit configuration. The objective is to minimize or eliminate, if possible, any unwanted feedback.

# MC3356

Figure 5. Application with Fixed Bias on Data Shaper

## APPLICATION NOTES (continued)

Shielding, which includes the placement of input and output components, is important in minimizing electrostatic or electromagnetic coupling. The MC3356 has its pin connections such that the circuit designer can place the critical input and output circuits on opposite ends of the chip. Shielding is normally required for inductors in tuned circuits.

The MC3356 has a separate  $V_{CC}$  and ground for the RF and IF sections which allows good external circuit isolation by minimizing common ground paths.

Note that the circuits of Figures 1 and 2 have RF, Oscillator, and IF circuits predominantly referenced to the plus supply rails. Figure 5, on the other hand, shows a suitable means of ground referencing. The two methods produce identical results when carefully executed. It is important to treat Pin 19 as a ground node for either approach. The RF input should be "grounded" to Pin 1 and then the input and the mixer/oscillator grounds (or RF  $V_{CC}$  bypasses) should be connected by a low inductance path to Pin 19. IF and detector sections should also have their

bypasses returned by a **separate** path to Pin 19.  $V_{CC}$  and RF  $V_{CC}$  can be decoupled to minimize feedback, although the configuration of Figure 2 shows a successful implementation on a common 5.0 V supply. Once again, the message is: define a supply node and a ground node and return each section to those nodes by separate, low impedance paths.

The test circuit of Figure 2 has a 3 dB limiting level of 30  $\mu\text{V}$  which can be lowered 6 db by a 1:2 untuned transformer at the input as shown in Figures 5 and 6. For applications that require additional sensitivity, an RF amplifier can be added, but with no greater than 20 db gain. This will give a 2.0 to 2.5  $\mu\text{V}$  sensitivity and any additional gain will reduce receiver dynamic range without improving its sensitivity. Although the test circuit operates at 5.0 V, the mixer/oscillator optimum performance is at 8.0 V to 12 V. A minimum of 8.0 V is recommended in high frequency applications (above 150 MHz), or in PLL applications where the oscillator drives a prescaler.

# MC3356

**Figure 6. Application with Self-Adjusting Bias on Data Shaper**

## APPLICATION NOTES (continued)

Depending on the external circuit, inverted or noninverted data is available at Pin 18. Inverted data makes the higher frequency in the FSK signal a “one” when the local oscillator is above the incoming RF. Figure 5 schematic shows the comparator with hysteresis. In this circuit the dc reference voltage at Pin 17 is about the same as the demodulated output voltage (Pin 13) when no signal is present. This type circuit is preferred for systems where the data rates can drop to zero. Some systems have a low frequency limit on the data rate, such as systems using the MC3850 ACIA that has a start or stop bit. This defines the low frequency limit that can appear in the data stream.

Figure 5 circuit can then be changed to a circuit configuration as shown in Figure 6. In Figure 6 the reference voltage for the comparator is derived from the demodulator output through a low pass circuit where  $\tau$  is much lower than the lowest frequency data rate. This and similar circuits will compensate for small tuning changes (or drift) in the quadrature detector.

Squelch status (Pin 15) goes high (squelch off) when the input signal becomes greater than some preset level set by the resistance between Pin 14 and ground. Hysteresis is added to the circuit externally by the resistance from Pin 14 to Pin 15.

# Low Power Narrowband FM IF

The MC3361B includes an Oscillator, Mixer, Limiting Amplifier, Quadrature Discriminator, Active Filter, Squelch, Scan Control and Mute Switch. This device is designed for use in FM dual conversion communications equipment.

- Operates from 2.0 to 8.0 V Supply
- Low Drain Current 3.9 mA Typical @  $V_{CC} = 4.0$  Vdc
- Excellent Sensitivity: Input Limiting Voltage  $-3.0$  dB =  $2.6$   $\mu$ V Typical
- Low Number of External Parts Required
- Operating Frequency Up to 60 MHz

# Low Power Narrowband FM IF

The MC3371 and MC3372 perform single conversion FM reception and consist of an oscillator, mixer, limiting IF amplifier, quadrature discriminator, active filter, squelch switch, and meter drive circuitry. These devices are designed for use in FM dual conversion communication equipment. The MC3371/MC3372 are similar to the MC3361/MC3357 FM IFs, except that a signal strength indicator replaces the scan function controlling driver which is in the MC3361/MC3357. The MC3371 is designed for the use of parallel LC components, while the MC3372 is designed for use with either a 455 kHz ceramic discriminator, or parallel LC components.

These devices also require fewer external parts than earlier products. The MC3371 and MC3372 are available in dual-in-line and surface mount packaging.

- Wide Operating Supply Voltage Range:  $V_{CC} = 2.0$  to  $9.0$  V
- Input Limiting Voltage Sensitivity of  $-3.0$  dB
- Low Drain Current:  $I_{CC} = 3.2$  mA, @  $V_{CC} = 4.0$  V, Squelch Off
- Minimal Drain Current Increase When Squelched
- Signal Strength Indicator: 60 dB Dynamic Range
- Mixer Operating Frequency Up to 100 MHz
- Fewer External Parts Required than Earlier Devices

## MC3371 PIN FUNCTION DESCRIPTION

**OPERATING CONDITIONS**  $V_{CC} = 4.0 \text{ Vdc}$ ,  $R_{FIn} = 100 \mu\Omega$ ,  $f_{mod} = 1.0 \text{ kHz}$ ,  $f_{dev} = 3.0 \text{ kHz}$ . MC3371 at  $f_{RF} = 10.7 \text{ MHz}$  (see Figure 11).

Pin	Symbol	Internal Equivalent Circuit	Description	Waveform
1	OSC1		The base of the Colpitts oscillator. Use a high impedance and low capacitance probe or a "sniffer" to view the waveform without altering the frequency. Typical level is 450 mVpp.	
2	OSC2		The emitter of the Colpitts oscillator. Typical signal level is 200 mVpp. Note that the signal is somewhat distorted compared to that on Pin 1.	
3	MXOut		Output of the Mixer. Riding on the 455 kHz is the RF carrier component. The typical level is approximately 60 mVpp.	
4	VCC		Supply Voltage -2.0 to 9.0 Vdc is the operating range. VCC is decoupled to ground.	
5	IFIn		Input to the IF amplifier after passing through the 455 kHz ceramic filter. The signal is attenuated by the filter. The typical level is approximately 50 mVpp.	
6	DEC1		IF Decoupling. External 0.1 μF capacitors connected to VCC.	
7	DEC2		IF Decoupling. External 0.1 μF capacitors connected to VCC.	
8	Quad Coil		Quadrature Tuning Coil. Composite (not yet demodulated) 455 kHz IF signal is present. The typical level is 500 mVpp.

Figure 9. MC3371 Circuit Schematic

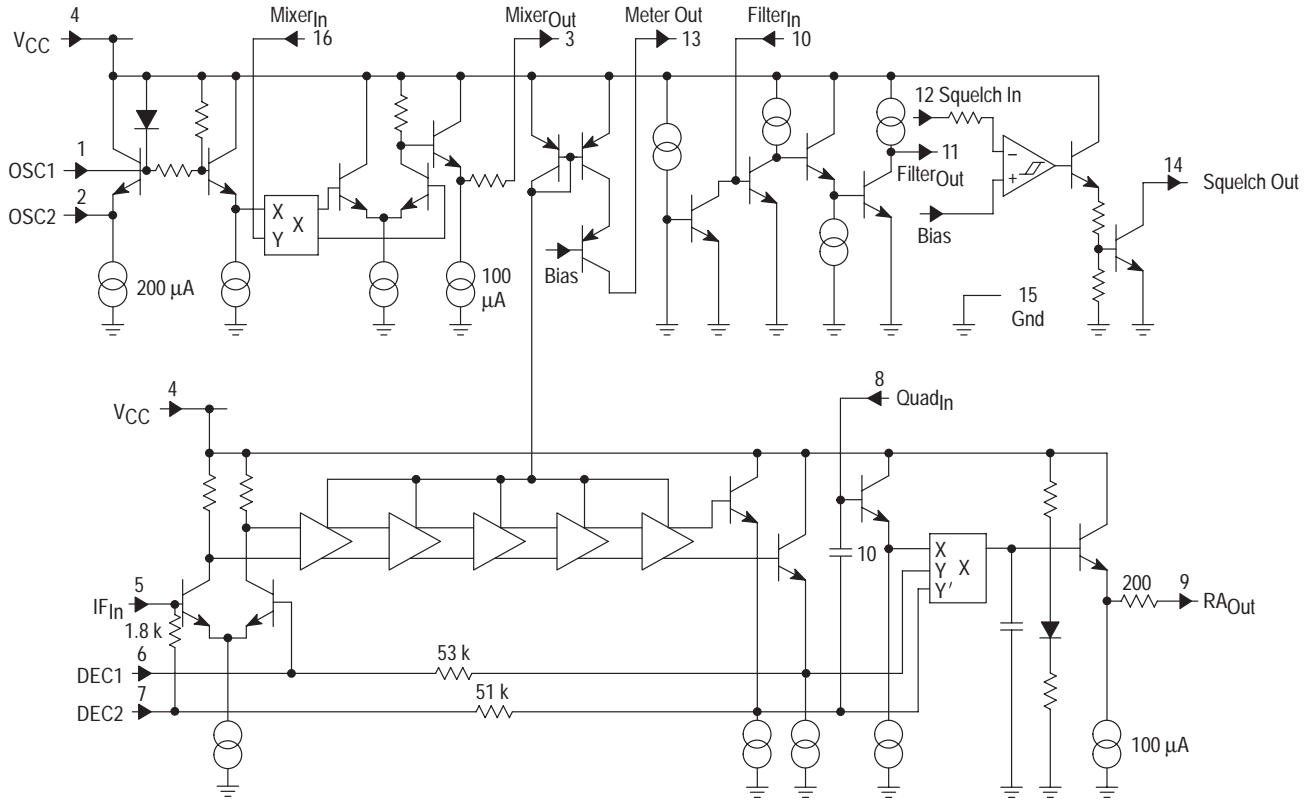

Figure 10. MC3372 Circuit Schematic

## CIRCUIT DESCRIPTION

The MC3371 and MC3372 are low power narrowband FM receivers with an operating frequency of up to 60 MHz. Its low voltage design provides low power drain, excellent sensitivity, and good image rejection in narrowband voice and data link applications.

This part combines a mixer, an IF (intermediate frequency) limiter with a logarithmic response signal strength indicator, a quadrature detector, an active filter and a squelch trigger circuit. In a typical application, the mixer amplifier converts an RF input signal to a 455 kHz IF signal. Passing through an external bandpass filter, the IF signal is fed into a limiting amplifier and detection circuit where the audio signal is recovered. A conventional quadrature detector is used.

The absence of an input signal is indicated by the presence of noise above the desired audio frequencies. This "noise band" is monitored by an active filter and a detector. A squelch switch is used to mute the audio when noise or a tone is present. The input signal level is monitored by a meter drive circuit which detects the amount of IF signal in the limiting amplifier.

## APPLICATIONS INFORMATION

The oscillator is an internally biased Colpitts type with the collector, base, and emitter connections at Pins 4, 1 and 2 respectively. This oscillator can be run under crystal control. For fundamental mode crystals use crystal characterized parallel resonant for 32 pF load. For higher frequencies, use 3rd overtone series mode type crystals. The coil (L2) and resistor RD (R13) are needed to ensure proper and stable operation at the LO frequency (see Figure 13, 45 MHz application circuit).

The mixer is doubly balanced to reduce spurious radiation. Conversion gain stated in the AC Electrical Characteristics table is typically 20 dB. This power gain measurement was made under stable conditions using a 50  $\Omega$  source at the input and an external load provided by a 455 kHz ceramic filter at the mixer output which is connected to the  $V_{CC}$  (Pin 4) and IF input (Pin 5). The filter impedance closely matches the 1.8 k $\Omega$  internal load resistance at Pin 3 (mixer output). Since the input impedance at Pin 16 is strongly influenced by a 3.3 k $\Omega$  internal biasing resistor and has a low capacitance, the useful gain is actually much higher than shown by the standard power gain measurement. The Smith Chart plot in Figure 17 shows the measured mixer input impedance versus input frequency with the mixer input matched to a 50  $\Omega$  source impedance at the given frequencies. In order to assure stable operation under matched conditions, it is necessary to provide a shunt resistor to ground. Figures 11, 12 and 13 show the input networks used to derive the mixer input impedance data.

Following the mixer, a ceramic bandpass filter is recommended for IF filtering (i.e. 455 kHz types having a bandwidth of  $\pm 2.0$  kHz to  $\pm 15$  kHz with an input and output impedance from 1.5 k $\Omega$  to 2.0 k $\Omega$ ). The 6 stage limiting IF

amplifier has approximately 92 dB of gain. The MC3371 and MC3372 are different in the limiter and quadrature detector circuits. The MC3371 has a 1.8 k $\Omega$  and a 51 k $\Omega$  resistor providing internal dc biasing and the output of the limiter is internally connected, both directly and through a 10 pF capacitor to the quadrature detector; whereas, in the MC3372 these components are not provided internally. Thus, in the MC3371, no external components are necessary to match the 455 kHz ceramic filter, while in the MC3372, external 1.8 k $\Omega$  and 51 k $\Omega$  biasing resistors are needed between Pins 5 and 7, respectively (see Figures 12 and 13).

In the MC3371, a parallel LCR quadrature tank circuit is connected externally from Pin 8 to  $V_{CC}$  (similar to the MC3361). In the MC3372, a quadrature capacitor is needed externally from Pin 7 to Pin 8 and a parallel LC or a ceramic discriminator with a damping resistor is also needed from Pin 8 to  $V_{CC}$  (similar to the MC3357). The above external quadrature circuitry provides 90° phase shift at the IF center frequency and enables recovered audio.

The damping resistor determines the peak separation of the detector and is somewhat critical. As the resistor is decreased, the separation and the bandwidth is increased but the recovered audio is decreased. Receiver sensitivity is dependent on the value of this resistor and the bandwidth of the 455 kHz ceramic filter.

On the chip the composite recovered audio, consisting of carrier component and modulating signal, is passed through a low pass filter amplifier to reduce the carrier component and then is fed to Pin 9 which has an output impedance of 450  $\Omega$ . The signal still requires further filtering to eliminate the carrier component, deemphasis, volume control, and further amplification before driving a loudspeaker. The relative level of the composite recovered audio signal at Pin 9 should be considered for proper interaction with an audio post amplifier and a given load element. The MC13060 is recommended as a low power audio amplifier.

The meter output indicates the strength of the IF level and the output current is proportional to the logarithm of the IF input signal amplitude. A maximum source current of 60  $\mu$ A is available and can be used to drive a meter and to detect a carrier presence. This is referred to as a Received Strength Signal Indicator (RSSI). The output at Pin 13 provides a current source. Thus, a resistor to ground yields a voltage proportional to the input carrier signal level. The value of this resistor is estimated by  $(V_{CC}(V_{dc}) - 1.0 \text{ V})/60 \mu\text{A}$ ; so for  $V_{CC} = 4.0 \text{ Vdc}$ , the resistor is approximately 50 k $\Omega$  and provides a maximum voltage swing of about 3.0 V.

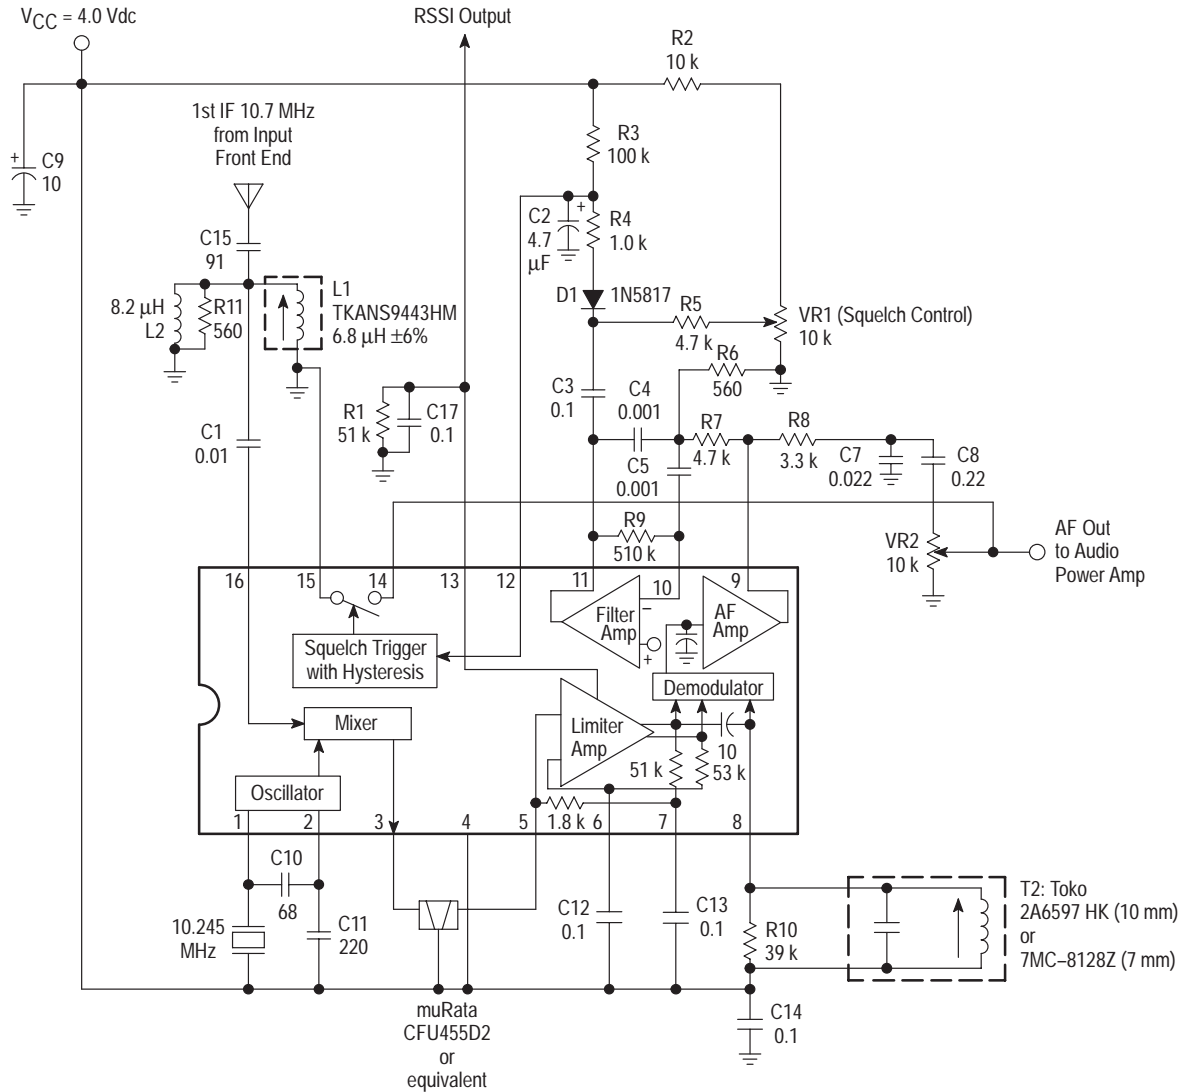

A simple inverting op amp has an output at Pin 11 and the inverting input at Pin 10. The noninverting input is connected to 2.5 V. The op amp may be used as a noise triggered squelch or as an active noise filter. The bandpass filter is designed with external impedance elements to discriminate between frequencies. With an external AM detector, the filtered audio signal is checked for a tone signal or for the presence of noise above the normal audio band. This information is applied to Pin 12.

## MC3371 MC3372

An external positive bias to Pin 12 sets up the squelch trigger circuit such that the audio mute (Pin 14) is open or connected to ground. If Pin 12 is pulled down to 0.9 V or below by the noise or tone detector, Pin 14 is internally shorted to ground. There is about 57 mV of hysteresis at Pin 12 to prevent jitter. Audio muting is accomplished by connecting Pin 14 to the appropriate point in the audio path between Pin 9 and an audio amplifier. The voltage at Pin 14 should not be lower than  $-0.7$  V; this can be assured by connecting Pin 14 to the point that has no dc component.

Another possible application of the squelch switch may be as a carrier level triggered squelch circuit, similar to the MC3362/MC3363 FM receivers. In this case the meter output can be used directly to trigger the squelch switch when the RF input at the input frequency falls below the desired level. The level at which this occurs is determined by the resistor placed between the meter drive output (Pin 13) and ground (Pin 15).

# Low Voltage FM Narrowband Receiver

... with single conversion circuitry including oscillator, mixer, IF amplifiers, limiting IF circuitry, and quadrature discriminator. The MC3374 is perfect for narrowband audio and data applications up to 75 MHz which require extremely low power consumption. Battery powered applications down to  $V_{CC} = 1.1\text{ V}$  are possible. The MC3374 also includes an on-board voltage regulator, low battery detection circuitry, a receiver enable allowing a power down Sleep-Mode™, two undedicated buffer amplifiers to allow simultaneous audio and data reception, and a comparator for enhancing FSK (Frequency Shift Keyed) data reception to 1200 baud.

- Low Supply Voltage:  $V_{CC} = 1.1$  to  $3.0\text{ Vdc}$
- Low Power Consumption:  $P_D = 1.5$  to  $5.0\text{ mW}$
- Input Bandwidth 75 MHz
- Excellent Sensitivity:  $0.5\ \mu\text{Vrms}$  for 12 dB SINAD
- Voltage Regulator Available (Source Capability 3.0 mA)
- Receiver Enable to Allow Active/Standby Operation
- Low Battery Detection Circuitry
- Self Biasing Audio Buffer
- Data Buffer
- FSK Data Shaping Comparator
- Standard 32-Lead QFP Surface Mount Package

Sleep-Mode is a trademark of Motorola, Inc.

**NOTES:**

1. FL1 and FL2 are 455 kHz ceramic bandpass filters, which should have input and output impedances of 1.5 k $\Omega$  to 2.0 k $\Omega$ . Suggested part numbers are MuRata CFU455X or CFW455x – the 'X' suffix denotes bandwidth.
2. LC1 is a 455 kHz LC resonator. Recommended part numbers are Toko America RMC2A6597HM or 5SVLC-0637BGT (smaller). The evaluation board layout shown provides for use of either resonator. Ceramic discriminator elements cannot be used with the MC3374 due to their low input impedance. The damping resistor value can be raised to increase the recovered audio or lowered to increase the quadrature detector's bandwidth and linearity – practical limits are approximately 27 k $\Omega$  to 75 k $\Omega$ . Typically the quadrature detector's bandwidth should match the low IF filter's bandwidth.
3. The data buffer is set up as a low-pass filter with a corner frequency of approximately 200 Hz. The audio buffer is a bandpass filter with corner frequencies of 300 Hz and 3.0 kHz. The audio amplifier provides bass suppression.
4.  $C_{C1}$  and  $C_{C3}$  are RF coupling capacitors and should have  $\leq 20 \Omega$  impedance at the desired input and oscillator frequencies.
5.  $C_{C2}$  provides "light coupling" of the oscillator signal into the mixer, and should have a 3.0 k $\Omega$  to 5.0 k $\Omega$  impedance at the desired local oscillator frequency.
6. Capacitors labelled  $C_B$  are bypass capacitors and should have 20  $\Omega$  impedance at the desired RF and local oscillator frequencies.
7. The network of L1, C1 and C2 provides impedance matching of the mixer input (nominally 3.0 k $\Omega$  shunted by 9.0 pF) to 50  $\Omega$  at the desired RF/IF input frequency. This will allow for bench testing of the receiver from typical RF signal generators or radio service monitors, but additional or different matching will be required to maximize receiver sensitivity when used in conjunction with an antenna, RF preamplifier or mixer.

**CIRCUIT DESCRIPTION**

The MC3374 is an FM narrowband receiver capable of operation to 75 MHz. The low voltage design yields low power drain and excellent sensitivity in narrowband voice and data link applications. In the typical application the mixer amplifies the incoming RF or IF signal and converts this frequency to 455 kHz. The signal is then filtered by a 455 kHz ceramic filter and applied to the first intermediate frequency (IF) amplifier input, before passing through a second ceramic filter. The modulated IF signal is then applied to the limiting IF amplifier and detector circuitry. Modulation is recovered by a conventional quadrature detector. The typical modulation bandwidth available is 3.0 to 5.0 kHz.

Features available include buffers for audio/data amplification and active filtering, on board voltage regulator, low battery detection circuitry with programmable level, and receiver disable circuitry. The MC3374 is an FM utility receiver to be used for voice and/or narrowband data reception. It is especially suitable where extremely low power consumption and high design flexibility are required.

**APPLICATION**

The MC3374 can be used as a high performance FM IF for the use in low power dual conversion receivers. Because of the MC3374's extremely good sensitivity (0.6 μV for 20 dB (S+N/N, see Figure 3)), it can also be used as a stand alone single conversion narrowband receiver to 75 MHz for applications not sensitive to image frequency interference. An RF preamplifier will likely be needed to overcome preselector losses.

The oscillator is a Colpitts type which must be run under crystal control. For fundamental mode crystals choose resonators, parallel resonant, for a 32 pF load. For higher frequencies, use a 3rd overtone series mode type. The coil L2 and RD resistor are needed to ensure proper operation.

The best adjacent channel and sensitivity response occur when two 455 kHz ceramic filters are used, as shown in Figure 1. Either can be replaced by a 0.1 μF coupling capacitor to reduce cost, but some degradation in sensitivity and/or stability is suspected.

The detector is a quadrature type, with the connection from the limiter output to the detector input provided internally. A 455 kHz LC tank circuit must be provided externally. One of the tank pins (Pin 8) must be decoupled using a 0.1 μF capacitor. The 56 kΩ damping resistor (see Figure 1), determines the peak separation of the detector (and thus its bandwidth). Smaller values will increase the separation and bandwidth but decrease recovered audio and sensitivity.

The data buffer is a noninverting amplifier with a nominal voltage gain of 2.7 V/V. This buffer needs its dc bias (approximately 250 mV) provided externally or else debiasing will occur. A 2nd order Sallen–Key low pass filter, as shown in Figure 1, connecting the recovered audio output to the data buffer input provides the necessary dc bias and some post detection filtering. The buffer can also be used as an active filter.

The audio buffer is a noninverting amplifier with a nominal voltage gain of 4.0 V/V. This buffer is self–biasing so its input should be ac coupled. The two buffers, when applied as active filters, can be used together to allow simultaneous audio and very low speed data reception. Another possible configuration is to receive audio only and include a noise–triggered squelch.

The comparator is a noninverting type with an open collector output. Typically, the pull–up resistor used between Pin 14 and V<sub>CC</sub> is 100 kΩ. With R<sub>L</sub> = 100 kΩ the comparator is capable of operation up to 25 kHz. The circuit is self–biasing, so its input should be ac coupled.

The regulator is a 1.07 V reference capable of sourcing 3.0 mA. This pin (Pin 17) needs to be decoupled using a 1.0–10 μF capacitor to maintain stability of the MC3374.

All three V<sub>CC</sub>s on the MC3374 (V<sub>CC</sub>, V<sub>CC2</sub>, V<sub>CC3</sub>) run on the same supply voltage. V<sub>CC</sub> is typically decoupled using capacitors only. V<sub>CC2</sub> and V<sub>CC3</sub> should be bypassed using the RC bypasses shown in Figure 1. Eliminating the resistors on the V<sub>CC2</sub> and V<sub>CC3</sub> bypasses may be possible in some applications, but a reduction in sensitivity and quieting will likely occur.

The low battery detection circuit gives an NPN open collector output at Pin 20 which drops low when the MC3374 supply voltage drops below 1.2 V. Typically it would be pulled up via a 100 kΩ resistor to supply.

The 1.2 V Select pin, when connected to the MC3374 supply, programs the low battery detector to trip at V<sub>CC</sub> < 1.1 V. Leaving this pin open raises the trip voltage on the low battery detector.

Pin 15 is a receiver enable which is connected to V<sub>CC</sub> for normal operation. Connecting this pin to ground shuts off receiver and reduces current drain to I<sub>CC</sub> < 0.5 μA.

**APPENDIX**

**Design of 2nd Order Sallen–Key Low Pass Filters**

The audio and data buffers can easily be configured as active low pass filters using the circuit configuration shown above. The circuit has a center frequency (f<sub>0</sub>) and quality factor (Q) given by the following:

$$f_0 = \frac{1}{2\pi \sqrt{R1R2C1C2}}$$

$$Q = \frac{1}{\sqrt{\frac{R2C2}{R1C1}} + \sqrt{\frac{R1C2}{R2C1}} + (1-K) \sqrt{\frac{R1C1}{R2C2}}}$$

If possible, let R1 = R2 or C1 = C2 to simplify the above equations. Be sure to avoid a negative Q value to prevent instability. Setting Q = 1/√2 = 0.707 yields a maximally flat filter response.

**Data Buffer Design**

The data buffer is designed as follows:

$$\begin{aligned} f_0 &= 200 \text{ Hz} \\ C1 = C2 &= 0.01 \text{ } \mu\text{F} \\ Q &= 0.707 \text{ (target)} \end{aligned}$$

K = 2.7 (data buffer open loop voltage gain)

Setting C1 = C2 yields:

$$f_0 = \frac{1}{2\pi C1 \sqrt{R1R2}}$$

$$Q = \frac{1}{\sqrt{\frac{R2}{R1}} + (2-K) \sqrt{\frac{R1}{R2}}}$$

Iteration yields R2 = 4.2 (R1) to make Q = 0.707.

Substitution into the equation for f<sub>0</sub> yields:

$$\begin{aligned} R1 &= 38 \text{ k}\Omega \text{ (use } 39 \text{ k}\Omega) \\ R2 &= 4.2(R1) = 180 \text{ k}\Omega \\ C1 = C2 &= 0.01 \text{ } \mu\text{F} \end{aligned}$$

**Audio Buffer Design**

The audio buffer is designed as follows:

$$\begin{aligned} f_0 &= 3000 \text{ Hz} \\ R1 = R2 &= 8.2 \text{ k}\Omega \\ Q &= 0.707 \text{ (target)} \end{aligned}$$

K = 3.9 (audio buffer open loop voltage gain)

Setting C1 = C2 yields:

$$f_0 = \frac{1}{2\pi R1 \sqrt{C1C2}}$$

$$Q = \frac{1}{\sqrt{\frac{C2}{C1}} + (1-K) \sqrt{\frac{C1}{C2}}}$$

Iteration yields C2 = 2.65 (C1) to make Q = 0.707.

Substitution into the equation for f<sub>0</sub> yields:

$$\begin{aligned} C1 &= 3900 \text{ pF} \\ C2 &= 2.65(C1) = 0.01 \text{ } \mu\text{F} \\ R1 = R2 &= 8.2 \text{ k}\Omega \end{aligned}$$

# MC13055

## Wideband FSK Receiver

The MC13055 is intended for RF data link systems using carrier frequencies up to 40 MHz and FSK (frequency shift keying) data rates up to 2.0 M Baud (1.0 MHz). This design is similar to the MC3356, except that it does not include the oscillator/mixer. The IF bandwidth has been increased and the detector output has been revised to a balanced configuration. The received signal strength metering circuit has been retained, as has the versatile data slicer/comparator.

- Input Sensitivity 20  $\mu$ V @ 40 MHz
- Signal Strength Indicator Linear Over 3 Decades
- Available in Surface Mount Package
- Easy Application, Few Peripheral Components

## MC13055

### GENERAL DESCRIPTION

The MC13055 is an extended frequency range FM IF, quadrature detector, signal strength detector and data shaper. It is intended primarily for FSK data systems. The design is very similar to MC3356 except that the oscillator/mixer has been removed, and the frequency capability of the IF has been raised about 2:1. The detector output configuration has been changed to a balanced, open-collector type to permit symmetrical drive of the data shaper (comparator). Meter drive and squelch features have been retained.

The limiting IF is a high frequency type, capable of being operated up to 100 MHz. It is expected to be used at 40 MHz in most cases. The quadrature detector is internally coupled to the IF, and a 2.0 pF quadrature capacitor is internally provided. The 20 dB quieting sensitivity is approximately 20  $\mu$ V, tuned input, and the IF can accept signals up to 220 mVrms without distortion or change of detector quiescent DC level.

The IF is unusual in that each of the last 5 stages of the 6 stage limiter contains a signal strength sensitive, current sinking device. These are parallel connected and buffered

to produce a signal strength meter drive which is fairly linear for IF input signals of 20  $\mu$ V to 20 mVrms (see Figure 4).

A simple squelch arrangement is provided whereby the meter current flowing through the meter load resistance flips a comparator at about 0.8 Vdc above ground. The signal strength at which this occurs can be adjusted by changing the meter load resistor. The comparator (+) input and output are available to permit control of hysteresis. Good positive action can be obtained for IF input signals of above 20  $\mu$ Vrms. A resistor (R) from Pin 13 to Pin 12 will provide  $V_{CC}/R$  of feedback current. This current can be correlated to an amount of signal strength hysteresis by using Figure 4.

The squelch is internally connected to the data shaper. Squelch causes the data shaper to produce a high ( $V_{CC}$ ) output.

The data shaper is a complete "floating" comparator, with diodes across its inputs. The outputs of the quadrature detector can be fed directly to either or preferably both inputs of the comparator to produce a squared output swinging from  $V_{CC}$  to ground in inverted or noninverted form.

**MOTOROLA**

# Universal Cordless Telephone Subsystem IC

The MC13109A integrates several of the functions required for a cordless telephone into a single integrated circuit. This significantly reduces component count, board space requirements, and external adjustments. It is designed for use in both the handset and the base.

- Dual Conversion FM Receiver
  - Complete Dual Conversion Receiver – Antenna Input to Audio Output  
80 MHz Maximum Carrier Frequency
  - RSSI Output
  - Carrier Detect Output with Programmable Threshold
  - Comparator for Data Recovery
  - Operates with Either a Quad Coil or Ceramic Discriminator
- Comander
  - Expander Includes Mute, Digital Volume Control and Speaker Driver
  - Compressor Includes Mute, ALC and Limiter
- Dual Universal Programmable PLL
  - Supports New 25 Channel U.S. Standard with No External Switches
  - Universal Design for Domestic and Foreign CT-0 Standards
  - Digitally Controlled Via a Serial Interface Port
  - Receive Side Includes 1st LO VCO, Phase Detector, and 14–Bit Programmable Counter and 2nd LO with 12–Bit Counter
  - Transmit Section Contains Phase Detector and 14–Bit Counter
  - MPU Clock Output Eliminates Need for MPU Crystal
- Supply Voltage Monitor
  - Externally Adjustable Trip Point
- 2.0 to 5.5 V Operation with One–Third the Power Consumption of Competing Devices

## MC13109A

### ELECTRICAL CHARACTERISTICS (continued)

#### Compressor/ALC/Tx Mute/Limiter

The compressor analog ground is set to the half supply reference so the input and output swing capability will increase as the supply voltage increases. The "C In" input is ac coupled. The ALC (Automatic Level Control) provides a soft limit to the output signal swing as the input voltage

increases slowly (i.e., a sine wave is maintained). The Limiter circuit limits rapidly changing signal levels by clipping the signal peaks. The ALC and/or Limiter can be disabled through the MPU serial interface.

(Test Conditions:  $V_{CC} = 2.6$  V,  $f_{in} = 1.0$  kHz,  $T_A = 25^\circ\text{C}$ .)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit

## ELECTRICAL CHARACTERISTICS (continued)

### Splatter Amplifier

The Splatter Amplifier is an inverting rail-to-rail output operational amplifier with the non-inverting input terminal connected to the internal  $V_B$  half supply reference. External

resistors and capacitors can be connected to set the gain and frequency response. The “Spl Amp In” input is ac coupled.

(Test Conditions:  $V_{CC} = 2.6$  V,  $T_A = 25^\circ\text{C}$ ,  $f_{in} = 1.0$  kHz, External resistors Set for Gain of 1.)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit
Open Loop Gain	–	Spl Amp In	Tx Out	$A_{VOL}$	–	60	–	dB
Gain Bandwidth	–	Spl Amp In	Tx Out	GBW	–	100	–	kHz
Maximum Output Swing	$R_L = 10$ k $\Omega$	Spl Amp In	Tx Out	$V_{Omax}$	–	$V_{CC} - 0.3$	–	$V_{pp}$

### Tx Audio Path Recommendation

The recommended configuration for the Tx Audio path includes setting the Microphone Amplifier gain to 16 dB using the external gain setting resistors and setting the Splatter Amplifier gain to 9.0 dB using the external gain setting resistors.

### PLL Voltage Regulator

The PLL supply voltage is regulated to a nominal of 2.2 V. The “ $V_{CC}$  Audio” pin is the supply voltage for the internal voltage regulator. The “PLL  $V_{ref}$ ” pin is the 2.2 V regulated output voltage. Two capacitors with 10  $\mu\text{F}$  and 0.01  $\mu\text{F}$  values must be connected to the “PLL  $V_{ref}$ ” pin to filter and stabilize this regulated voltage. The voltage regulator provides power for the 2nd LO, Rx and Tx PLL's, and MPU Interface. The voltage regulator can also be used to provide a regulated supply voltage for external IC's. Rx and Tx PLL loop

performance are independent of the power supply voltage when the voltage regulator is used. The voltage regulator requires about 200 mV of “headroom”. When the power supply decreases to within about 200 mV of the output voltage, the regulator will go out of regulation but the output voltage will not turn off. Instead, the output voltage will maintain about a 200 mV delta to the power supply voltage as the power supply voltage continues to decrease. The “PLL  $V_{ref}$ ” pin can be connected to “ $V_{CC}$  Audio” by the external wiring if voltage higher than 2.2 V is required. But it should not be connected to other supply except “ $V_{CC}$  Audio”. The voltage regulator is “on” in the Active and Rx modes. In the Standby and Inactive modes, the voltage regulator is turned off to reduce current drain and the “PLL  $V_{ref}$ ” pin is internally connected to “ $V_{CC}$  Audio” (i.e., the supply voltage is maintained but is now unregulated).

(Test Conditions:  $V_{CC} = 2.6$  V,  $T_A = 25^\circ\text{C}$ .)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit
Output Voltage Level	$V_{CC} = 2.6$ V, $I_L = 0$ mA	–	$V_{CC}$ PLL	$V_{out}$	–	2.2	–	V
Line Regulation	$I_L = 0$ mA, $V_{CC} = 2.6$ to 5.5 V	$V_{CC}$	$V_{CC}$ PLL	Reg <sub>line</sub>	–	3.66	40	mV
Load Regulation	$V_{CC} = 2.6$ V, $I_L = 0$ to 1.0 mA	$V_{CC}$	$V_{CC}$ PLL	Reg <sub>load</sub>	–40	–2.28	–	mV

# MC13109A

## ELECTRICAL CHARACTERISTICS (continued)

### Low Battery Detect

An external resistor divider is connected to the “Ref” input pin to set the threshold for the low battery detect. The voltage at the “Ref” input pin is compared to an internal 1.23 V

Bandgap reference voltage. The “BD Out” pin is open collector and requires an external pull-up resistor to  $V_{CC}$ .

(Test Conditions:  $V_{CC} = 2.6\text{ V}$ ,  $T_A = 25^\circ\text{C}$ .)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit

## PIN FUNCTION DESCRIPTION

48–TQFP Pin	52–QFP Pin	Symbol	Type	Description
1 2	1 2	LO <sub>2</sub> In LO <sub>2</sub> Out	–	These pins form the PLL reference oscillator when connected to an external parallel–resonant crystal (10.24 MHz typical). The reference oscillator is also the second Local Oscillator (LO <sub>2</sub> ) for the RF receiver.
3	3	PLL V <sub>ref</sub>	Supply	Voltage Regulator output pin. The internal voltage regulator provides a stable power supply voltage for the Rx and Tx PLL's and can also be used as a regulated supply voltage for the other IC's.
4	4	Rx PD	Output	Three state voltage output of the Rx Phase Detector. This pin is either “high”, “low”, or “high impedance” depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external Rx PLL loop filter. It is important to minimize the line length and capacitance of this pin.
5	5	Gnd PLL	Gnd	Ground pin for PLL section of IC.
6	6	Tx PD	Output	Three state voltage output of the Tx Phase Detector. This pin is either “high”, “low”, or “high impedance” depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external Tx PLL loop filter. It is important to minimize the line length and capacitance on this pin.
7	7	E Cap	–	Expander rectifier filter capacitor pin. Connect capacitor to V <sub>CC</sub> .
8	8	Tx VCO	Input	Transmit divide counter input which is driven by an ac coupled external transmit loop VCO. The minimum signal level is 200 mV <sub>pp</sub> @ 80.0 MHz. This pin also functions as the test mode input for the counter tests.
9 10 11	9 10 11	Data EN Clk	Input	Microprocessor serial interface input pins for programming various counters and control functions.
12	12	Clk Out	Output	Microprocessor Clock Output which is derived from the 2nd LO crystal oscillator and a programmable divider. It can be used to drive a microprocessor and thereby reduce the number of crystals required in the system design. The driver has an internal resistor in series with the output which can be combined with an external capacitor to form a low pass filter to reduce radiated noise on the PCB. This output also functions as the output for the counter test modes.
N/A	14	Status Out	Output	This pin indicates when the internal latches may have lost memory due to a power glitch.
13	15	CD Out/ Hardware Interrupt	Output/ Input	Dual function pin; 1) Carrier detect output (open collector with external 100 kΩ pull–up resistor. 2) Hardware interrupt input which can be used to “wake–up” from Inactive Mode.
14	16	BD Out	Output	Low battery detect output (open collector with external pull–up resistor).
15	17	DA Out	Output	Data amplifier output (open collector with internal 100 kΩ pull–up resistor).
16	18	SA Out	Output	Speaker amplifier output.
17	19	SA In	Input	Speaker amplifier input (ac coupled).
18	20	E Out	Output	Expander output.
19	21	V <sub>CC</sub> Audio	Supply	V <sub>CC</sub> supply for audio section.
20	22	DA In	Input	Data amplifier input (ac coupled).
21	23	Pre–Amp Out	Output	Pre–amplifier output for connection of pre–amplifier feedback resistor.
22	24	Rx Audio In	Input	Rx audio input to pre–amplifier (ac coupled).
23	25	Det Out	Output	Audio output from FM detector.
24	26	RSSI	–	Receive signal strength indicator filter capacitor.
N/A	27	N/A	–	Not used.
25	28	Q Coil	–	A quad coil or ceramic discriminator are connected to this pin.
26	29	V <sub>CC</sub> RF	Supply	V <sub>CC</sub> supply for RF receiver section.
27 28	30 31	Lim C2 Lim C1	–	IF amplifier/limiter capacitor pins.

# MC13109A

## PIN FUNCTION DESCRIPTION (continued)

48–TQFP Pin	52–QFP Pin	Symbol	Type	Description
29	32	Lim In	Input	Signal input for IF amplifier/limiter.
30	33	Gnd RF	Gnd	Ground pin for RF section of the IC.
31	34	Mix <sub>2</sub> Out	Output	Second mixer output.
32	35	Mix <sub>2</sub> In	Input	Second mixer input.
33	36	V <sub>B</sub>	–	Internal half supply analog ground reference.
34	37	Mix <sub>1</sub> Out	Output	First mixer output.
35	38	Mix <sub>1</sub> In <sub>2</sub>	Input	Negative polarity first mixer input.
36	39	Mix <sub>1</sub> In <sub>1</sub>	Input	Positive polarity first mixer input.
37 38	40 41	LO <sub>1</sub> In LO <sub>1</sub> Out	–	Tank elements for 1st LO multivibrator oscillator are connected to these pins.
39	42	V <sub>cap</sub> Ctrl	–	1st LO varactor control pin.
40	43	Gnd Audio	Gnd	Ground for audio section of the IC.
41	44	Tx In	Input	Tx path input to Microphone Amplifier (ac coupled).
42	45	Amp Out	Output	Microphone amplifier output.
43	46	C In	Input	Compressor input (ac coupled).
44	47	C Cap	–	Compressor rectifier filter capacitor pin. Connect capacitor to V <sub>CC</sub> .
45	48	Lim Out	Output	Tx path limiter output.
46	49	Spl Amp In	Input	Splatter amplifier input (ac coupled).
47	50	Tx Out	Output	Tx path audio output.
48	51	Ref	Input	Reference voltage input for low battery detect.
N/A	52	N/A	–	Not used.

### Power Supply Voltage

This circuit is used in a cordless telephone handset and base unit. The handset is battery powered and can operate on two or three NiCad cells or on 5.0 V power.

### PLL Frequency Synthesizer General Description

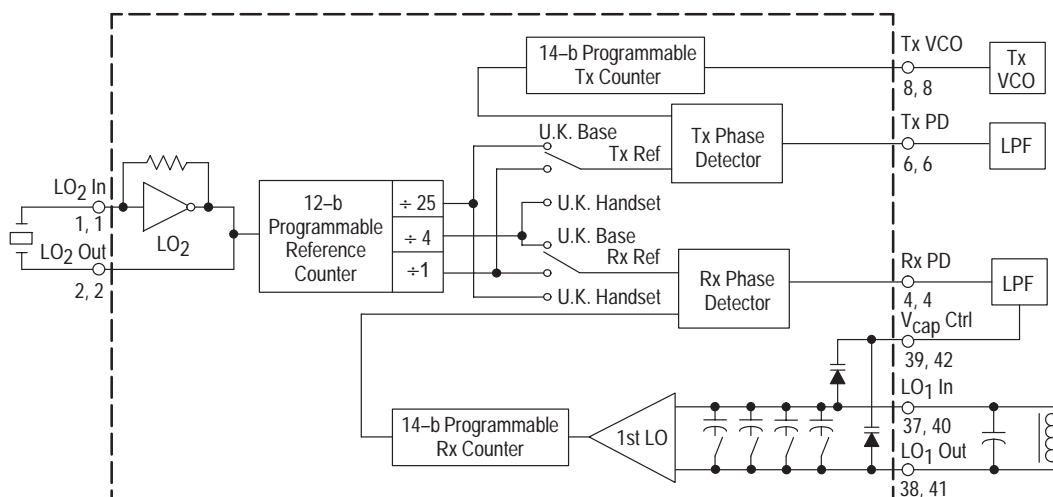

Figure 4 shows a simplified block diagram of the programmable universal dual phase locked loop (PLL). This dual PLL is fully programmable through the MCU serial interface and supports most country channel frequencies including USA (25 ch), France, Spain, Australia, Korea, New Zealand, U.K., Netherlands and China (see channel frequency tables in Appendix A).

The 2nd local oscillator and reference divider provide the reference frequency for the Rx and Tx PLL loops. The

programmed divider value for the reference divider is selected based on the crystal frequency and the desired Rx and Tx reference frequency values. Additional divide by 25 and divide by 4 blocks are provided to allow for generation of the 1.0 kHz and 6.25 kHz reference frequencies required for the U.K. The 14–Bit Tx counter is programmed for the desired transmit channel frequency. The 14–Bit Rx counter is programmed for the desired first local oscillator frequency. All counters power up in the proper default state for USA channel #6 and for a 10.24 MHz reference frequency crystal. Internal fixed capacitors can be connected to the tank circuit of the 1st LO through microprocessor control to extend the sensitivity of the 1st LO for U.S. 25 channel operation.

### PLL I/O Pin Specifications

The 2nd LO, Rx and Tx PLL's and MPU serial interface are normally powered by the internal voltage regulator at the “PLL  $V_{ref}$ ” pin. The “PLL  $V_{ref}$ ” pin is the output of a voltage regulator which is powered from the “ $V_{CC}$  Audio” power supply pin. Therefore, the maximum input and output levels for most PLL I/O pins (LO<sub>2</sub> In, LO<sub>2</sub> Out, Rx PD, Tx PD, Tx VCO) is the regulated voltage at the “PLL  $V_{ref}$ ” pin. The ESD protection diodes on these pins are also connected to “PLL  $V_{ref}$ ”. Internal level shift buffers are provided for the pins (Data, Clk, EN, Clk Out) which connect directly to the microprocessor. The maximum input and output levels for these pins is  $V_{CC}$ . Figure 5 shows a simplified schematic of the PLL I/O pins.

Figure 5. PLL I/O Pin Simplified Schematics

### Microprocessor Serial Interface

The “Data”, “Clk”, and “EN” pins provide an MPU serial interface for programming the reference counters, the transmit and receive channel divider counter and various control functions. The “Data” and “Clk” pins are used to load data into the shift register. Figure 6 shows “Data” and “Clk” pin timing. Data is clocked on positive clock transitions.

Figure 6. Data and Clock Timing Requirement

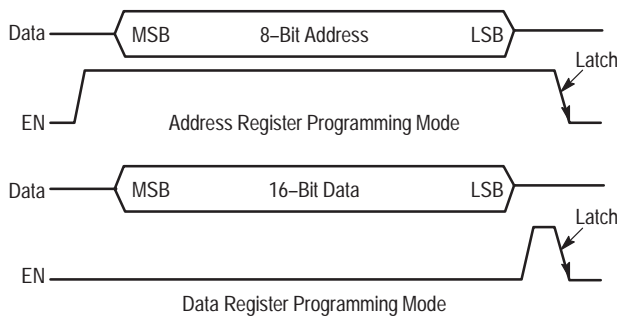

After data is loaded into the shift register, the data is latched into the appropriate latch register using the “EN” pin. This is done in two steps. First, an 8–Bit address is loaded into the shift register and latched into the 8–Bit address latch register. Then, up to 16–Bits of data is loaded into the shift register and latched into the data latch register specified by the address that was previously loaded. Figure 7 shows the timing required on the EN pin. Latching occurs on the negative EN transition.

Figure 7. Enable Timing Requirement

The state of the EN pin when clocking data into the shift register determines whether the data is latched into the address register or a data register. Figure 8 shows the address and data programming diagrams. In the data programming mode, there must not be any clock transitions when “EN” is high. The clock can be in a high state (default high) or a low state (default low) but must not have any transitions during the “EN” high state. The convention in these figures is that latch bits to the left are loaded into the shift register first.

Figure 8. Microprocessor Interface Programming Mode Diagrams

The MPU serial interface is fully operational within 100  $\mu$ s after the power supply has reached its minimum level during power-up (See Figure 9). The MPU Interface shift registers and data latches are operational in all four power saving

modes; Inactive, Standby, Rx, and Active Modes. Data can be loaded into the shift registers and latched into the latch registers in any of the operating modes.

Figure 9. Microprocessor Serial Interface Power-Up Delay

**Status Out**

This is a digital output which indicates whether the latch registers have been reset to their power-up default values. Latch power-up default values are given in Figure 28. If there is a power glitch or ESD event which causes the latch registers to be reset to their default values, the “Status Out” pin will indicate this to the MPU so it can reload the correct information into the latch registers.

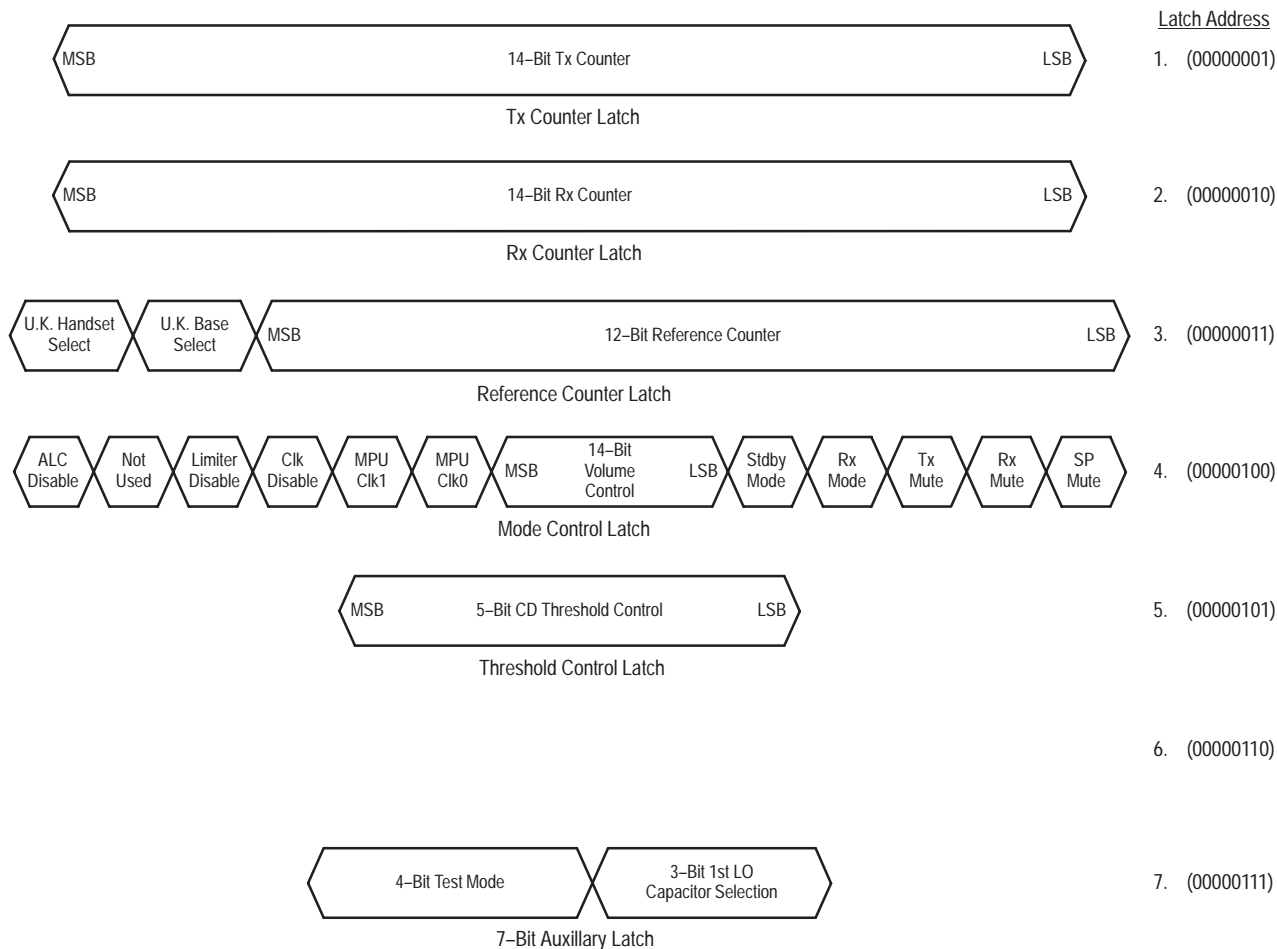

Figure 10. Status Out Operation

Status Latch Register Bits	Status Out Logic Level
Latch bits not at power-up default value	0
Latch bits at power-up default value	1

**Data Registers**

Figure 11 shows the data latch registers and addresses which are used to select each of these registers. Latch bits to the left (MSB) are loaded into the shift register first. The LSB bit must always be the last bit loaded into the shift register. “Don’t Care” bits can be loaded into the shift register first if 8-Bit bytes of data are loaded.

Figure 11. Microprocessor Interface Data Latch Registers

**Reference Frequency Selection**

The “LO<sub>2</sub> In” and “LO<sub>2</sub> Out” pins form a reference oscillator when connected to an external parallel-resonant crystal. The reference oscillator is also the second local oscillator for the RF Receiver. Figure 12 shows the relationship between different crystal frequencies and reference frequencies for cordless phone applications in various countries.

Figure 12. Reference Frequency and Reference Divider Values

Crystal Frequency	Reference Divider Value	U.K. Base/ Handset Divider	Reference Frequency
10.24 MHz	2048	1	5.0 kHz
10.24 MHz	1024	4	2.5 kHz
11.15 MHz	2230	1	5.0 kHz
12.00 MHz	2400	1	5.0 kHz
11.15 MHz	1784	1	6.25 kHz
11.15 MHz	446	4	6.25 kHz
11.15 MHz	446	25	1.0 kHz

**Reference Counter**

Figure 14 shows how the reference frequencies for the Rx and Tx loops are generated. All countries except U.K. require that the Tx and Rx reference frequencies be identical. In this case, set “U.K. Base Select” and “U.K. Handset Select” bits to “0”. Then the fixed divider is set to “1” and the Tx and Rx reference frequencies will be equal to the crystal oscillator frequency divided by the programmable reference counter value. The U.K. is a special case which requires a different reference frequency value of Tx and Rx.

For U.K. base operation, set “U.K. Base Select” to “1”. For U.K. handset operation, set “U.K. Handset Select” to “1”. The Netherlands is also a special case since a 2.5 kHz reference frequency is used for both the Tx and Rx reference and the total divider value required is 4096 which is larger than the maximum divide value available from the 12-Bit reference divider (4095). In this case, set “U.K. Base Select” to “1” and set “U.K. Handset Select” to “1”. This will give a fixed divide by 4 for both the Tx and Rx reference. Then set the reference divider to 1024 to get a total divider of 4096.

**Mode Control Register**

Power saving modes, mutes, disables, volume control, and microprocessor clock output frequency are all set by the Control Register. Operation of the Control Register is explained in Figures 15 through 21.

# MC13109A

**Figure 13. Reference Register Programming Mode**

### Power Saving Operating Modes

When the MC13109A is used in a handset, it is important to conserve power in order to prolong battery life. There are five modes of operation; Active, Rx, Standby, Interrupt and Inactive. In Active Mode, all circuit blocks are powered. In Rx mode, all circuitry is powered down except for those circuit

sections needed to receive a transmission from the base. In the Standby and Interrupt Modes, all circuitry is powered down except for the circuitry needed to provide the clock output for the microprocessor. In Inactive Mode, all circuitry is powered down except the MPU interface. Latch memory is maintained in all modes. Figure 17 shows the control register bit values for selection of each power saving mode and Figure 18 show the circuit blocks which are powered in each of these operating mode.

**Figure 16. Power Saving Mode Selection**

Stdby Mode Bit	Rx Mode Bit	"CD Out/Hardware Interrupt" Pin	Power Saving Mode
0	0	X	Active
0	1	X	Rx
1	0	X	Standby
1	1	1 or High Impedance	Inactive
1	1	0	Inactive

**NOTE:** 1. In Standby and Inactive Modes, "PLL V<sub>ref</sub>" remains powered but is not regulated. It will fluctuate with V<sub>CC</sub>.

## Inactive Mode Operation and Hardware Interrupt

In some handset applications it may be desirable to power down all circuitry including the microprocessor (MPU). First put the MC13109A into the Inactive mode, which turns off the MPU Clock Output (see Figure 21), and then disable the microprocessor. In order to give the MPU adequate time to power down, the MPU Clock output remains active for a minimum of one reference counter cycle (about 200 μs) after the command is given to switch into the "Inactive" mode. An external timing circuit should be used to initiate the turn-on sequence. The "CD Out" pin has a dual function. In the Active and Rx modes it performs the carrier detect function. In the

Standby and Inactive modes the carrier detect circuit is disabled and the "CD Out" pin is in a "High" state due to the external pull-up resistor. In the Inactive mode the "CD Out" pin is the input for the hardware interrupt function. When the "CD Out" pin is pulled "low" by the external timing circuit, the MC13109A switches from the Inactive to the Interrupt mode thereby turning on the MPU Clock Output. The MPU can then resume control of the combo IC. The "CD Out" pin must remain low until the MPU changes the operating mode from Interrupt to Standby, Active or Rx modes.

Figure 18. Hardware Interrupt Operation

# MC13109A

## “Clk Out” Divider Programming

The “Clk Out” pin is derived from the 2nd local oscillator and can be used to drive a microprocessor, thereby reducing the number of crystals required. Figure 22 shows the relationship between the crystal frequency and the clock output for different divider values. Figure 20 shows the “Clk Out” register bit values.

**Figure 19. Clock Output Values**

Crystal Frequency	Clock Output Divider			
	2	3	5	10
10.24 MHz	5.120 MHz	3.413 MHz	2.048 MHz	1.024 MHz
11.15 MHz	5.575 MHz	3.717 MHz	2.230 MHz	1.115 MHz
12.00 MHz	6.000 MHz	4.000 MHz	2.400 MHz	1.200 MHz

**Figure 20. Clock Output Divider**

Clk Out Bit #1	Clk Out Bit #2	Clk Out Divider Value
0	0	2
0	1	3
1	0	5
1	1	10

## MPU “Clk Out” Power-Up Default Divider Value

The power-up default divider value is “divide by 10”. This provides an MPU clock of about 1.0 MHz after initial power-up. The reason for choosing this relatively low clock frequency after initial power-up is that some microprocessors that operate down to a 2.0 V power supply have a maximum clock frequency of 1.0 MHz. After initial power-up, the MPU can change the clock divider value to set the clock to the desired operating frequency. Special care has been taken in the design of the clock divider to ensure that the transition between one clock divider value and another is “smooth” (i.e., there will be no narrow clock pulses to disturb the MPU).

## MPU “Clk Out” Radiated Noise on Circuit Board

The clock line running between the MC13109A and the microprocessor has the potential to radiate noise which can cause problems in the system especially if the clock is a square wave digital signal with large high frequency harmonics. In order to minimize radiated noise, a 1.0 kΩ resistor is included on-chip in-series with the “Clk Out” output driver. A small capacitor can be connected to the “Clk Out” line on the PCB to form a single pole low pass filter. This filter will significantly reduce noise radiated from the “Clk Out” line.

## Volume Control

The volume control can be programmed in 2.0 dB gain steps from -14 dB to 16 dB. The power-up default value is 0 dB.

**Figure 21. Volume Control**

Volume Control Bit #3	Volume Control Bit #2	Volume Control Bit #1	Volume Control Bit #0	Volume Control #	Gain/Attenuation Amount

## Gain Control Register

The gain control register contains bits which control the Carrier Detect threshold. Operation of these latch bits are explained in Figures 22 and 23.

**Figure 22. Gain Control Latch Bits**

## MC13109A

### Carrier Detect Threshold Programming

The "CD Out" pin will give an indication to the microprocessor if a carrier signal is present on the selected channel. The nominal value and tolerance of the carrier

detect threshold is given in the carrier detect specification section of this document. If a different carrier detect threshold value is desired, it can be set through the MPU interface as shown in Figure 23 below.

# MC13109A

## Auxiliary Register

The auxiliary register contains a 3-Bit 1st LO Capacitor Selection latch and a 4-Bit Test Mode latch. Operation of these latch bits are explained in Figures 24, 25 and 26.

Figure 24. Auxiliary Register Latch Bits

## First Local Oscillator Capacitor Selection for 25 Channel U.S. Operation

There is a very large frequency difference between the minimum and maximum channel frequencies in the proposed 25 Channel U.S. standard. The sensitivity of the 1st LO is not large enough to accommodate this large frequency variation. Fixed capacitors can be connected across the 1st LO tank

circuit to change the 1st LO sensitivity. Internal switches and capacitors are provided to enable microprocessor control over internal fixed capacitor values. Figure 25 shows the schematic of the 1st LO tank circuit. Figure 26 shows the latch control bit values.

Figure 25. First LO Schematic

Figure 27. Test Mode Description

TM #	TM 3	TM 2	TM 1	TM 0	Counter Under Test or Test Mode Option	“Tx VCO” Input Signal	“Clk Out” Output Expected
0	0	0	0	0	Normal Operation	>200 mVpp	–
1	0	0	0	1	Rx Counter, upper 6	0 to 2.2 V	Input Frequency/64
2	0	0	1	0	Rx Counter, lower 8	0 to 2.2 V	See Note Below
3	0	0	1	1	Rx Prescaler	0 to 2.2 V	Input Frequency/4
4	0	1	0	0	Tx Counter, upper 6	0 to 2.2 V	Input Frequency/64
5	0	1	0	1	Tx Counter, lower 8	0 to 2.2 V	See Note Below
6	0	1	1	0	Tx Prescaler	>200 mVpp	Input Frequency/4
7	0	1	1	1	Reference Counter	0 to 2.2 V	Input Frequency/Reference Counter Value
8	1	0	0	0	Divide by 4, 25	0 to 2.2 V	Input Frequency/100
9	1	0	0	1	AGC Gain = 10 Option	N/A	–
10	1	0	1	0	AGC Gain = 25 Option	N/A	–

**NOTE:** To determine the correct output, look at the lower 8 bits in the Rx or Tx register (Divisor (7;0). If the value of the divisor is > 16, then the output divisor value is Divisor (7;2) (the upper 6 bits of the divisor). If Divisor (7;0) < 16 and Divisor (3;2) > = 2, then output divisor value is Divisor (3;2) (bits 2 and 3 of the divisor). If Divisor (7;0) < 16 and Divisor (3;2) < 2, then output divisor value is (Divisor (3;2) + 60).

## Test Modes

Test Mode Control latch bits enable independent testing of internal counters and set AGC Gain Options. In test mode, the “Tx VCO” input pin is multiplexed to the input of the counter under test and the output of the counter under test is multiplexed to the “Clk Out” output pin so that each counter can be individually tested. Make sure test mode bits are set to “0” for normal operation. Test mode operation is described in Figure 27. During normal operation and when testing the Tx Prescaler, the “Tx VCO” input can be a minimum of 200 mVpp at 80 MHz and should be ac coupled. For other test modes, input signals should be standard logic levels of 0 to 2.2 V and a maximum frequency of 16 MHz.

## Power-Up Defaults for Control and Counter Registers

When the IC is first powered up, all latch registers are initialized to a defined state. The MC13109A is initially placed in the Rx mode with all mutes active and nothing disabled. The reference counter is set to generate a 5.0 kHz reference frequency from a 10.24 MHz crystal. The MPU clock output divider is set to 10 to give the minimum clock output frequency. The Tx and Rx latch registers are set for USA Channel Frequency #21. Figure 28 shows the initial power-up states for all latch registers.

## APPENDIX A – MEASUREMENT OF COMPANDOR ATTACK/DECAY TIME

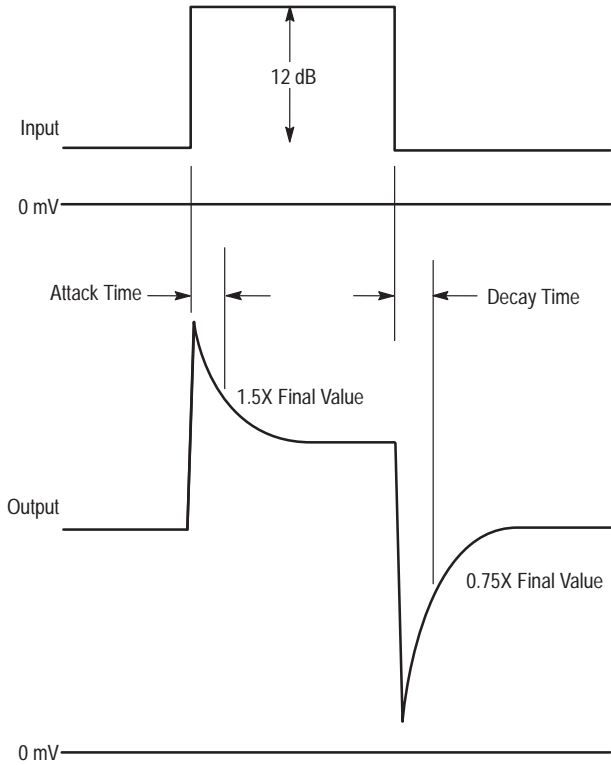

This measurement definition is based on EIA/CCITT recommendations.

### Compressor Attack Time

For a 12 dB step up at the input, attack time is defined as the time for the output to settle to 1.5X of the final steady state value.

### Compressor Decay Time

For a 12 dB step down at the input, decay time is defined as the time for the input to settle to 0.75X of the final steady state value.

### Expander Attack

For a 6.0 dB step up at the input, attack time is defined as the time for the output to settle to 0.57X of the final steady state value.

### Expander Decay

For a 6.0 dB step down at the input, decay time is defined as the time for the output to settle to 1.5X of the final steady state value.

**MOTOROLA**

# Universal Cordless Telephone Subsystem IC

The MC13110A and MC13111A integrates several of the functions required for a cordless telephone into a single integrated circuit. This significantly reduces component count, board space requirements, external adjustments, and lowers overall costs. It is designed for use in both the handset and the base.

- Fully Programmable in all Power Modes
- Dual Conversion FM Receiver
  - Complete Dual Conversion Receiver – Antenna Input to Audio Out
  - 80 MHz Maximum Carrier Frequency
  - RSSI Output
  - Carrier Detect Output with Programmable Threshold
  - Comparator for Data Recovery
  - Operates with Either a Quad Coil or Ceramic Discriminator
- Compander
  - Expander Includes Mute, Digital Volume Control, Speaker Driver, Programmable Low Pass Filter, and Gain Block
  - Compressor Includes Mute, Programmable Low Pass Filter, Limiter, and Gain Block
- MC13110A only: Frequency Inversion Scrambler
  - Function Controlled via MPU Interface
  - Programmable Carrier Modulation Frequency
- Dual Universal Programmable PLL
  - Supports New 25 Channel U.S. Standard with No External Switches
  - Universal Design for Domestic and Foreign Cordless Telephone Standards
  - Digitally Controlled Via a Serial Interface Port
  - Receive Side Includes 1st LO VCO, Phase Detector, and 14–Bit Programmable Counter and 2nd LO with 12–Bit Counter
  - Transmit Section Contains Phase Detector and 14–Bit Counter
  - MPU Clock Outputs Eliminates Need for MPU Crystal
- Low Battery Detect
  - Provides Two Levels of Monitoring with Separate Outputs
  - Separate, Adjustable Trip Points
- 2.7 to 5.5 V Operation (15  $\mu$ A Current Consumption in Inactive Mode)
- AN1575: Refer to this Application Note for a List of the “Worldwide Cordless Telephone Frequencies

## PIN FUNCTION DESCRIPTION

Pin		Symbol/ Type	Equivalent Internal Circuit (52 Pin QFP)	Description
LQFP-48	QFP-52			
48 1	1 2	LO <sub>2</sub> In LO <sub>2</sub> Out		<p>These pins form the PLL reference oscillator when connected to an external parallel-resonant crystal (10.24 MHz typical). The reference oscillator is also the second Local Oscillator (LO<sub>2</sub>) for the RF receiver. "LO<sub>2</sub> In" may also serve as an input for an externally generated reference signal which is typically ac-coupled.</p> <p>When the IC is set to the inactive mode, LO<sub>2</sub> In is internally pulled low to disable the oscillator. The input capacitance to ground at each pin (LO<sub>2</sub> In/ LO<sub>2</sub> Out) is 3.0 pF.</p>
2	3	V <sub>ag</sub>		V <sub>ag</sub> is the internal reference voltage for the switched capacitor filter section. This pin must be decoupled with a 0.1 μF capacitor.
3	4	R <sub>X</sub> PD (Output)		This pin is a tri-state voltage output of the R <sub>X</sub> and T <sub>X</sub> Phase Detector. It is either "high", "low", or "high impedance," depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external R <sub>X</sub> and T <sub>X</sub> PLL loop filters. R <sub>X</sub> and T <sub>X</sub> PD outputs can sink or source 1.0 mA.
5	6	T <sub>X</sub> PD (Output)		
4	5	PLL V <sub>ref</sub>		PLL V <sub>ref</sub> is a PLL voltage regulator output pin. An internal voltage regulator provides a stable power supply voltage for the R <sub>X</sub> and T <sub>X</sub> PLL's and can also be used as a regulated supply voltage for other IC's. It can source up to 1.0 mA externally. Proper supply filtering is a must on this pin. PLL V <sub>ref</sub> is pulled up to V <sub>CC</sub> audio for the standby and inactive modes (Note 1).
6	7	Gnd PLL		Ground pin for digital PLL section of IC.
7	8	T <sub>X</sub> VCO (Input)		T <sub>X</sub> VCO is the transmit divide counter input which is driven by an ac-coupled external transmit loop VCO. The minimum signal level is 200 mVpp @ 60.0 MHz. This pin also functions as the test mode input for the counter tests.

# MC13110A MC13111A

## PIN FUNCTION DESCRIPTION (continued)

Pin		Symbol/ Type	Equivalent Internal Circuit (52 Pin QFP)	Description
LQFP-48	QFP-52			
8 9 10	9 10 11	Data EN Clk (Input)		Microprocessor serial interface input pins are for programming various counters and control functions. The switching thresholds are referenced to PLL $V_{ref}$ and Gnd PLL. The inputs operate up to $V_{CC}$ . These pins have $1.0 \mu\text{A}$ internal pull-down currents.
11	12	Clk Out (Output)		The microprocessor clock output is derived from the 2nd LO crystal oscillator and a programmable divider with divide ratios of 2 to 312.5. It can be used to drive a microprocessor and thereby reduce the number of crystals required in the system design. The driver has an internal resistor in series with the output which can be combined with an external capacitor to form a low pass filter to reduce radiated noise on the PCB. This output also functions as the output for the counter test modes. The Clk Out can be disabled via the MPU interface.
12	13	CD Out (I/O)		Dual function pin; 1) Carrier detect output (open collector with external $100 \text{ k}\Omega$ pull-up resistor). 2) Hardware interrupt input which can be used to "wake-up" from the Inactive Mode.
-	14	BD <sub>1</sub> Out		Low battery detect output #1 is an open collector with external pull-up resistor.
14	16	BD <sub>2</sub> Out (Output)		Low battery detect output #2 is an open collector with external pull-up resistor.
13	15	DA Out (Output)		Data amplifier output (open collector with internal $100 \text{ k}\Omega$ pull-up resistor).
15	17	T <sub>x</sub> Out (Output)		T <sub>x</sub> Out is the T <sub>x</sub> path audio output. Internally this pin has a low-pass filter circuitry with -3 dB bandwidth of 4.0 kHz. T <sub>x</sub> gain and mute are programmable through the MPU interface. This pin is sensitive to load capacitance.

# MC13110A MC13111A

## PIN FUNCTION DESCRIPTION (continued)

Pin		Symbol/ Type	Equivalent Internal Circuit (52 Pin QFP)	Description
LQFP-48	QFP-52			
16	18	C Cap		C Cap is the compressor rectifier filter capacitor pin. It is recommended that an external filter capacitor to $V_{CC}$ audio be used. A practical capacitor range is 0.1 to 1.0 $\mu\text{F}$ . 0.47 $\mu\text{F}$ is the recommended value.
17	19	C In (Input)		C In is the compressor input. This pin is internally biased and has an input impedance of 12.5 k. C In must be ac-coupled.
18	20	Amp Out (Output)		Microphone amplifier output. The gain is set with external resistors. The feedback resistor should be less than 200 k $\Omega$ .
19	21	T <sub>x</sub> In (Input)		T <sub>x</sub> In is the T <sub>x</sub> path input to the microphone amplifier (Mic Amp). An external resistor is connected to this pin to set the Mic Amp gain and input impedance. T <sub>x</sub> In must be ac-coupled, too.
20	22	DA In (Input)		The data amplifier input (DA In) resistance is 250 k $\Omega$ and must be ac-coupled. Hysteresis is internally provided.
21	23	V <sub>CC</sub> Audio		V <sub>CC</sub> audio is the supply for the audio section. It is necessary to adequately filter this pin.
22	24	R <sub>x</sub> Audio In (Input)		The R <sub>x</sub> audio input resistance is 600 k $\Omega$ and must be ac-coupled.
23	25	Det Out (Output)		Det Out is the audio output from the FM detector. This pin is dc-coupled from the FM detector and has an output impedance of 1100 $\Omega$ .

# MC13110A MC13111A

## PIN FUNCTION DESCRIPTION (continued)

Pin		Symbol/ Type	Equivalent Internal Circuit (52 Pin QFP)	Description
LQFP-48	QFP-52			
30	26	RSSI		RSSI is the receive signal strength indicator. This pin must be filtered through a capacitor to ground. The capacitance value range should be 0.01 to 0.1 $\mu$ F. This is also the input to the Carrier Detect comparator. An external R to ground shifts the RSSI voltage.
24	27	Q Coil		A quad coil or ceramic discriminator connects this pin as part of the FM demodulator circuit. DC-couple this pin to $V_{CC}$ RF through the quad coil or the external resistor.
26	29	$V_{CC}$ RF		$V_{CC}$ supply for RF receiver section (1st LO, mixer, limiter, demodulator). Proper supply filtering is needed on this pin too.
25	28	Lim Out		A quad coil or ceramic discriminator are connected to these pins as part of the FM demodulator circuit. A coupling capacitor connects this pin to the quad coil or ceramic discriminator as part of the FM demodulator circuit. This pin can drive coupling capacitors up to 47 pF with no deterioration in performance.
27 28	30 31	Lim C <sub>2</sub> Lim C <sub>1</sub>		IF amplifier/limiter capacitor pins. These decoupling capacitors should be 0.1 $\mu$ F. They determine the IF limiter gain and low frequency bandwidth.
29	32	Lim In (Input)		Signal input for IF amplifier/limiter. Signals should be ac-coupled to this pin. The input impedance is 1.5 k $\Omega$ at 455 kHz.
-	33	SGnd RF		This pin is not connected internally but should be grounded to reduce potential coupling between pins.
31	34	Mix <sub>2</sub> In (Input)		Mix <sub>2</sub> In is the second mixer input. Signals are to be ac-coupled to this pin, which is biased internally to $V_{CC}$ RF. The input impedance is 2.8 k $\Omega$ at 455 kHz. The input impedance can be reduced by connecting an external resistor to $V_{CC}$ RF.

## PIN FUNCTION DESCRIPTION (continued)

Pin		Symbol/ Type	Equivalent Internal Circuit (52 Pin QFP)	Description
LQFP-48	QFP-52			
32	35	Mix <sub>2</sub> Out (Output)		Mix <sub>2</sub> Out is the second mixer output. The second mixer has a 3 dB bandwidth of 2.5 MHz and an output impedance of 1.5 kΩ. The output current drive is 50 μA.
33	36	Gnd RF		Ground pin for RF section of the IC.
34	37	Mix <sub>1</sub> Out (Output)		The first mixer has a 3 dB IF bandwidth of 13 MHz and an output impedance of 300 Ω. The output current drive is 300 μA and can be programmed for 1.0 mA.
35	38	Mix <sub>1</sub> In <sub>2</sub> (Input)		Signals should be ac-coupled to this pin, which is biased internally to V <sub>CC</sub> - 1.6 V. The single-ended and differential input impedance are about 1.6 and 1.8 kΩ at 46 MHz, respectively.
36	39	Mix <sub>1</sub> In <sub>1</sub> (Input)		
37 38	40 41	LO <sub>1</sub> In LO <sub>1</sub> Out		Tank Elements, an internal varactor and capacitor matrix for 1st LO multivibrator oscillator are connected to these pins. The oscillator is useable up to 80 MHz.
39	42	V <sub>cap</sub> Ctrl		V <sub>cap</sub> Ctrl is the 1st LO varactor control pin. The voltage at this pin is referenced to Gnd Audio and varies the capacitance between LO <sub>1</sub> In and LO <sub>2</sub> Out. An increase in voltage will decrease capacitance.
40	43	Gnd Audio		Ground for audio section of the IC.
41	44	SA Out (Output)		The speaker amplifier gain is set with an external feedback resistor. It should be less than 200 kΩ. The speaker amplifier can be muted through the MPU interface.
42	45	SA In (Input)		An external resistor is connected to the speaker amplifier input (SA In). This will set the gain and input impedance and must be ac-coupled.

# MC13110A MC13111A

## PIN FUNCTION DESCRIPTION (continued)

Pin		Symbol/ Type	Equivalent Internal Circuit (52 Pin QFP)	Description
LQFP-48	QFP-52			
43	46	E Out (Output)		The output level of the expander output is determined by the volume control. Volume control is programmable through the MPU interface.
44	47	E Cap		E Cap is the expander rectifier filter capacitor pin. Connect an external filter capacitor between V <sub>CC</sub> audio and E Cap. The recommended capacitance range is 0.1 to 1.0 μF. 0.47 μF is the suggested value.
45	48	E In (Input)		The expander input pin is internally biased and has input impedance of 30 kΩ.
46	49	Scr Out (Output)		Scr Out is the R <sub>x</sub> audio output. An internal low pass filter has a -3 dB bandwidth of 4.0 kHz.
-	50	Ref <sub>2</sub>		Reference voltage input for Low Battery Detect #2.
-	51	Ref <sub>1</sub>		Reference voltage input for Low Battery Detect #1.
47	52	V <sub>B</sub>		V <sub>B</sub> is the internal half supply analog ground reference. This pin must be filtered with a capacitor to ground. A typical capacitor range of 0.5 to 10 μF is desired to reduce crosstalk and noise. It is important to keep this capacitor value equal to the PLL V <sub>ref</sub> capacitor due to logic timing (Note 9).

**NOTE:** 9. A capacitor range of 0.5 to 10 μF is recommended. The capacitor value should be the same used on the V<sub>B</sub> pin (Pin 52). An additional high quality parallel capacitor of 0.01 μF is essential to filter out spikes originating from the PLL logic circuitry.

## DEVICE DESCRIPTION AND APPLICATION INFORMATION

The following text, graphics, tables and schematics are provided to the user as a source of valuable technical information about the Universal Cordless Telephone IC. This information originates from thorough evaluation of the device performance for the US and French applications. This data was obtained by using units from typical wafer lots. It is important to note that the forgoing data and information was from a limited number of units. By no means is the user to assume that the data following is a guaranteed parametric. Only the minimum and maximum limits identified in the electrical characteristics tables found earlier in this spec are guaranteed.

### General Circuit Description

The MC13110A and MC13111A are a low power dual conversion narrowband FM receiver designed for applications up to 80 MHz carrier frequency. This device is primarily designated to be used for the 49 MHz cordless phone (CT-0), but has other applications such as low data rate narrowband data links and as a backend device for 900 MHz systems where baseband analog processing is required. This device contains a first and second mixer, limiter, demodulator, extended range receive signal strength (RSSI), receive and transmit baseband processing, dual programmable PLL, low battery detect, and serial interface for microprocessor control. The FM receiver can also be used with either a quadrature coil or ceramic resonator. Refer to the Pin Function Description table for the simplified internal circuit schematic and description of this device.

### DC Current and Battery Detect

Figures 3 through 6 are the current consumption for Inactive, Standby, Receive, and Active modes versus supply voltages. Figures 7 and 8 show the typical behavior of current consumption in relation to temperature. The relationship of additional current draw due to IP3 bit set to <1> and supply voltage are shown in Figures 9 and 10.

For the Low Battery Detect, the user has the option to operate the IC in the programmable or non-programmable modes. Note that the 48 pin package can only be used in the programmable mode. Figure 127 describes this operation (refer to the Serial Interface section under Clock Divider Register).

In the programmable mode several different internal threshold levels are available (Figure 2). The bits are set through the SCF Clock Divider Register as shown in Figures 108 and 125. The reference for the internal divider network is  $V_{CC}$  Audio. The voltages on the internal divider network are compared to the Internal Reference Voltage, VB, generated by an internal source. Since the internal comparator used is non-inverting, a high at  $V_{CC}$  Audio will yield a high at the

battery detect output, and vice versa for  $V_{CC}$  Audio set to a low level. For the 52 pin package option, the Ref 1 and Ref 2 pins need to be tied to  $V_{CC}$  when used in the programmable mode. It is essential to keep the external reference pins above Gnd to prevent any possible power-on reset to be activated.

When considering the non-programmable mode (bits set to <000>) for the 52 pin package, the Ref 1 and Ref 2 pins become the comparators reference. An internal switch is activated when the non-programmable mode is chosen connecting Ref 1 and Ref 2. Here, two external precision resistor dividers are used to set independent thresholds for two battery detect hysteresis comparators. The voltages on Ref 1 and Ref 2 are again compared to the internally generated 1.5 V reference voltage (VB).

The Low Battery Detect threshold tolerance can be improved by adjusting a trim-pot in the external resistor divider (user designed). The initial tolerance of the internal reference voltage (VB) is  $\pm 6.0\%$ . Alternately, the tolerance of the internal reference voltage can be improved to  $\pm 1.5\%$  through MPU serial interface programming (refer to the Serial Interface section, Figure 130). The internal reference can be measured directly at the "VB" pin. During final test of the telephone, the VB internal reference voltage is measured. Then, the internal reference voltage value is adjusted electronically through the MPU serial interface to achieve the desired accuracy level. The voltage reference register value should be stored in ROM during final test so that it can be reloaded each time the combo IC is powered up. The Low Battery Detect outputs are open collector. The battery detect levels will depend on the accuracy of the VB voltage. Figure 12 indicates that the VB voltage is fairly flat over temperature.

**Figure 2. Internal Low Battery Detect Levels  
(with VB = 1.5 V)**

Battery Detect Select	Ramping Up (V)	Ramping Down (V)	Average (V)	Hysteresis (mV)
0	–	–	–	–

## FIRST AND SECOND MIXER

### Mixer Description

The 1st and 2nd mixers are similar in design. Both are double balanced to suppress the LO and the input frequencies to give only the sum and difference frequencies at the mixer output. Typically the LO is suppressed better than  $-50$  dB for the first mixer and better than  $-40$  dB for the second mixer. The gain of the 1st mixer has a  $-3.0$  dB corner at approximately 13 MHz and is used at a 10.7 MHz IF. It has an output impedance of  $300 \Omega$  and matches to a typical 10.7 MHz ceramic filter with a source and load impedance of  $330 \Omega$ . A series resistor may be used to raise the impedance for use with crystal filters. They typically have an input impedance much greater than  $330 \Omega$ .

### First Mixer

Figures 17 through 20 show the first mixer transfer curves for the voltage conversion gain, output level, and intermodulation. Notice that there is approximately 10 dB linearity improvement when the "IP3 Increase" bit is set to  $\langle 1 \rangle$ . The "IP3 Increase" bit is a programmable bit as shown in the Serial Programmable Interface section under the  $R_X$  Counter Latch Register. The IP3 =  $\langle 1 \rangle$  option will increase the supply current demand by 1.3 mA.

**Figure 13. First Mixer Input and Output Impedance Schematic**

**Figure 14. First Mixer Output Impedance**

Unit	Output Impedance
B IP3 = $\langle 0 \rangle$ (Set Low)	$304 \Omega // 3.7 \text{ pF}$
B IP3 = $\langle 1 \rangle$ (Set High)	$300 \Omega // 4.0 \text{ pF}$

Figures 13, 14, and 16 represent the input and output impedance for the first mixer. Notice that the input single-ended and differential impedances are basically the same. The output impedance as described in Figure 14 will be used to match to a ceramic or crystal filter's input impedance. A typical ceramic filter input impedance is  $330 \Omega$  while crystal filter input impedance is usually  $1500 \Omega$ . Exact impedance matching to ceramic filters are not critical, however, more attention needs to be given to the filter characteristics of a crystal filter. Crystal filters are much narrower. It is important to accurately match to these filters to guaranty a reasonable response.

To find the IF bandwidth response of the first mixer refer to Figure 22. The  $-3.0$  dB bandwidth point is approximately 13 MHz. Figure 15 is a summary of the first mixer feedthrough parameters.

**Figure 15. First Mixer Feedthrough Parameters**

Parameter	(dBm)
1st LO Feedthrough @ Mix <sub>1</sub> In <sub>1</sub>	$-70.0$
1st LO Feedthrough @ Mix <sub>1</sub> Out	$-55.5$
RF Feedthrough @ Mix <sub>1</sub> Out with $-30$ dBm	$-61.0$

**Figure 16. First Mixer Input Impedance over Input Frequency**

Unit	US Center Channels		France Center Channels	
	49 MHz	46 MHz	41 MHz	26 MHz
Single-Ended	$1550 \Omega // 3.7 \text{ pF}$	$1560 \Omega // 3.7 \text{ pF}$	$1570 \Omega // 3.8 \text{ pF}$	$1650 \Omega // 3.7 \text{ pF}$
Differential	$1600 \Omega // 1.8 \text{ pF}$	$1610 \Omega // 1.8 \text{ pF}$	$1670 \Omega // 1.8 \text{ pF}$	$1710 \Omega // 1.8 \text{ pF}$

NOTE: 11. Single-Ended data is from measured results. Differential data is from simulated results.

Figure 22. First IF Bandwidth

# MC13110A MC13111A

## Second Mixer

Figures 26 through 29 represents the second mixer transfer characteristics for the voltage conversion gain, output level, and intermodulation. There is a slight improvement in gain when the “IP3 bit” is set to <1> for the second mixer. (Note: This is the same programmable bit discussed earlier in the section.)

**Figure 23. Second Mixer Input and Output Impedance Schematic**

**Figure 24. Second Mixer Input and Output Impedances**

Unit	Input Impedance $R_{P1} // C_{P1}$	Output Impedance $R_{P0} // C_{P0}$
IP3 = <0> (Set Low)	2817 $\Omega$ // 3.6 pF	1493 $\Omega$ // 6.1 pF
IP3 = <1> (Set High)	2817 $\Omega$ // 3.6 pF	1435 $\Omega$ // 6.2 pF

The 2nd mixer input impedance is typically 2.8 k $\Omega$ . It requires an external 360  $\Omega$  parallel resistor for use with a standard 330  $\Omega$ , 10.7 MHz ceramic filter. The second mixer output impedance is 1.5 k $\Omega$  making it suitable to match standard 455 kHz ceramic filters.

The IF bandwidth response of the second mixer is shown in Figure 31. The -3.0 dB corner is 2.5 MHz. The feedthrough parameters are summarized in Figure 25.

**Figure 25. Second Mixer Feedthrough Parameters**

Parameter	(dBm)
2nd LO Feedthrough @ Mix <sub>2</sub> Out	-42.9
IF Feedthrough @ Mix <sub>2</sub> Out with -30 dBm	-61.7

**First Local Oscillator**

The 1st LO is a multi-vibrator oscillator. The tank circuit is composed of a parallel external capacitance and inductance, internal programmable capacitor matrix, and internal varactor. The local oscillator requires a voltage controlled input to the internal varactor and an external loop filter driven by on-board phase-lock control loop (PLL). The 1st LO internal component values have a tolerance of ±15%. A typical dc bias level on the LO Input and LO Output is 0.45 Vdc. The temperature coefficient of the varactor is +0.08%/°C. The curve in Figure 33 is the varactor control voltage range as it relates to varactor capacitance. It represents the expected internal capacitance for a given control voltage ( $V_{capCtrl}$ ) of the MC13110A and MC13111A. Figure 32 shows a representative schematic of the first LO function.

**Figure 32. First Local Oscillator Schematic**

To select the proper  $L_{ext}$  and  $C_{ext}$  we can do the following analysis. From Figure 34 it is observed that an inductor will have a significant affect on first LO performance, especially over frequency. The overall minimum Q required for first LO to function as it relates to the LO frequency is also given in Figure 34.

Choose an inductor value, say 470 nH. From Figure 34, the minimum operating Q is approximately 25. From the following equation:

$$Q_{Coil} = R_p / X_{Coil}$$

where:  $R_p$  = parallel equivalent impedance (Figure 35).

$C_{ext}$  can be determined as follows:

$$f_{LO} = \frac{1}{2\pi\sqrt{L_{ext}C_{ext}}}$$

where:  $L_{ext}$  = external inductance,  $C_{ext}$  = external capacitance.

Figure 34 clearly indicates that for lower coil values, higher quality factors (Q) are required for the first LO to function properly. Also, lower LO frequencies need higher Q's. In Figure 35 the internal programmable capacitor selection relative to the first LO frequency and the parallel impedance is shown. This information will help the user to decide what inductor ( $L_{ext}$ ) to choose for best performance in terms of Q.

Refer to the Auxiliary Register in the Serial Interface Section for further discussion on LO programmability.

# MC13110A MC13111A

## Second Local Oscillator

The 2nd LO is a CMOS oscillator. It is used as the PLL reference oscillator and local oscillator for the second frequency conversion in the RF receiver. It is designed to utilize an external parallel resonant crystal. See schematic in Figure 39.

Figure 39. Second Local Oscillator Schematic

Figure 40. Second Local Oscillator Input and Output Impedance

Input Impedance ( $R_{PI} // C_{PI}$ )	11.6 k $\Omega$ // 2.9 pF
Output Impedance ( $R_{PO} // C_{PO}$ )	9.6 k $\Omega$ // 2.7 pF

Figure 41 shows a typical gain/phase response of the second local oscillator. Load capacitance ( $C_L$ ), equivalent series resistance (ESR), and even supply voltage will have an effect on the 2nd LO response as shown in Figures 45 and 46. Except for the standby mode open loop gain is fairly constant as supply voltage increases from 2.5 V. This is due to the regulated voltage of 2.5 V on PLL  $V_{ref}$ . From the graphs it can be seen that optimum performance is achieved when  $C1$  equals  $C2$  ( $C1/C2 = 1$ ).

Figure 46 represents the ESR versus crystal load capacitance for the 2nd LO. This relationship was defined by using a 6.0 dB minimum loop gain margin at 3.6 V. This is considered the minimum gain margin to guarantee oscillator start-up.

Oscillator start-up is also significantly affected by the crystal load capacitance selection. In Figures 42 and 43 the relationship between crystal load capacitance, supply voltage, and external load capacitance ratio ( $C2/C1$ ), can be seen. The lower the load capacitance the better the performance.

Given the desired crystal load capacitance,  $C1$  and  $C2$  can be determined from Figure 47. It is also interesting to point out that current consumption increases when  $C1 \neq C2$ , as shown in Figure 44.

Be careful not to overdrive the crystal. This could cause a noise problem. An external series resistor on the crystal output can be added to reduce the drive level, if necessary.

**IF Limiter and Demodulator**

The limiting IF amplifier typically has about 110 dB of gain; the frequency response starts rolling off at 1.0 MHz. Decoupling capacitors should be placed close to Pins 31 and 32 to ensure low noise and stable operation. The IF input impedance is 1.5 kΩ. This is a suitable match to 455 kHz ceramic filters.

**Figure 48. IF Limiter Schematic**

**Figure 49. Limiter Input Impedance**

Unit	Input Impedance (R <sub>PI</sub> )	Input Impedance (C <sub>PI</sub> )
Lim In	1538 Ω	15.7 pF

**Figure 50. Quadrature Detector Demodulator Schematic**

The quadrature detector is coupled to the IF with an external capacitor between Pins 27 and 28. Thus, the recovered signal level output is increased for a given bandwidth by increasing the capacitor. The external quadrature component may be either a LCR resonant circuit, which may be adjustable, or a ceramic resonator which is usually fixed tuned. (More on ceramic resonators later.)

The bandwidth performance of the detector is controlled by the loaded Q of the LC tank circuit (Figure 50). The following equation defines the components which set the detector circuit's bandwidth:

$$(1) R_T = Q X_L,$$

where  $R_T$  is the equivalent shunt resistance across the LC tank.  $X_L$  is the reactance of the quadrature inductor at the IF frequency ( $X_L = 2\pi f L$ ).

The 455 kHz IF center frequency is calculated by:

$$(2) f_c = [2\pi (L C_p)^{1/2}]^{-1}$$

where L is the parallel tank inductor.  $C_p$  is the equivalent parallel capacitance of the parallel resonant tank circuit.

The following is a design example for a detector at 455 kHz and a specific loaded Q:

The loaded Q of the quadrature detector is chosen somewhat less than the Q of the IF bandpass for margin. For an IF frequency of 455 kHz and an IF bandpass of 20 kHz,

the IF bandpass Q is approximately 23; the loaded Q of the quadrature tank is chosen slightly lower at 15.

**Example:**

Let the total external C = 180 pF. (Note: the capacitance is the typical capacitance for the quad coil.) Since the external capacitance is much greater than the internal device and PCB parasitic capacitance, the parasitic capacitance may be neglected.

Rewrite equation (2) and solve for L:

$$L = (0.159)^2 / (C f_c^2)$$

$L = 678 \mu\text{H}$ ; Thus, a standard value is chosen:

$L = 680 \mu\text{H}$  (surface mount inductor)

The value of the total damping resistor to obtain the required loaded Q of 15 can be calculated from equation (1):

$$R_T = Q(2\pi f L)$$

$$R_T = 15(2\pi)(0.455)(680) = 29.5 \text{ k}\Omega$$

The internal resistance,  $R_{int}$  at the quadrature tank Pin 27 is approximately 100 kΩ and is considered in determining the external resistance,  $R_{ext}$  which is calculated from:

$$R_{ext} = ((R_T)(R_{int})) / (R_{int} - R_T)$$

$R_{ext} = 41.8 \text{ k}\Omega$ ; Thus, choose a standard value:

$R_{ext} = 39 \text{ k}\Omega$

In Figure 50, the  $R_{ext}$  is chosen to be 22.1 kΩ. An adjustable quadrature coil is selected. This tank circuit represents one popular network used to match to the 455 kHz carrier frequency. The output of the detector is represented as a "S-curve" as shown in Figure 52. The goal is to tune the inductor in the area that is most linear on the "S-curve" (minimum distortion) to optimize the performance in terms of dc output level. The slope of the curve can also be adjusted by choosing higher or lower values of  $R_{ext}$ . This will have an affect on the audio output level and bandwidth. As  $R_{ext}$  is increased the detector output slope will decrease. The maximum audio output swing and distortion will be reduced and the bandwidth increased. Of course, just the opposite is true for smaller  $R_{ext}$ .

A ceramic discriminator is recommended for the quadrature circuit in applications where fixed tuning is desired. The ceramic discriminator and a 5.6 kΩ resistor are placed from Pin 27 to  $V_{CC}$ . A 22 pF capacitor is placed from Pin 28 to 27 to properly drive the discriminator. MuRata Erie has designed a resonator for this part (CDBM455C48 for USA & A/P regions and CDBM450C48 for Europe). This resonator has been designed specifically for the MC13110/111 family. Figure 51 shows the schematic used to generate the "S-curve" and waveform shown in Figure 54 and 55.

# MC13110A MC13111A

**Figure 51. Ceramic Resonator Demodulator Schematic with Murata CDBM450C48**

(CDBM455C48 US; CDBM450C48 France)

The “S-curve” for the ceramic discriminator shown in Figure 54 is centered around 450 kHz. It is for the French application. The same resonator is also used for the US application and is centered around 455 kHz. Clearly, the “S-curves” for the resonator and quad coil have very similar limiter outputs. As discussed previously, the slope of the “S-curve” centered around the center frequency can be controlled by the parallel resistor,  $R_{ext}$ . Distortion, bandwidth, and audio output level will be affected.

## IF LIMITER AND DEMODULATION

**Figure 52. S-Curve of Limiter Discriminator with Quadrature Coil**

**Figure 53. Typical Limiter Output Waveform with Quadrature Coil**

**Figure 54. S-Curve of Limiter Discriminator with Ceramic Resonator**

**Figure 55. Typical Limiter Output Waveform with Ceramic Resonator**

**RSSI and Carrier Detect**

The Received Signal Strength Indicator (RSSI) indicates the strength of the IF level. The output is proportional to the logarithm of the IF input signal magnitude. RSSI dynamic range is typically 80 dB. A 187 kΩ resistor to ground is provided internally to the IC. This internal resistor converts the RSSI current to a voltage level at the “RSSI” pin. To improve the RSSI accuracy over temperature an internal compensated reference is used. Figure 56 shows the RSSI versus RF input. The slope of the curve is 16.5 mV/dB.

The Carrier Detect Output (CD Out) is an open-collector transistor output. An external pull-up resistor of 100 kΩ will be required to bias this device. To form a carrier detect filter a capacitor needs to be connected from the RSSI pin to ground. The carrier detect threshold is programmable through the MPU interface (see “Carrier Detect Threshold Programming” in the serial interface section). The range can be scaled by connecting additional external resistance from

the RSSI pin to ground in parallel with the capacitor. From Figure 57, the affect of an external resistor at RSSI on the carrier detect level can be noticed. Since there is hysteresis in the carrier detect comparator, one trip level can be found when the input signal is increased while the another one can be found when the signal is decreased.

Figure 58 represents the RSSI ripple in relation to the RF input for different filtering capacitors at RSSI. Clearly, the higher the capacitor, the less the ripple. However, at low carrier detect thresholds, the ripple might supersede the hysteresis of the carrier detect. The carrier detect output may appear to be unstable. Using a large capacitor will help to stabilize the RSSI level, but RSSI charge time will be affected. Figure 59 shows this relationship.

The user must decide on a compromise between the RSSI ripple and RSSI start-up time. Choose a 0.01 μf capacitor as a starting point. For low carrier detect threshold settings, a 0.047 μf capacitor is recommended.

## MC13110A MC13111A

### RF System Performance

The sensitivity of the IC is typically 0.4  $\mu$ Vrms matched (single ended or differential) with no preamp. To achieve suitable system performance, a preamp and passive duplexer may be used. In production final test, each section of the IC is separately tested to guarantee its system performance in the specific application. The preamp and duplexer (differential, matched input) yields typically  $-115$  dBm @ 12 dB SINAD sensitivity performance under full duplex operation. See Figure 45 and 48.

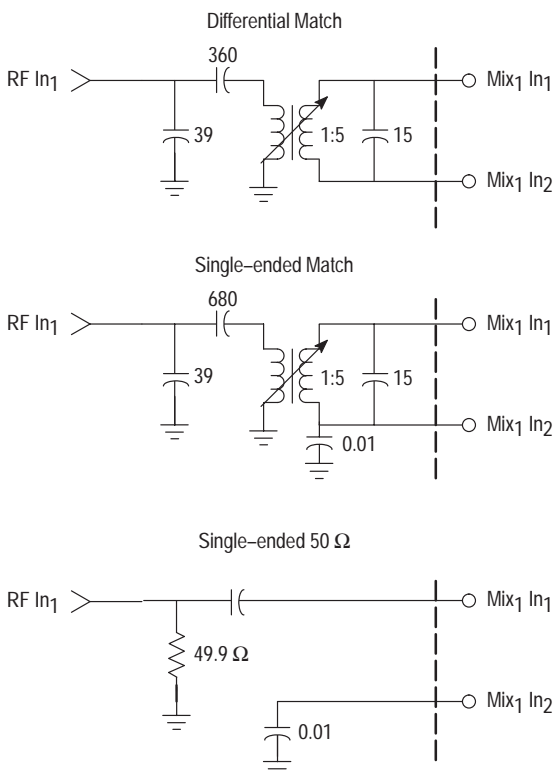

The duplexer is important to achieve full duplex operation without significant “de-sensing” of the receiver by the transmitter. The combination of the duplexer and preamp circuit should attenuate the transmitter power to the receiver by over 60 dB. This will improve the receiver system noise figure without giving up too much IMD performance.

The duplexer may be a two piece unit offered by Shimida, Sansui, or Toko products (designed for 25 channel CT-0 cordless phone). The duplexer frequency response at the receiver port has a notch at the transmitter frequency band of about 35 to 40 dB with a 2.0 to 3.0 dB insertion loss at the receiver frequency band.

The preamp circuit utilizes a tuned transformer at the output side of the amplifier. This transformer is designed to bandpass filter at the receiver input frequency while rejecting the transmitter frequency. The tuned preamp also improves the noise performance by reducing the bandwidth of the pass band and by reducing the second stage contribution of the 1st mixer. The preamp is biased such that it yields suitable noise figure and gain.

The following matching networks have been used to obtain 12 dB SINAD sensitivity numbers:

**Figure 60. Matching Input Networks**

The exact impedance looking into the RF In<sub>1</sub> pin is displayed in the following table along with the sensitivity levels.

**Figure 61. 12 dB SINAD Sensitivity Levels, US Handset Application Channel 21**

	Sensitivity (dBm)	Input Impedance (dBm)
Differential matched	-115.3	50.2 $\pm$ 0.1j
Single-ended match	-114.8	50.2 $\pm$ 0.1j
Single-ended 50 $\Omega$	-100.1	50.2 $\pm$ 0.1j

The graphs in Figures 64 to 69 are performance results based on Evaluation Board Schematic (Figure 137). This evaluation board did not use a duplexer or preamp stage. Figure 62 is a summary of the RF performance and Figure 63 contains the French RF Performance Summary.

### Receive Audio Path

The  $R_X$  Audio signal path begins at “Rx Audio In” and goes through the IC to “E Out”. The “ $R_X$  Audio In”, “Scr Out”, and “E In” pins are all ac-coupled. This signal path consists of filters; programmable  $R_X$  gain adjust,  $R_X$  mute, and volume control, and finally the expander. The typical maximum output voltage at “E Out” should be approximately 0 dBV @ THD = 5.0% .

Figures 71 to 73 represent the receive audio path filter response. The filter response attenuation is very sharp above 3900 Hz, which is the cutoff frequency. Inband (audio), out-of-band, and ripple characteristics are also shown in these graphs.

The group delay (Figure 75) has a peak around 6.5 kHz. This spike is formed by rapid change in the phase at the frequency. In practice this does not cause a problem since the signal is attenuated by at least 50 dB.

The output capability at “Scr Out” and “E Out” are shown in Figures 76, 77, and 78. The results were obtained by increasing the input level for 2.0% distortion at the outputs.

In Figure 70, noise data for the  $R_X$  audio path is shown. At Scr Out, the noise level clearly rises when the scrambler is

enabled. However, assuming a nominal output level of -20 dBV (100 mVrms) at the 0 dB gain setting, the noise floor is more than 56 dB below the audio signal. However, the noise data at E Out and SA Out is much more improved.

### Speaker Amp

The Speaker Amp is an inverting rail-to-rail operational amplifier. The noninverting input is connected to the internal VB reference. External resistors and capacitors are used to set the gain and frequency response. The “SA In” input pin must be ac-coupled. The typical output voltage at “SA Out” is 2.6 V<sub>pp</sub> with a 130  $\Omega$  load. The speaker amp response is shown in Figures 79 and 80.

### Data Amp Comparator

The data amp comparator is an inverting hysteresis comparator. Its open collector output has an internal 100 k $\Omega$  pull-up resistor. A band pass filter is connected between the “Det Out” pin and the “DA In” pin with component values as shown in the Application Circuit schematic. The “DA In” input signal needs to be ac-coupled, too.

## MC13110A MC13111A

### Transmit Audio Path

This portion of the audio path goes from “C In” to “T<sub>X</sub> Out”. The “C In” pin will be ac-coupled. The audio transmit signal path includes automatic level control (ALC) (also referred to as the Compressor), T<sub>X</sub> mute, limiter, filters, and T<sub>X</sub> gain adjust. The ALC provides “soft” limiting to the output signal swing as the input voltage slowly increases. With this technique the gain is slightly lowered to help reduce distortion of the audio signal. The limiter section provides hard limiting due to rapidly changing signal levels, or transients. This is accomplished by clipping the signal peaks. The ALC, T<sub>X</sub> mute, and limiter functions can be enabled or disabled via the MPU serial interface. The T<sub>X</sub> gain adjust can also be remotely controlled to set different desired signal levels. The typical maximum output voltage at “T<sub>X</sub> Out” should be approximately 0 dBV @ THD = 5.0%.

Figures 82 to 86 represent the transmit audio path filter response. The filter response attenuation, again, is very definite above 3800 Hz. This is the filter cutoff frequency. Inband (audio), wideband, and ripple characteristics are also shown in these graphs.

The compressor transfer characteristics, shown in Figure 87, has three different slopes. A typical compressor slope can be found between -55 and -15 dBV. Here the slope is 2.0. At an input level above -15 dBV the automatic level control (ALC) function is activated and prevents hard clipping of the output. The slope below -55 dBV input level is one. This is where the compressor curve ends. Above 5.0 dBV the output actually begins to decrease and distort. This is due to supply voltage limitations.

In Figure 88 the ALC function is off. Here the compressor curve continues to increase above -15 dBV up to -4.0 dBV.

The limiter begins to clip the output signal at this level and distortion is rapidly rising. Similarly, Figure 68 (ALC and Limiter Off) shows to compressor transfer curve extending all the way up to the maximum output. Finally, Figure 90 through 93 show the T<sub>X</sub> Out signal versus several combinations of ALC and Limiter selected.

Figure 81 is the noise data measured for the MC13110A/13111A. This data is for 0 dB gain setting and -20 dBV (100 mVrms) audio levels.

### Mic Amp

Like the Speaker Amp the Mic Amp is also an inverting rail-to-rail operational amplifier. The noninverting input terminal is connected to the internal VB reference. External resistors and capacitors are used to set the gain and frequency response. The “T<sub>X</sub> In” input is ac-coupled.

## PLL SYNTHESIZER SECTION

### PLL Frequency Synthesizer General Description

Figure 95 shows a simplified block diagram of the programmable universal dual phase locked loop (PLL) designed into the MC13110A and MC13111A IC. This dual PLL is fully programmable through the MCU serial interface and supports most country channel frequencies including USA (25 ch), Spain, Australia, Korea, New Zealand, U.K., Netherlands, France, and China (see channel frequency tables in AN1575, "Worldwide Cordless Telephone Frequencies").

The 2nd local oscillator and reference divider provide the reference frequency signal for the  $R_X$  and  $T_X$  PLL loops. The programmed divider value for the reference divider is selected based on the crystal frequency and the desired  $R_X$  and  $T_X$  reference frequency values. For the U.K., additional divide by 25 and divide by 4 blocks are provided to allow for generation of the 1.0 kHz and 6.2 kHz reference frequencies.

The 14-bit  $R_X$  counter is programmed for the desired first local oscillator frequency. The 14-bit  $T_X$  counter is programmed for the desired transmit channel frequency. All counters power-up to a set default state for USA channel #21 using a 10.24 MHz reference frequency crystal (see power-up default latch register state in the Serial Programmable Interface section).

To extend the sensitivity of the 1st LO for U.S. 25 channel operation, internal fixed capacitors can be connected to the tank circuit through microprocessor programmable control. When designing the external PLL loop filters, it is recommended that the  $T_X$  and  $R_X$  phase detectors be considered as current drive type outputs. The loop filter control voltage must be 0.5 V away from either the positive or negative supply rail.

### PLL I/O Pin Configurations

The 2nd LO,  $R_X$  and  $T_X$  PLL's, and MPU serial interface are powered by the internal voltage regulator at the "PLL  $V_{ref}$ " pin. The "PLL  $V_{ref}$ " pin is the output of a voltage regulator which is powered from the "VCC Audio" power supply pin. It is regulated by an internal bandgap voltage reference. Therefore, the maximum input and output levels for most of the PLL I/O pins ( $LO_2$  In,  $LO_2$  Out,  $R_X$  PD,  $T_X$  PD,  $T_X$  VCO) is the regulated voltage at the "PLL  $V_{ref}$ " pin. The ESD protection diodes on these pins are also connected to "PLL  $V_{ref}$ ".

Internal level shift buffers are provided for the pins (Data, Clk, EN, Clk Out) which connect directly to the

microprocessor. The maximum input and output levels for these pins is  $V_{CC}$ . Figure 94 shows a simplified schematic of the I/O pins.

**Figure 94. PLL I/O Pin Simplified Schematics**

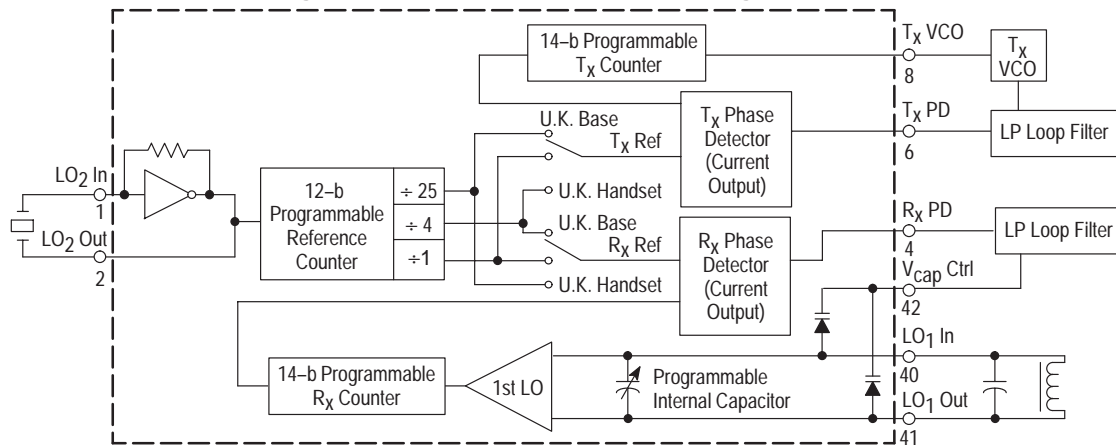

### PLL Loop Control Voltage Range

The control voltage for the  $T_X$  and  $R_X$  loop filters is set by the phase detector outputs which drive the external loop filters. The phase detectors are best considered to have a current mode type output. The output can have three states; ground, high impedance, and positive supply, which in this case is the voltage at "PLL  $V_{ref}$ ". When the loop is locked the phase detector outputs are at high impedance. An exception of this state is for narrow current pulses, referenced to either the positive or negative supply rails. If the loop voltages get within 0.5 V of either rail the linear current output starts to degrade. The phase detector current source was not designed to operate at the supply rails. VCO tuning range will also be limited by this voltage range.

The maximum loop control voltage is the "PLL  $V_{ref}$ " voltage which is 2.5 V. If a higher loop control voltage range is desired, the "PLL  $V_{ref}$ " pin can be pulled to a higher voltage. It can be tied directly to the  $V_{CC}$  voltage (with suitable filter capacitors connected close to each pin). When this is done, the internal voltage regulator is automatically disabled. This is commonly used in the telephone base set where an external 5.0 V regulated voltage is available. It is important to remember, that if "PLL  $V_{ref}$ " is tied to  $V_{CC}$  and  $V_{CC}$  is not a regulated voltage, the PLL loop parameters and lock-up time will vary with supply voltage variation. The phase detector gain constant,  $K_{pd}$ , will not be affected if the "PLL  $V_{ref}$ " is tied to  $V_{CC}$ .

**Figure 95. Dual PLL Simplified Block Diagram**

**Loop Filter Characteristics**

Lets consider the following discussion on loop filters. The fundamental loop characteristics, such as capture range, loop bandwidth, lock-up time, and transient response are controlled externally by loop filtering.

Figure 96 is the general model for a Phase Lock Loop (PLL).

Where:

- $K_{pd}$  = Phase Detector Gain Constant
- $K_f$  = Loop Filter Transfer Function
- $K_o$  = VCO Gain Constant
- $K_n$  = Divide Ratio (1/N)
- $f_i$  = Input frequency
- $f_o$  = Output frequency
- $f_o/N$  = Feedback frequency divided by N

From control theory the loop transfer function can be represented as follows:

$$A = K_{pd} K_f K_o K_n \text{ Open loop gain}$$

$K_{pd}$  can be either expressed as being 2.5 V/4.0  $\pi$  or 1.0 mA/2.0  $\pi$  for the CT-0 circuits. More details about performance of different type PLL loops, refer to Motorola application note AN535.

The loop filter can take the form of a simple low pass filter. A current output, type 2 filter will be used in this discussion since it has the advantage of improved step response, velocity, and acceleration.

The type 2 low pass filter discussed here is represented as follows:

**Figure 97. Loop Filter with Additional Integrating Element**

From Figure 97, capacitor C1 forms an additional integrator, providing the type 2 response, and filters the discrete current steps from the phase detector output. The function of the additional components R2 and C2 is to create a pole and a zero (together with C1) around the 0 dB point of the open loop gain. This will create sufficient phase margin for stable loop operation.

In Figure 98, the open loop gain and the phase is displayed in the form of a Bode plot. Since there are two integrating functions in the loop, originating from the loopfilter and the VCO gain, the open loop gain response follows a

second order slope (-40 dB/dec) creating a phase of -180 degrees at the lower and higher frequencies. The filter characteristic needs to be determined such that it is adding a pole and a zero around the 0 dB point to guarantee sufficient phase margin in this design ( $Q_p$  in Figure 98).

**Figure 98. Bode Plot of Gain and Phase in Open Loop Condition**

The open loop gain including the filter response can be expressed as:

$$A_{openloop} = \frac{K_{pd}K_o(1 + jw(R2C2))}{jwK_n \left( jw \left( 1 + jw \left( \frac{R2C1C2}{C1 + C2} \right) \right) \right)} \quad (1)$$

The two time constants creating the pole and the zero in the Bode plot can now be defined as:

$$T1 = \frac{R2C1C2}{C1 + C2} \quad T2 = R2C2 \quad (2)$$

By substituting equation (2) into (1), it follows:

$$A_{openloop} = \left( \frac{K_{pd}K_oT1}{w^2C1K_nT2} \right) \left( \frac{1 + jwT2}{1 + jwT1} \right) \quad (3)$$

The phase margin (phase + 180) is thus determined by:

$$Q_p = \arctan(wT2) - \arctan(wT1) \quad (4)$$

At  $w=w_p$ , the derivative of the phase margin may be set to zero in order to assure maximum phase margin occurs at  $w_p$  (see also Figure 98). This provides an expression for  $w_p$ :

$$\frac{dQ_p}{dw} = 0 = \frac{T2}{1 + (wT2)^2} - \frac{T1}{1 + (wT1)^2} \quad (5)$$

$$w = w_p = \frac{1}{\sqrt{T2T1}} \quad (6)$$

Or rewritten:

$$T1 = \frac{1}{w_p^2 T2} \quad (7)$$

By substituting into equation (4), solve for T2:

$$T2 = \frac{\tan\left(\frac{Q_p}{2} + \frac{\pi}{4}\right)}{w_p} \quad (8)$$

By choosing a value for  $w_p$  and  $Q_p$ , T1 and T2 can be calculated. The choice of  $Q_p$  determines the stability of the loop. In general, choosing a phase margin of 45 degrees is a good choice to start calculations. Choosing lower phase margins will provide somewhat faster lock-times, but also generate higher overshoots on the control line to the VCO. This will present a less stable system. Larger values of phase margin provide a more stable system, but also increase lock-times. The practical range for phase margin is 30 degrees up to 70 degrees.

The selection of  $w_p$  is strongly related to the desired lock-time. Since it is quite complicated to accurately calculate lock time, a good first order approach is:

$$T_{lock} \approx \frac{3}{w_p} \quad (9)$$

Equation (9) only provides an order of magnitude for lock time. It does not clearly define what the exact frequency difference is from the desired frequency and it does not show the effect of phase margin. It assumes, however, that the phase detector steps up to the desired control voltage without hesitation. In practice, such step response approach is not really valid. The two input frequencies are not locked. Their phase maybe momentarily zero and force the phase detector into a high impedance mode. Hence, the lock times may be found to be somewhat higher.

In general,  $w_p$  should be chosen far below the reference frequency in order for the filter to provide sufficient attenuation at that frequency. In some applications, the reference frequency might represent the spacing between channels. Any feedthrough to the VCO that shows up as a spur might affect adjacent channel rejection. In theory, with the loop in lock, there is no signal coming from the phase detector. But in practice leakage currents will be supplied to both the VCO and the phase detector. The external capacitors may show some leakage, too. Hence, the lower  $w_p$ , the better the reference frequency is filtered, but the longer it takes for the loop to lock.

As shown in Figure 98, the open loop gain at  $w_p$  is 1 (or 0 dB), and thus the absolute value of the complex open loop gain as shown in equation (3) solves C1:

$$C1 = \left(\frac{K_{pd}K_oT1}{w^2K_nT2}\right) \sqrt{\frac{(1 + w_pT2)^2}{(1 + w_pT1)^2}} \quad (10)$$

With C1 known, and equation (2) solve C2 and R2:

$$C2 = C1\left(\frac{T2}{T1} - 1\right) \quad (11)$$

$$R2 = \frac{T2}{C2} \quad (12)$$

The VCO gain is dependent on the selection of the external inductor and the frequency required. The free running frequency of the VCO is determined by:

$$f = \frac{1}{2\pi\sqrt{LC_T}} \quad (13)$$

In which L represents the external inductor value and  $C_T$  represents the total capacitance (including internal capacitance) in parallel with the inductor. The VCO gain can be easily calculated via the internal varicap transfer curve shown below.

Figure 99. Varicap Capacitance versus Control Voltage

As can be derived from Figure 99, the varicap capacitance changes 1.3 pF over the voltage range from 1.0 V to 2.0 V:

$$\Delta Cvar = \frac{1.3 \text{ pF}}{V} \quad (14)$$

Combining (13) with (14) the VCO gain can be determined by:

$$K_o = \frac{1}{jw} \left\{ \frac{1}{2\pi\sqrt{L\left(C_T + \frac{\Delta Cvar}{2}\right)}} - \frac{1}{2\pi\sqrt{L\left(C_T + \frac{\Delta Cvar}{2}\right)}} \right\} \quad (15)$$

Although the basic loopfilter previously described provides adequate performance for most applications, an extra pole may be added for additional reference frequency filtering. Given that the channel spacing in a CT-0 telephone set is based on the reference frequency, and any feedthrough to

the first LO may effect parameters like adjacent channel rejection and intermodulation. Figure 100 shows a loopfilter architecture incorporating an additional pole.

**Figure 100. Loop Filter with Additional Integrating Element**

For the additional pole formed by R3 and C3 to be efficient, the cut-off frequency must be much lower than the reference frequency. However, it must also be higher than  $\omega_p$  in order not to compromise phase margin too much. The following equations were derived in a similar manner as for the basic filter previously described.

Similarly, it can be shown:

$$A_{\text{openloop}} = -\frac{K_{pd}K_o}{K_n\omega^2((C1 + C2 + C3) - \omega^2C1C2C3R2R3)} + \frac{1 + j\omega T2}{1 + j\omega T1} \quad (16)$$

In which:

$$T1 = \frac{(C1 + C2)T2 + (C1C2)T3}{C1 + C2 + C3 - \omega^2C1T2T3} \quad (17)$$

$$T2 = R2C2 \quad (18) \quad T3 = R3C3 \quad (19)$$

From T1 it can be derived that:

$$C2 = \frac{(T1 + T2)C3 - C1(T2 + T3 - T1 + \omega^2T1T2T3)}{T3 - T1} \quad (20)$$

In analogy with (10), by forcing the loopgain to 1 (0 dB) at  $\omega_p$ , we obtain:

$$C1(T1 + T2) + C2T3 + C3T2 = \left(\frac{K_{pd}K_o}{K_n\omega_p^2}\right) \sqrt{\frac{1 + (\omega_p T2)^2}{1 + (\omega_p T1)^2}} \quad (21)$$

Solving for C1:

$$C1 = \frac{(T2 - T1)T3C3 - (T3 - T1)T2C3 + (T3 - T1)\left(\frac{K_{pd}K_o T1}{\omega_p^2 K_n}\right) \sqrt{\frac{1 + (\omega_p T2)^2}{1 + (\omega_p T1)^2}}}{(T3 - T1)T2 + (T3 - T1)T3 - (T2 + T3 - T1 + \omega_p^2 T1 T2 T3)T3} \quad (22)$$

By selecting  $\omega_p$  via (9), the additional time constant expressed as T3, can be set to:

$$T3 = \frac{1}{K\omega_p} \quad (23)$$

## MC13110A MC13111A

The K-factor shown determines how far the additional pole frequency will be separated from  $\omega_p$ . Selecting too small of a K-factor, the equations may provide negative capacitance or resistor values. Too large of a K-factor may not provide the maximum attenuation.

By selecting R3 to be 100 k $\Omega$ , C3 becomes known and C1 and C2 can be solved from the equations. By using equations (8) and (7), time constants T2 and T1 can be derived by selecting a phase margin. Finally, R2 follows from T2 and C2.

The following pages, the loopfilter components are determined for both handset and basaset the US application based on the equations described. Choose K to be approximately five times  $\omega_p$  ( $5\omega_p$ ).

In an application,  $\omega_p$  is chosen to be 20 times less than the reference frequency of 5.0 kHz and the phase margin has

been set to 45 degrees. This provides a lock time according to (9) of about 2.0 ms (order of magnitude). With the adjacent channels spaced at least 15 kHz away, reference feedthrough at  $\omega_p$  will not be directly disastrous but still, the additional pole may be added in the loopfilter design for added safety.

In an application,  $\omega_p$  is chosen to be 20 times less than the reference frequency of 5.0 kHz and the phase margin has been set to 45 degrees. This provides a lock time according to (9) of about 2.0 ms (order of magnitude). With the adjacent channels spaced at least 15 kHz away, reference feedthrough at  $\omega_p$  will not be directly disastrous but still, the additional pole may be added in the loopfilter design for added safety.

## SERIAL PROGRAMMABLE INTERFACE

### Microprocessor Serial Interface

The Data, Clock, and Enable (“Data”, “Clk”, and “EN” respectively) pins provide a MPU serial interface for programming the reference counters, the transmit and receive channel divide counters, the switched capacitor filter clock counter, and various other control functions. The “Data” and “Clk” pins are used to load data into the MC13111A shift register (Figure 109). Figure 105 shows the timing required on the “Data” and “Clk” pins. Data is clocked into the shift register on positive clock transitions.

**Figure 105. Data and Clock Timing Requirement**

After data is loaded into the shift register, the data is latched into the appropriate latch register using the “EN” pin. This is done in two steps. First, an 8-bit address is loaded into the shift register and latched into the 8-bit address latch register. Then, up to 16-bits of data is loaded into the shift register and latched into the data latch register. It is specified by the address that was previously loaded. Figure 106 shows the timing required on the EN pin. Latching occurs on the negative EN transition.

**Figure 106. Enable Timing Requirement**

The state of the “EN” pin when clocking data into the shift register determines whether the data is latched into the address register or a data register. Figure 107 shows the address and data programming diagrams. In the data programming mode, there must not be any clock transitions when “EN” is high. The clock can be in a high state (default high) or a low state (default low) but must not have any transitions during the “EN” high state. The convention in these figures is that latch bits to the left are loaded into the shift register first. A minimum of four “Clk” rising edge transition must occur before a negative “EN” transition will latch data or an address into a register.

**Figure 107. Microprocessor Interface Programming Mode Diagrams**

The MPU serial interface is fully operational within 100  $\mu$ s after the power supply has reached its minimum level during power-up (see Figure 108). The MPU Interface shift registers and data latches are operational in all four power saving modes; Inactive, Standby,  $R_X$ , and Active Modes. Data can be loaded into the shift registers and latched into the latch registers in any of the operating modes.

**Figure 108. Microprocessor Serial Interface Power-Up Delay**

# MC13110A MC13111A

## Data Registers

Figure 109 shows the data latch registers and addresses which are used to select each of each registers. Latch bits to the left (MSB) are loaded into the shift register first. The LSB bit must always be the last bit loaded into the shift register. Bits preceding the register must be “0’s” as shown.

### Power-Up Defaults for Data Registers

When the IC is first powered up, all latch registers are initialized to a defined state. The device is initially placed in the

R<sub>X</sub> mode with all mutes active. The reference counter is set to generate a 5.0 kHz reference frequency from a 10.24 MHz crystal. The switched capacitor filter clock counter is set properly for operation with a 10.24 MHz crystal. The T<sub>X</sub> and R<sub>X</sub> counter registers are set for USA handset channel frequency, number 21 (Channel 6 for previous FCC 10 Channel Band). Figure 110 shows the initial power-up states for all latch registers.

Figure 109. Microprocessor Interface Data Latch Registers

# MC13110A MC13111A

Figure 110. Latch Register Power-Up Defaults

Register	Count	MSB								LSB							
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SCF (MC13110A)	31	–	0	0	0	0	1	1	1	0	0	0	1	1	1	1	1
SCF (MC13111A)	31	–	0	0	0	0	1	1	1	–	–	0	1	1	1	1	1
Aux	N/A	–	–	–	–	–	–	–	–	–	0	0	0	0	0	0	0

NOTE: 12. Bits 6 and 7 in the SCF latch register are "Don't Cares" for the MC13111A since this part does not have a scrambler.

### T<sub>X</sub> and R<sub>X</sub> Counter Registers

The 14 bit T<sub>X</sub> and R<sub>X</sub> counter registers are used to select the transmit and receive channel frequencies. In the R<sub>X</sub> counter there is an "IP3 Increase" bit that allows the ability to trade off increased receiver mixer performance versus reduced power consumption. With "IP3 increase" = <1>, there is about a 10 dB improvement in 1 dB compression and 3rd order intercept for both the 1st and 2nd mixers. However, there is also an increase in power supply current of 1.3 mA. The power-up default for the MC13111A is "IP3 Increase" = <0>. The register bits are shown in Figure 111.

### Reference Counter Register

#### Reference Counter

Figure 113 shows how the reference frequencies for the R<sub>X</sub> and T<sub>X</sub> loops are generated. All countries except the U.K. require that the T<sub>X</sub> and R<sub>X</sub> reference frequencies be identical.

In this case, set "U.K. Base Select" and "U.K. Handset Select" bits to "0". Then the fixed divider is set to "1" and the T<sub>X</sub> and R<sub>X</sub> reference frequencies will be equal to the crystal oscillator frequency divided by the programmable reference counter value.

The U.K. is a special case which requires a different reference frequency value for T<sub>X</sub> and R<sub>X</sub>. For U.K. base operation, set "U.K. Base Select" to "1". For U.K. handset operation, set "U.K. Handset Select" to "1". The Netherlands is also a special case. A 2.5 kHz reference frequency is used for both the T<sub>X</sub> and R<sub>X</sub> reference and the total divider value required is 4096. This is larger than the maximum divide value available from the 12-bit reference divider (4095). In this case, set "U.K. Base Select" to "1" and set "U.K. Handset Select" to "1". This will give a fixed divide by 4 for both the T<sub>X</sub> and R<sub>X</sub> reference. Then set the reference divider to 1024 to get a total divider of 4096.

**Figure 115. Mode Control Register**

**Reference Frequency Selection**

The “LO<sub>2</sub> In” and “LO<sub>2</sub> Out” pins form a reference oscillator when connected to an external parallel-resonant crystal. The reference oscillator is also the second local oscillator for the RF Receiver. Figure 114 shows the relationship between different crystal frequencies and reference frequencies for cordless phone applications in various countries. “LO<sub>2</sub> In” may also serve as an input for an externally generated reference signal which is ac-coupled. The switched capacitor filter 6-bit programmable counter must be programmed for the crystal frequency that is selected since this clock is derived from the crystal frequency and must be held constant regardless of the crystal that is selected. The actual switched capacitor clock divider ratio is twice the programmed divider ratio due to the a fixed divide by 2.0 after the programmable counter. The scrambler mixer modulation frequency is the switched capacitor clock divided by 40 for the MC13110A.

**Mode Control Register**

The power saving modes; mutes, disables, volume control, and microprocessor clock output frequency are all

set by the Mode Control Register. Operation of the Control Register is explained in Figures 115 through 119.

**Figure 116. Mute and Disable Control Bit Descriptions**

Power Saving Operating Modes

When the MC13110A or MC13111A are used in a handset, it is important to conserve power in order to prolong battery life. There are five modes of operation for the MC13110A/MC13111A; Active, R<sub>X</sub>, Standby, Interrupt, and Inactive. They are Active, R<sub>X</sub>, and Standby. In the Active mode, all circuit blocks are powered. In the R<sub>X</sub> mode, all circuitry is powered down except for those circuit sections needed to receive a transmission from the base. In the Standby and Interrupt Modes, all circuitry is powered down except for the circuitry needed to provide the clock output for the microprocessor. In the Inactive Mode, all circuitry is powered down except the MPU serial interface. Latch memory is maintained in all modes. Figure 117 shows the control register bit values for selection of each power saving mode and Figure 118 shows the circuit blocks which are powered in each of these operating modes.

Figure 117. Power Saving Mode Selection

NOTE: 15. In Standby and Inactive Modes, “PLL V<sub>ref</sub>” remains powered but is not regulated. It will fluctuate with V<sub>CC</sub>.

Power Saving Application

In some handset applications it may be desirable to power down all circuitry including the microprocessor (MPU). First put the MC13110A/MC13111A into the Inactive mode. This turns off the MPU Clock Output (see Figure 119) and disables the microprocessor. Once a command is given to switch the IC into an “Inactive” mode, the MPU Clock output will remain active for a minimum of one reference counter cycle (about 200 μs) and up to a maximum of two reference counter cycles (about 400 μs). This is performed in order to give the MPU adequate time to power down.

An external timing circuit should be used to initiate the turn-on sequence. The “CD Out” pin has a dual function. In the Active and R<sub>X</sub> modes it performs the carrier detect function. In the Standby and Inactive modes the carrier detect circuit is disabled and the “CD Out” pin is in a “High” state, because of an external pull-up resistor. In the Inactive mode, the “CD Out” pin is the input for the hardware interrupt function. When the “CD Out” pin is pulled “low”, by the external timing circuit, the IC switches from the Inactive to the Interrupt mode. Thereby turning on the MPU Clock Output. The MPU can then resume control of the IC. The “CD Out” pin must remain low until the MPU changes the operating mode from Interrupt to Standby, Active, or R<sub>X</sub> modes.

# MC13110A MC13111A

Figure 119. Power Saving Application

### MPU "Clk Out" Divider Programming

The "Clk Out" signal is derived from the second local oscillator. It can be used to drive a microprocessor (MPU) clock input. This will eliminate the need for a separate crystal to drive the MPU, thus reducing system cost. Figure 120 shows the relationship between the second LO crystal frequency and the

clock output for each divide value. Figure 121 shows the "Clk Out" register bit values. With a 10.24 MHz crystal, the divide by 312.5 gives the same clock frequency as a clock crystal and allows the MPU to display the time on a LCD display without additional external components.

Figure 120. Clock Output Values

Crystal Frequency	Clock Output Divider							
	2	2.5	3	4	5	20	80	312.5
10.24 MHz	5.120 MHz	4.096 MHz	3.413 MHz	2.560 MHz	2.048 MHz	512 kHz	128 kHz	32.768 kHz
11.15 MHz	5.575 MHz	4.460 MHz	3.717 MHz	2.788 MHz	2.230 MHz	557 kHz	139 kHz	35.680 kHz
12.00 MHz	6.000 MHz	4.800 MHz	4.000 MHz	3.000 MHz	2.400 MHz	600 kHz	150 kHz	38.400 kHz

## MC13110A MC13111A

**Figure 121. Clock Output Divider**

0	0	0	2
0	0	1	3
0	1	0	4
0	1	1	5
1	0	0	2.5
1	0	1	20
1	1	0	80
1	1	1	312.5

*MPU “Clk Out” Power-Up Default Divider Value*

The power-up default divider value is “divide by 5”. This provides a MPU clock of about 2.0 MHz after initial power-up. The reason for choosing a relatively low clock frequency at initial power-up is because some microprocessors operate using a 3.0 V power supply and have a maximum clock frequency of 2.0 MHz. After initial power-up, the MPU can change the clock divider value and set the clock to the desired operating frequency. Special care was taken in the design of the clock divider to insure that the

transition between one clock divider value and another is “smooth” (i.e. there will be no narrow clock pulses to disturb the MPU).

*MPU “Clk Out” Radiated Noise on Circuit Board*

The clock line running between the MC13110A or MC13111A and the microprocessor has the potential to radiate noise. Problems in the system can occur, especially if the clock is a square wave digital signal with large high frequency harmonics. In order to minimize the radiated noise, a 1000 Ω resistor is included on-chip in series with the “Clk Out” output driver. A small capacitor or inductor with a capacitor can be connected to the “Clk Out” line on the PCB to form a one or two pole low pass filter. This filter should significantly reduce noise radiated by attenuating the high frequency harmonics on the signal line. The filter can also be used to attenuate the signal level so that it is only as large as required by the MPU clock input. To further reduce radiated noise, the PCB signal trace length should be kept to a minimum.

*Volume Control Programming*

The volume control adjustable gain block can be programmed in 2 dB gain steps from -14 dB to +16 dB. The power-up default value for the MC13110A and MC13111A is 0 dB. (see Figure 122)

## MC13110A MC13111A

### Gain Control Register

The gain control register contains bits which control the  $T_X$  Voltage Gain,  $R_X$  Voltage Gain, and Carrier Detect threshold. Operation of these latch bits are explained in Figures 123, 124 and 125.

### $T_X$ and $R_X$ Gain Programming

The  $T_X$  and  $R_X$  audio signal paths each have a programmable gain block. If a  $T_X$  or  $R_X$  voltage gain, other

than the nominal power-up default, is desired, it can be programmed through the MPU interface. Alternately, these programmable gain blocks can be used during final test of the telephone to electronically adjust for gain tolerances in the telephone system (see Figure 124). In this case, the  $T_X$  and  $R_X$  gain register values should be stored in ROM during final test so that they can be reloaded each time the IC is powered up.

## MC13110A MC13111A

### Carrier Detect Threshold Programming

The "CD Out" pin gives an indication to the microprocessor if a carrier signal is present on the selected channel. The nominal value and tolerance of the carrier detect threshold is given in the carrier detect specification section of this document. If a different carrier detect threshold value is desired, it can be programmed through the MPU interface as shown in Figure 125 below. Alternately, the carrier detect threshold can be electronically adjusted during final test of the telephone to reduce the tolerance of the carrier detect

threshold. This is done by measuring the threshold and then by adjusting the threshold through the MPU interface. In this case, it is necessary to store the carrier detect register value in ROM so that the CD register can be reloaded each time the combo IC is powered up. If a preamp is used before the first mixer it may be desirable to scale the carrier detect range by connecting an external resistor from the "RSSI" pin to ground. The internal resistor is 187 kΩ.

**Figure 125. Carrier Detect Threshold Control**

## MC13110A MC13111A

### Clock Divider/Voltage Adjust Register

This register controls the divider value for the programmable switched capacitor filter clock divider, the low battery detect threshold select, the voltage reference adjust, and the scrambler bypass mode (MC13110A only). Operation is explained in Figures 126 through 133. Figure 128 describes the operation of the Tx and Rx Audio bits. Note the power-up default bit is set to <0>, which is the scrambler bypass mode.

### Low Battery Detect

The low battery detect circuit can be operated in programmable and non-programmable threshold modes.

The non-programmable threshold mode is only available in the 52 QFP package. In this mode, there are two low battery detect comparators and the threshold values are set by external resistor dividers which are connected to the REF1 and REF2 pins. In the programmable threshold mode, several different threshold levels may be selected through the “Low Battery Detect Threshold Register” as shown in Figure 127. The power-on default value for this register is <0,0,0> and is the non-programmable mode. Figure 129 shows equivalent schematics for the programmable and non-programmable operating modes.

## Voltage Reference Adjustment

An internal 1.5 V bandgap voltage reference provides the voltage reference for the “BD<sub>1</sub> Out” and “BD<sub>2</sub> Out” low battery detect circuits, the “PLL V<sub>ref</sub>” voltage regulator, the “V<sub>B</sub>” reference, and all internal analog ground references. The initial tolerance of the bandgap voltage reference is ±6%. The tolerance of the internal reference voltage can be improved to ±1.5% through MPU serial interface programming. During final test of the telephone, the battery detect threshold is measured. Then, the internal reference voltage value is adjusted electronically through the MPU serial interface to achieve the desired accuracy level. The voltage reference register value should be stored in ROM during final test so that it can be reloaded each time the MC13110A or MC13111A is powered up (see Figure 130).

**Figure 130. Bandgap Voltage Reference Adjustment**

## Switched Capacitor Filter Clock Programming

A block diagram of the switched capacitor filter clock divider is shown in Figure 131. There is a fixed divide by 2 after the programmable divider. The switched capacitor filter clock value is given by the following equation;

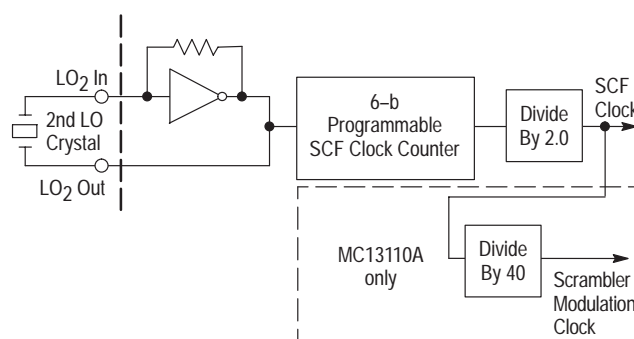

$$(\text{SCF Clock}) = F(2\text{nd LO}) / (\text{SCF Divider Value} * 2).$$

The scrambler modulation clock frequency (SMCF) is proportional to the SCF clock. The following equation defines its value:

$$\text{SMCF} = (\text{SCF Clock})/40$$

The SCF divider should be set to a value which brings the SCF Clock as close to 165.16 kHz as possible. This is based on the 2nd LO frequency which is chosen in Figure 114.

**Figure 131. SCF Clock Divider Circuit**

## Corner Frequency Programming for MC13110A and MC13111A

Four different corner frequencies may be selected by programming the SCF Clock divider as shown in Figures 132 and 133. It is important to note, that all filter corner frequencies will change proportionately with the SCF Clock Frequency and Scrambler Modulation Frequency. The power-up default SCF Clock divider value is 31.

### Auxiliary Register

The auxiliary register contains a 4-bit First LO Capacitor Selection latch and a 3-bit Test Mode latch. Operation of these latch bits are explained in Figures 134, 135 and 136.

### Test Modes

Test modes are selected through the 3-bit Test Mode Register. In test mode, the "T<sub>x</sub> VCO" input pin is multiplexed to the input of the counter under test. The output of the counter under test is multiplexed to the "Clk Out" output pin so that each counter can be individually tested. **Make sure test mode bits are set to "0's" for normal operation.** Test mode operation is described in Figure 135. During normal operation, the "T<sub>x</sub> VCO" input can be a minimum of 200 mVpp at 80 MHz and should be AC coupled. Input signals should be standard logic levels of 0 to 2.5 V and a maximum frequency of 16 MHz.

### First Local Oscillator Programmable Capacitor Selection

There is a very large frequency difference between the minimum and maximum channel frequencies in the 25 Channel U.S. standard. The internal varactor adjustment

range is not large enough to accommodate this large frequency span. An internal capacitor with 15 programmable capacitor values can be used to cover the 25 channel frequency span without the need to add external capacitors and switches. The programmable internal capacitor can also be used to eliminate the need to use an external variable capacitor to adjust the 1st LO center frequency during telephone assembly. Figure 32 shows the schematic of the 1st LO tank circuit. Figure 136 shows the register control bit values.

The internal programmable capacitor is composed of a matrix bank of capacitors that are switched in as desired. Programmable capacitor values between about 0 and 16 pF can be selected in steps of approximately 1.1 pF. The internal parallel resistance values in the table can be used to calculate the quality factor (Q) of the oscillator if the Q of the external inductor is known. The temperature coefficient of the varactor is 0.08%/°C. The temperature coefficient of the internal programmable capacitor is negligible. Tolerance on the varactor and programmable capacitor values is  $\pm 15\%$ .

## OTHER APPLICATIONS INFORMATION

### PCB Board Lay-Out Considerations

The ideal printed circuit board (PCB) lay out would be double-sided with a full ground plane on one side. The ground plane would be divided into separate sections to prevent any audio signal from feeding into the first local oscillator via the ground plane. Leaded components, can likewise, be inserted on the ground plane side to improve shielding and isolation from the circuit side of the PCB. The opposite side of the PCB is typically the circuit side. It has the interconnect traces and surface mount components. In cases where cost allows, it may be beneficial to use multi-layer boards to further improve isolation of components and sensitive sections (i.e. RF and audio). For the CT-0 band, it is also permissible to use single-sided PC layouts, but with continuous full ground fill in and around the components.

The proper placement of certain components specified in the application circuit may be very critical. In a lay-out design, these components should be placed before the other less critical components are inserted. It is also imperative that all RF paths be kept as short as possible. Finally, the MC13110A and MC13111A ground pins should be tied to ground at the pins and VCC pins should have adequate decoupling to ground as close to the IC as possible. In mixed mode systems where digital and RF/Analog circuitry are present, the VCC and VEE buses need to be ac-decoupled and isolated from each other. The design must also take great caution to avoid interference with low level analog circuits. The receiver can be particularly susceptible to interference as they respond to signals of only a few microvolts. Again, be sure to keep the dc supply lines for the digital and analog portions separate. Avoid ground paths carrying common digital and analog currents, as well.

### Component Selection

The evaluation circuit schematics specify particular components that were used to achieve the results shown in the typical curves and tables, but alternate components should give similar results. The MC13110A and MC13111A IC are capable of matching the sensitivity, IMD, adjacent channel rejection, and other performance criteria of a multi-chip analog cordless telephone system. For the most part, the same external components are used as in the multi-chip solution.

### VB and PLL V<sub>ref</sub>

VB is an internally generated bandgap voltage. It functions as an ac reference point for the operational amplifiers in the audio section as well as for the battery detect circuitry. This pin needs to be sufficiently filtered to reduce noise and prevent crosstalk between R<sub>x</sub> audio to T<sub>x</sub> audio signal paths. A practical capacitor range to choose that will minimize crosstalk and noise relative to start up time is 0.5  $\mu$ F to 10  $\mu$ F. The start time for a 0.5  $\mu$ F capacitor is approximately 5.0 ms, while a 10 $\mu$ F capacitor is about 10 ms.

The "PLL V<sub>ref</sub>" pin is the internal supply voltage for the R<sub>x</sub> and T<sub>x</sub> PLL's. It is regulated to a nominal 2.5 V. The "VCC Audio" pin is the supply voltage for the internal voltage regulator. Two capacitors with 10  $\mu$ F and 0.01  $\mu$ F values must be connected to the "PLL V<sub>ref</sub>" pin to filter and stabilize this regulated voltage. The "PLL V<sub>ref</sub>" pin may be used to power other IC's as long as the total external load current does not exceed 1.0 mA. The tolerance of the regulated voltage is initially  $\pm 8.0\%$ , but is improved to  $\pm 4.0\%$  after the internal Bandgap voltage reference is adjusted electronically through the MPU serial interface. The voltage regulator is turned off in the Standby and Inactive modes to reduce current drain. In these modes, the "PLL V<sub>ref</sub>" pin is internally connected to the "VCC Audio" pin (i.e., the power supply voltage is maintained but is now unregulated).

It is important to note that the momentary drop in voltage below 2.5 V during this transition may affect initial PLL lock times and also may trigger the reset. To prevent this, the PLL V<sub>ref</sub> capacitor described above should be kept the same or larger than the VB capacitor, say 10  $\mu$ F as shown in the evaluation and application diagrams.

### DC Coupling

Choosing the right coupling capacitors for the compander is also critical. The coupling capacitors will have an effect on the audio distortion, especially at lower audio frequencies. A useful capacitor range for the compander timing capacitors is 0.1  $\mu$ F to 1.0  $\mu$ F. It is advised to keep the compander capacitors the same value in both the handset and baserset applications.

All other dc coupling capacitors in the audio section will form high pass filters. The designer should choose the overall cut off frequency ( $-3.0$  dB) to be around 200 Hz. Designing for lower cut off frequencies may add unnecessary cost and capacitor size to the design, while selecting too high of a cut off frequency may affect audio quality. It is not necessary or advised to design each audio coupling capacitors for the same cut off frequency. Design for the overall system cut off frequency. (Note: Do not expect the application, evaluation, nor production test schematics to necessarily be the correct capacitor selections.) The goals of these boards may be different than the systems approach a designer must consider.

For the supply pins (VCC Audio and VCC RF) choose a 10  $\mu$ F in parallel with a high quality 0.01  $\mu$ F capacitor. Separation of these two supply planes is essential, too. This is to prevent interference between the RF and audio sections. It is always a good design practice to add additional coupling on each supply plane to ground as well.

The IF limiter capacitors are recommended to be 0.1  $\mu$ F. Smaller values lower the gain of the limiter stage. The  $-3.0$  dB limiting sensitivity and SINAD may be adversely affected.

## APPENDIX C – MEASUREMENT OF COMPANDER ATTACK/DECAY TIME

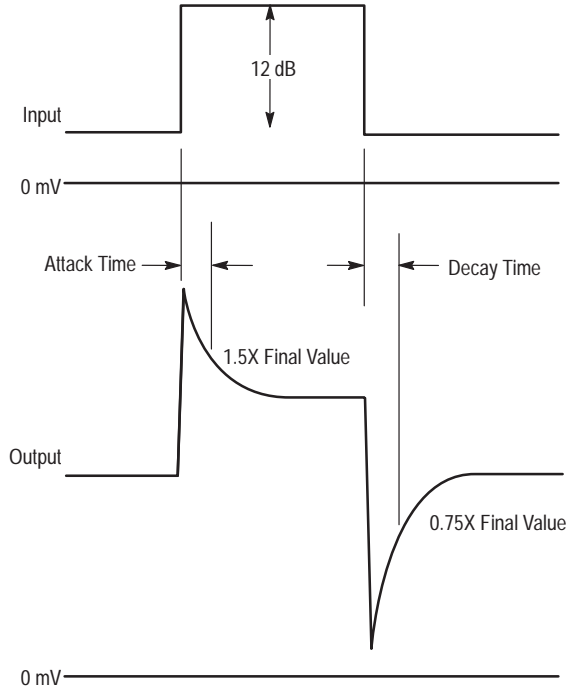

This measurement definition is based on EIA/CCITT recommendations.

### Compressor Attack Time

For a 12 dB step up at the input, attack time is defined as the time for the output to settle to 1.5X of the final steady state value.

### Compressor Decay Time

For a 12 dB step down at the input, decay time is defined as the time for the input to settle to 0.75X of the final steady state value.

### Expander Attack

For a 6.0 dB step up at the input, attack time is defined as the time for the output to settle to 0.57X of the final steady state value.

### Expander Decay

For a 6.0 dB step down at the input, decay time is defined as the time for the output to settle to 1.5X of the final steady state value.

**MOTOROLA**

# FM Communications Receivers

## MC13135 MC13136

The MC13135/MC13136 are the second generation of single chip, dual conversion FM communications receivers developed by Motorola. Major improvements in signal handling, RSSI and first oscillator operation have been made. In addition, recovered audio distortion and audio drive have improved. Using Motorola's MOSAIC™ 1.5 process, these receivers offer low noise, high gain and stability over a wide operating voltage range.

Both the MC13135 and MC13136 include a Colpitts oscillator, VCO tuning diode, low noise first and second mixer and LO, high gain limiting IF, and RSSI. The MC13135 is designed for use with an LC quadrature detector and has an uncommitted op amp that can be used either for an RSSI buffer or as a data comparator. The MC13136 can be used with either a ceramic discriminator or an LC quad coil and the op amp is internally connected for a voltage buffered RSSI output.

These devices can be used as stand-alone VHF receivers or as the lower IF of a triple conversion system. Applications include cordless telephones, short range data links, walkie-talkies, low cost land mobile, amateur radio receivers, baby monitors and scanners.

- Complete Dual Conversion FM Receiver – Antenna to Audio Output
- Input Frequency Range – 200 MHz
- Voltage Buffered RSSI with 70 dB of Usable Range
- Low Voltage Operation – 2.0 to 6.0 Vdc (2 Cell NiCad Supply)
- Low Current Drain – 3.5 mA Typ
- Low Impedance Audio Output < 25 Ω
- VHF Colpitts First LO for Crystal or VCO Operation
- Isolated Tuning Diode
- Buffered First LO Output to Drive CMOS PLL Synthesizer

# MC13135 MC13136

## TEST CIRCUIT INFORMATION

Although the MC13136 can be operated with a ceramic discriminator, the recovered audio measurements for both the MC13135 and MC13136 are made with an LC quadrature detector. The typical recovered audio will depend on the external circuit; either the Q of the quad coil, or the RC matching network for the ceramic discriminator. On the MC13136, an external capacitor between Pins 13 and 14 can be used with a quad coil for slightly higher recovered audio. See Figures 10 through 13 for additional information.

Since adding a matching circuit to the RF input increases the signal level to the mixer, the third order intercept (TOI) point is better with an unmatched input (50 Ω from Pin 21 to Pin 22). Typical values for both have been included in the Electrical Characterization Table. TOI measurements were taken at the pins with a high impedance probe/spectrum analyzer system. The first mixer input impedance was measured at the pin with a network analyzer.

## CIRCUIT DESCRIPTION

The MC13135/13136 are complete dual conversion receivers. They include two local oscillators, two mixers, a limiting IF amplifier and detector, and an op amp. Both provide a voltage buffered RSSI with 70 dB of usable range, isolated tuning diode and buffered LO output for PLL operation, and a separate  $V_{CC}$  pin for the first mixer and LO. Improvements have been made in the temperature performance of both the recovered audio and the RSSI.

### V<sub>CC</sub>

Two separate  $V_{CC}$  lines enable the first LO and mixer to continue running while the rest of the circuit is powered down. They also isolate the RF from the rest of the internal circuit.

### Local Oscillators

The local oscillators are grounded collector Colpitts, which can be easily crystal-controlled or VCO controlled with the on-board varactor and external PLL. The first LO transistor is internally biased, but the emitter is pinned-out and  $I_Q$  can be increased for high frequency or VCO operation. The collector is not pinned out, so for crystal operation, the LO is generally limited to 3rd overtone crystal frequencies; typically around 60 MHz. For higher frequency operation, the LO can be provided externally as shown in Figure 16.

### Buffer

An amplifier on the 1st LO output converts the single-ended LO output to a differential signal to drive the mixer. Capacitive coupling between the LO and the amplifier minimizes the effects of the change in oscillator current on the mixer. Buffered LO output is pinned-out at Pin 3 for use with a PLL, with a typical output voltage of 320 mV<sub>pp</sub> at  $V_{CC} = 4.0$  V and with a 5.1 k resistor from Pin 3 to ground. As seen in Figure 14, the buffered LO output varies with the supply voltage and a smaller external resistor may be needed for low voltage operation. The LO buffer operates up to 60 MHz, typically. Above 60 MHz, the output at Pin 3 rolls off at approximately 6.0 dB per octave. Since most PLLs require about 200 mV<sub>pp</sub> drive, an external amplifier may be required.

Figure 14. Buffered LO Output Voltage versus Supply Voltage

### Mixers

The first and second mixer are of similar design. Both are double balanced to suppress the LO and input frequencies to give only the sum and difference frequencies out. This configuration typically provides 40 to 60 dB of LO suppression. New design techniques provide improved mixer linearity and third order intercept without increased noise. The gain on the output of the 1st mixer starts to roll off at about 20 MHz, so this receiver could be used with a 21 MHz first IF. It is designed for use with a ceramic filter, with an output impedance of 330 Ω. A series resistor can be used to raise the impedance for use with a crystal filter, which typically has an input impedance of 4.0 kΩ. The second mixer input impedance is approximately 4.0 kΩ; it requires an external 360 Ω parallel resistor for use with a standard ceramic filter.

### Limiting IF Amplifier and Detector

The limiter has approximately 110 dB of gain, which starts rolling off at 2.0 MHz. Although not designed for wideband operation, the bandwidth of the audio frequency amplifier has been widened to 50 kHz, which gives less phase shift and enables the receiver to run at higher data rates. However, care should be taken not to exceed the bandwidth allowed by local regulations.

The MC13135 is designed for use with an LC quadrature detector, and does not have sufficient drive to be used with a ceramic discriminator. The MC13136 was designed to use a ceramic discriminator, but can also be run with an LC quad coil, as mentioned in the Test Circuit Information section. The data shown in Figures 12 and 13 was taken using a muRata CDB455C34 ceramic discriminator which has been specially matched to the MC13136. Both the choice of discriminators and the external matching circuit will affect the distortion and recovered audio.

### RSSI/Op Amp

The Received Signal Strength Indicator (RSSI) on the MC13135/13136 has about 70 dB of range. The resistor needed to translate the RSSI current to a voltage output has been included on the internal circuit, which gives it a tighter tolerance. A temperature compensated reference current also improves the RSSI accuracy over temperature. On the MC13136, the op amp on board is connected to the output to provide a voltage buffered RSSI. On the MC13135, the op amp is not connected internally and can be used for the RSSI or as a data slicer (see Figure 17c).

## Low Power Integrated Receiver for ISM Band Applications

The MC13145 is a dual conversion integrated RF receiver intended for ISM band applications. It features a Low Noise Amplifier (LNA), two 50 Ω linear Mixers with linearity control, Voltage Controlled Oscillator (VCO), second LO amplifier, divide by 64/65 dual modulus Prescaler, split IF Amplifier and Limiter, RSSI output, Coillless FM/FSK Demodulator and power down control. Together with the transmit chip (MC13146) and the baseband chip (MC33410 or MC33411A/B), a complete 900 MHz cordless phone system can be implemented. This device may be used in applications up to 1.8 GHz.

## CIRCUIT DESCRIPTION

### General

The MC13145 is a low power dual conversion wideband FM receiver incorporating a split IF. This device is designated for use as the receiver in analog and digital FM systems such as 900 Mhz ISM Band Cordless phones and wideband data links with data rates up to 150kbps. It contains a 1st and 2nd mixer, 1st and 2nd local oscillator, Received Signal Strength Indicator (RSSI), IF amplifier, limiting IF, a unique coilless quadrature detector, and a device enable function.

### Current Regulation/Enable

The MC13145 is designed for battery powered portable applications. Supply current is typically 27 mA at 3.6 Vdc.

Temperature compensating, voltage independent current regulators are controlled by the Enable Pin where "high" powers up and "low" powers down the entire circuit.

### Low Noise Amplifier (LNA)

The LNA is a cascoded common emitter amplifier configuration. Under very large RF input signals, the DC base current of the common emitter and cascode transistors can become very significant. To maintain linear operation of the LNA, adequate dc current source is needed to establish the  $2V_{be}$  reference at the base of the RF cascoded transistor and to provide the base voltage on the common emitter transistor. A sensing circuit, together with a current mirror guarantees that there is always sufficient dc base current available for the cascode transistor under all power levels.

### 1st and 2nd Mixer

Each mixer is a double-balanced class AB four quadrant multiplier which may be externally biased for high mixer dynamic range. Mixer input third order intercept point of up to 17 dBm is achieved with only 7.0 mA of additional supply current. The 1st mixer has a single-ended input at  $50 \Omega$  and operates at 1.0 GHz with  $-3.0$  dB of power gain at approximately 100 mVrms LO drive level. The mixers have open collector differential outputs to provide excellent mixer dynamic range and linearity.

### 1st Local Oscillator

The 1st LO has an on-chip transistor which operates with coaxial transmission line and LC resonant elements up to 1.8 GHz. A VCO output is available for multi-frequency operation under PLL synthesizer control.

### RSSI

The received signal strength indicator (RSSI) output is a current proportional to the log of the received signal amplitude. The RSSI current output (Pin 7) is derived by summing the currents from the IF and limiting amplifier stages. An increase in RSSI dynamic range, particularly at higher input signal levels is achieved. The RSSI circuit is designed to provide typically 80 dB of dynamic range with temperature compensation.

Linearity of the RSSI is optimized by using external ceramic bandpass filters which have an insertion loss of 4.0 dB and  $330 \Omega$  source and load impedance.

### IF Amplifier

The first IF amplifier section is composed of three differential stages with the second and third stages

contributing to the RSSI. This section has internal DC feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 40 dB up to 40MHz.

The fixed internal input impedance is  $330 \Omega$ . When using ceramic filters requiring source and load impedances of  $330 \Omega$ , no external matching is necessary. Overall RSSI linearity is dependent on having total midband attenuation of 10 dB (4.0 dB insertion loss plus 6.0 dB impedance matching loss) for the filter. The output of the IF amplifier is buffered and the impedance is  $330 \Omega$ .

### Limiters

The limiter section is similar to the IF amplifier section except that five stages are used with the middle three contributing to the RSSI. The fixed internal input impedance is  $330 \Omega$ . The total gain of the limiting amplifier section is approximately 84 dB. This IF limiting amplifier section internally drives the coilless quadrature detector section.

### Coilless Quadrature Detector

The coilless detector is a unique design which eliminates the conventional tunable quadrature coil in FM receiver systems. The frequency detector implements a phase locked loop with a fully integrated on chip relaxation oscillator which is current controlled and externally adjusted, a bandwidth adjust, and an automatic frequency tuning circuit. The loop filter is external to the chip allowing the user to set the loop dynamics. Two outputs are used: one to deliver the audio signal (detector output) and the other to filter and tune the detector (AFT).

Figure 2. 2nd Mixer NF & Gain versus LO Power

### Evaluation PCB

The evaluation PCB is a versatile board which allows the MC13145 to be configured as a dual-conversion receiver, or to characterize individual operating parameters.

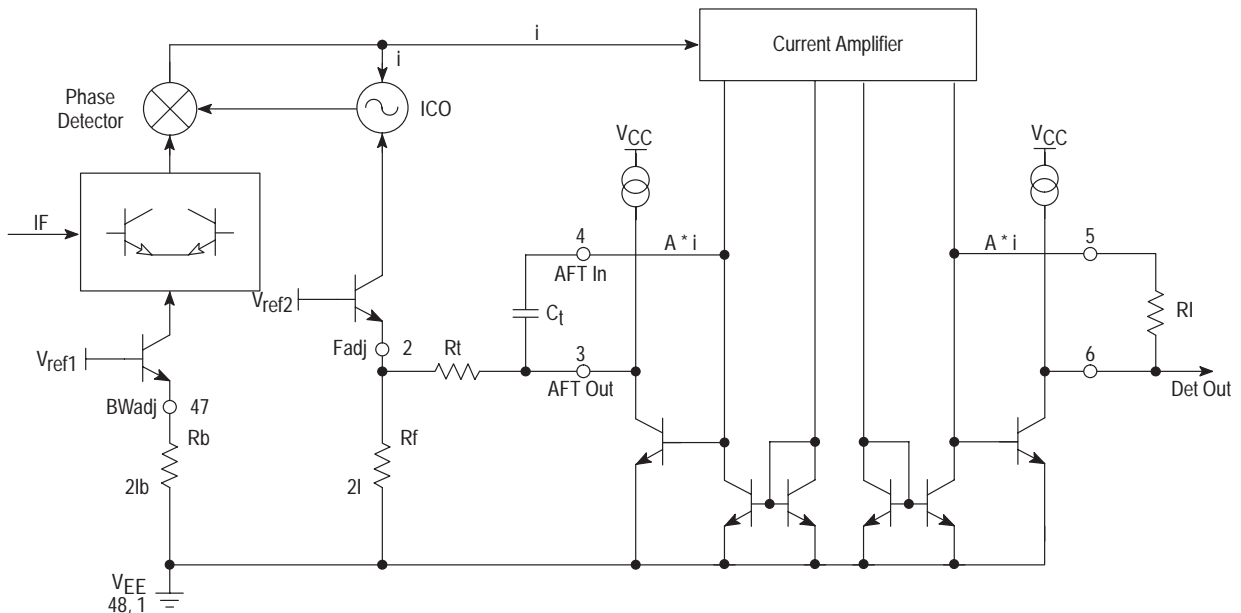

The general purpose schematic and associated parts list for a typical application are given in Figure 15. Please refer to AN1687/D and AN1691/D for additional details and applications for the device.

## PIN FUNCTION DESCRIPTION

Pin	Symbol/Type	Description	Description
47	BWadj	See Figure 3.	<b>COILLESS DETECTOR</b> <b>Bandwidth Adjust</b> The deviation bandwidth of the detector response is determined by the combination of an on-chip capacitor and an external resistor to ground.
2	Fadj		<b>Frequency Adjust</b> The free running frequency of the detector oscillator is defined by the combination of an on-chip capacitor and an external resistor, R <sub>adj</sub> from frequency adjust pin to ground.
1, 48	V <sub>EE</sub>		<b>V<sub>EE</sub>, Negative Supply</b> These pins are V <sub>EE</sub> supply for the coilless detector circuit.
3	AFT Out		<b>AFT Out</b> The AFT is low pass filtered with a corner frequency below the audio bandwidth allowing the error to be added to the center frequency adjust signal at F <sub>adj</sub> , Pin 2. The low frequency high pass corner is set by the external capacitor, C <sub>t</sub> from AFT out (Pin 3) to AFT in (Pin 4) and external resistor, R <sub>t</sub> from AFT out to F <sub>adj</sub> (Pin 2).
4	AFT In		<b>AFT In</b> The AFT in is used to set the buffer transfer function.
5	Det Gain		<b>Detector Gain</b> The AFT buffer is used to set the buffer transfer function.
6	Det Out		<b>Detector Output</b> Set gain and output level of detector with resistor to Det Out Pin.

Figure 3. Coilless Detector Internal Circuit

Pin	Symbol/Type	Description	Description
8	V <sub>EE</sub>		<b>V<sub>EE</sub>, Negative Supply Voltage</b>
9	PRSCout		<b>Prescaler Output</b> The prescaler output provides typically 500 mVpp drive to the fin pin of a PLL synthesizer. Conjugately matching the interface will increase the drive delivered to the PLL input.
10	MC		<b>Dual Modulus Control Current Input</b> This requires a current input of typically 200 μApp.
11, 12	V <sub>CC</sub>		<b>V<sub>CC</sub>, Positive Supply</b> V <sub>CC</sub> pin is taken to the incoming positive battery or regulated dc voltage through a low impedance trace on the PCB. It decoupled to V <sub>EE</sub> ground at the pin of the IC.
14	LNA In		<b>LNA In</b> The input is the base of the common emitter transistor. Minimum external matching is required to optimize the input return loss and gain.
13, 15, & 16	V <sub>EE</sub>		<b>V<sub>EE</sub>, Negative Supply</b> V <sub>EE</sub> pin is taken to an ample dc ground plane through a low impedance path. The path should be kept as short as possible. A minimum two sided PCB is recommended so that ground returns can be easily made through via holes.
17	LNAout		<b>LNA Out</b> The output is from the collector of the cascode transistor amplifier. The output may be conjugately matched with a shunt L (needed to dc bias the open collector), and series L and C network.
19	Mxr <sub>1</sub> In		
20	Lin Adj1	<b>1st Mixer Linearity Control</b> The mixer linearity control circuit accepts approximately 0 to 300 μA control current to set the dynamic range of the mixer. An Input Third Order Intercept Point, IIP3 of 17 dBm may be achieved at 300 μA of control current.

### Input Matching / Components

It is desirable to use a RF ceramic or SAW filter before the mixer to provide image frequency rejection. The filter is selected based on cost, size and performance tradeoffs. Typical RF filters have 1.5 to 2.5 dB insertion loss. The evaluation PC board layout accommodates ceramic RF filters which are offered by various suppliers.

Interface matching between the LNA, RF filter and the mixer will be required. The interface matching networks shown in the evaluation circuit are designed for 50  $\Omega$  interfaces.

### 1st Mixer Output & 2nd Mixer Input Interface Matching

In a wideband system the primary sensitivity of the receiver backend may be achieved before the last mixer. The evaluation circuit shows the matching and impedance transformation network between the 1st mixer open collector differential outputs and 2nd mixer single ended 50 ohm input. This adjustable shielded transformer and tapped capacitor transform network does two things: 1) bandpass limits the 1st IF signal with a loaded Q of approximately 40 and 2) provides adequate second image rejection and a low cost alternative to a SAW filter.

However, a SAW filter may be selected as a more costly alternative while providing improved 2nd image rejection and a fixed tuned 1st IF filter.

### 2nd Mixer & Limiting IF Matching / Filtering

A simple LCR network is needed to interface the 2nd mixer differential outputs to 330 ohm ceramic filters or directly to the 330 ohm IF input. TDK, Toko and Murata offer single 10.7 MHz ceramic filters with various 3.0 dB bandwidths from 110 to 380 kHz. Murata offers a series-parallel resonator pair (part number KMFC545) with a 3.0 dB bandwidth of  $\pm 325$  kHz and a maximum insertion loss of 5.0 dB. However, even the series-parallel ceramic filter pair yields only a maximum bandpass of 650 kHz. In some data applications a wider band IF bandpass is necessary.

### Local Oscillators – VHF/UHF Applications

The on-chip transistor may be used for HF and VHF local oscillator with higher order overtone crystals. It is recommended that a Butler overtone oscillator configuration is used. The crystal is driven from the emitter and is coupled to the high impedance base through a capacitive tap network. Operation at the desired overtone frequency is ensured by the parallel resonant circuit formed by an inductor and the tap capacitors and parasitic capacitances of the on-chip transistor and PC board. A high tolerance, high Q ceramic or air wound surface mount component may be used if the other components have tight enough tolerances; however, a variable inductor provides an adjustment for gain and frequency of the resonant tank ensuring lock up and start-up of the crystal oscillator. The overtone crystal is chosen with ESR of typically 80 ohms and 120 ohms maximum; if the resistive loss in the crystal is too high the performance of oscillator may be impacted by lower gain margins.

A series LC network to ac ground (which is  $V_{CC}$ ) is comprised of the inductance of the base lead of the on-chip transistor and PC board traces and tap capacitors. Parasitic oscillations often occur in the 200 to 900 MHz range. A small resistor is placed in series with the base (pin 9) to cancel the

negative resistance associated with this undesired mode of oscillation. Since the base input impedance is so large a small resistor in the range of 27 to 68 ohms has very little effect on the desired Butler mode of oscillation.

The crystal parallel capacitance,  $C_O$ , provides a feedback path that is low enough in reactance at frequencies of 5th overtones or higher to cause trouble.  $C_O$  has little effect near resonance because of the low impedance of the crystal motional arm ( $R_m-L_m-C_m$ ). As the tunable inductor which forms the resonant tank with the tap capacitors is tuned off the crystal resonant frequency it may be difficult to tell if the oscillation is under crystal control. Frequency jumps may occur as the inductor is tuned. In order to eliminate this behavior an inductor,  $L_O$ , is placed in parallel with the crystal.  $L_O$  is chosen to be resonant with the crystal parallel capacitance,  $C_O$ , at the desired operation frequency. The inductor provides a feedback path at frequencies well below resonance; however, the parallel tank network of the tap capacitors and tunable inductor prevent oscillation at these frequencies.

### Coilless Detector

The coilless detector (see Figure 3) is unique and offers cost and performance advantages over the conventional quadrature detector. It consists of a current controlled oscillator (ICO) and a phase detector. The error current,  $I$  is also amplified to provide an output, and the output is duplicated and filtered and fed back to the oscillator to provide automatic fine tuning (AFT).

The oscillator free running frequency,  $f_o$  is set by  $R_f$  and is calculated by the following equation where  $C$  is approximately 4.0 pF:

$$f_o = 1/(8 \cdot R_f \cdot C)$$

The demodulator bandwidth is set by  $R_b$  and is shown in Figure 14.

The AFT is filtered by  $C_t$  and  $R_t$ . The low pass pole creates a high pass pole in the overall demodulator frequency response at:

$$A/(2 \cdot \pi \cdot C_t \cdot R_t)$$

where  $A$ , the current gain = 10.

Typical coilless detector output level is:

$$V_{out}(\text{peak}) = (f_{\text{peak dev}}/f_{IF}) \cdot A \cdot i \cdot R_I$$

For example, if peak deviation is 25 kHz,  $i = 250 \mu\text{A}$  at  $f_{IF} = 10.7 \text{ MHz}$ , and  $R_I$  is 50 k $\Omega$ ; then  $V_{out}$  is 292 mVp or 584 mVpp.

The AFT Out pin is capable of voltage swings from about 300 mV to  $V_{CC} - 300 \text{ mV}$ . At these extreme values, the AFT circuit can become saturated and very long detector lock-up times may be observed. It is best, therefore, to limit the AFT Out swing from about 500 mV to  $V_{CC} - 500 \text{ mV}$  and attempt to center the AFT Out voltage at  $V_{CC}/2$  for a detector lock condition.

As an example, for  $V_{CC} = 2.7 \text{ V}$ , the ideal AFT Out voltage at lock would be 1.35 V, with an available swing of 0.5 V to 2.2 V (1.7 V total). If the AFT tuning range is to be  $\pm 500 \text{ kHz}$ , this corresponds to an adjustment current of  $1.0 \text{ MHz}/f_{IF} \cdot i$ . From Figure 11, to set  $f_{IF}$  at 10.7 MHz,  $i$  is approximately 240  $\mu\text{A}$ , and the total adjustment current range is therefore about 22.4  $\mu\text{A}$  over a 1.7 V total swing, or  $R_t = 75.9 \text{ k}$ . At lock,

# MC13145

current equaling  $(AFT\ Out - F_{adj})/R_t$  will be flowing into the  $F_{adj}$  node. This current then is approximately  $(1.35\ V -$

$0.7\ V)/75.9\ k\Omega$  or  $8.6\ \mu A$ . The  $F_{adj}$  resistor,  $R_f$ , is therefore equal to  $0.7\ V/(240\ \mu A + 8.6\ \mu A)$  or about  $2.82\ k\Omega$ .

## Low Power Integrated Transmitter for ISM Band Applications

The MC13146 is an integrated RF transmitter targeted at ISM band applications. It features a 50 Ω linear Mixer with linearity control, voltage controlled oscillator, divide by 64/65 dual modulus Prescaler and Low Power Amplifier (LPA). Together with the receiver chip (MC13145) and either baseband chip (MC33410 or MC33411A/B), a complete 900 MHz cordless phone system can be implemented. This device may be used in applications up to 1.8 GHz.

- Low Distortion LPA:  $P_{out\_1\text{ dB Compression Point}} \approx 10\text{ dBm}$
- High Mixer Linearity:  $IIP3 = 10\text{ dBm}$
- 50 Ω Mixer Input Impedance
- Differential Open Collector Mixer Output
- Low Power 64/65 Dual Modulus Prescaler (MC12054 type)
- 2.7 to 6.5 V Operation, Low Current Drain (25 mA @ 2.0 GHz)
- Powerdown Mode:  $<60\ \mu\text{A}$
- Usable up to 1.8 GHz

## MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Power Supply Voltage	$V_{CC(max)}$	7.0	Vdc
Junction Temperature	$T_J(max)$	150	°C
Storage Temperature Range	$T_{stg}$	-65 to 150	°C

- NOTES:** 1. Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Recommended Operating Conditions, Electrical Characteristics tables or Pin Descriptions section.  
2. Meets Human Body Model (HBM)  $\leq 100$  V and Machine Model (MM)  $\leq 25$  V. ESD data available upon request.

## RECOMMENDED OPERATING CONDITIONS

Characteristic	Symbol	Min	Typ	Max	Unit
Power Supply Voltage ( $T_A = 25^\circ\text{C}$ )	$V_{CC}$ $V_{EE}$	2.7 -	- 0	6.5 -	Vdc Vdc
RF Frequency Range	$f_{RF}$	1.0	-	2500	MHz
Ambient Temperature Range	$T_A$	-20	-	70	°C
Maximum Input Signal Level	$P_{IF}$	-	-10	-	dBm
- with no damage		-	15	-	dBm
- with minor performance degradation		-		-	

## TRANSMITTER DC ELECTRICAL CHARACTERISTICS ( $T_A = 25^\circ\text{C}$ , $V_{CC} = 3.6$ Vdc, no input signal, unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
Total Supply Current (Enable = $V_{CC}$ )	$I_{total}$	15	18	21	mA
Power Down Current (Enable = $V_{EE}$ )	$I_{total}$	-	30	100	$\mu\text{A}$
MC Current Input (High)	$I_{ih}$	70	100	130	$\mu\text{A}$
MC Current Input (Low)	$I_{il}$	-130	-100	-70	$\mu\text{A}$

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol/Type	Description	Description
13	V <sub>CC</sub>		<b>V<sub>CC</sub>, Supply Voltage</b>
14	PRSC Out		<b>Prescaler Output</b> The prescaler output provides 500 mVpp drive to the F <sub>in</sub> Pin of a PLL synthesizer. Conjugately matching the interface will increase the drive delivered to the PLL input.
15	V <sub>EE</sub>		<b>V<sub>EE</sub>, Negative Supply</b>
16	MC		<b>Dual Modulus Control Current Input</b> This requires a current input of typically 200 μApp.
17	Enable		<b>Transmitter Enable</b> Enable the transmitter by pulling the pin up to V <sub>CC</sub> .
19	PA <sub>out</sub>		<b>PA Out</b> The output is an open collector of the cascode transistor low power amplifier (LPA); it is externally biased. The output may be conjugately matched with a shunt L, and series L and C network.
20, 21	V <sub>EE</sub>		<b>V<sub>EE</sub>, Negative Supply</b> V <sub>EE</sub> pin is taken to an ample dc ground plane through a low impedance path. The path should be kept as short as possible. A two sided PCB is implemented so that ground returns can be easily made through via holes.
22	PA <sub>in</sub>		<b>PA In</b> The input is the base of the common emitter transistor. Minimum external matching is required to optimize the input return loss and gain.
23	V <sub>CC</sub>		<b>V<sub>CC</sub>, Positive Supply</b> V <sub>CC</sub> pin is taken to the incoming positive battery or regulated dc voltage through a low impedance trace on the PCB. It is decoupled to V <sub>EE</sub> ground at the pin of the IC.

# MC13146

## CIRCUIT DESCRIPTION

### General

The MC13146 consists of a low power amplifier, a 50 Ω linear mixer with linearity control, divide by 64/65 dual modulus prescaler and LPA. This device is designated for use as the low power transmitter in analog and digital FM systems such as UHF and 800 MHz Special Mobile Radio (SMR), UHF Family Radio Services, PCS and 902 to 928 MHz cordless telephones. It features a mixer linearity control to preset or auto program the mixer dynamic range, an enable function and a wideband mixer output so the IC may be used either as an upconverter or for a direct conversion source. Additional details are covered in the Pin by Pin Description which shows the equivalent internal circuit and external circuit requirements.

### Current Regulation/Enable

The device features temperature compensating, voltage independent current regulators which are controlled by the enable function in which "high" powers up the IC.

### Mixer: General

The mixer is a double-balanced four quadrant multiplier biased class AB allowing for programmable linearity control via an external current source. An input third order intercept point of 20 dBm has been achieved. The mixer has a 50 Ω single-ended RF input and open collector differential outputs. An onboard Local Oscillator transistor has the emitter, base and collector pinned out to implement a low phase noise VCO in various configurations. Additionally, a buffered prescaler output is provided for operation with a low frequency synthesizer. For direct conversion applications the input of the mixer may be terminated to ground through a 120 to 330 Ω resistor.

### Local Oscillator/Voltage Control Oscillator

The on-chip transistor operates with coaxial transmission line or LC resonant elements to over 1.8 GHz. Biasing is done with a temperature/voltage compensated current source in the emitter. A RFC from V<sub>CC</sub> to the base is recommended.

The transistor can be operated in the classic Colpitts, Clapp, or Hartley configuration. The application circuit (Figure 8) depicts a parallel resonant VCO which can cover the entire 902 to 928 MHz frequency band with phase noise of approximately -80 dBc/Hz at a 10 kHz offset (see Figure 2). For this configuration, the LO will be driven with approximately 100 mV<sub>rms</sub>, and the frequency of oscillation can be approximated by:

$$F_{osc} = \frac{1}{\left(2\pi \sqrt{\left(\frac{C1 C2}{C1 + C2}\right)\left(\frac{C3 C_v}{C3 + C_v} + 3.6 \text{ pF}\right)(L1 + 1.8 \text{ nH})}\right)}$$

where C<sub>v</sub> is the equivalent capacitance of the varactor at the control voltage.

For higher frequency operation, a series tuned oscillator configuration is recommended. Table 1 contains the S-parameters for the VCO transistor in a common collector configuration. This information is useful for designing a VCO at other operating frequencies or for various other oscillator topologies.

The output power (at Mix/Buf Out) can be varied by adjusting the value of R5 as illustrated in Figures 3 and 4. Figure 5 shows the typical operating window for the prescaler.

**Figure 2. Typical Tuning Performance**

**Figure 3. Mixer/Buffer Output versus 1st LO Input**

Figure 4. Test Circuit for Figure 3.

Figure 5. Typical Prescaler Operating Window

#### Mixer/Buffer Input

The Mixer/Buf In pin is a broadband, 50  $\Omega$  input used to drive the IF port of the mixer (see Table 2, S11 parameters). The Mixer/Buf In pin can be used in one of three modes:

1. A IF signal can be applied to this pin and up-converted to the desired RF frequency.
2. A resistor can be connected to ground, controlling the RF output power.
3. A resistor can be connected to  $V_{CC}$ , disabling the entire mixer.

The linear gain of the Mixer/Buf when used as a buffer is approximately  $-5.0$  to  $-8.0$  dB.

#### Mixer/Buffer Outputs

The mixer outputs (Mixer/Buf Out + and Mixer/Buf Out  $-$ ) are balanced, open collector. A shunt resistor of 200  $\Omega$  minimum to  $V_{CC}$  is recommended for stability.

The outputs can be used as a single-ended driver or connected in a balanced-to-unbalanced configuration. If the single-ended driver configuration is used, the unused output must be tied directly to  $V_{CC}$ . For the balanced-to-unbalanced configuration, an additional 3.0 to 6.0 dB of power gain can be achieved. Conjugate matching is easily accomplished to the desired load by the addition of a shunt and series element (see Table 2, S22 parameters).

#### Low Power Amplifier (LPA)

The LPA is internally biased at low supply current (approximately 2.0 mA emitter current) for optimal low power operation, yielding a 10 dBm 1.0 dB output power compression point. Input and output matching may be achieved at various frequencies using few external components (see Table 3 S-parameters). Typical power gain is 16 dB with the input/output conjugately matched to the source/load impedance. A minimum 200  $\Omega$  shunt resistor from the output to  $V_{CC}$  is recommended for stability.

## Evaluation PCB

The evaluation PCB is a versatile board which allows the MC13146 to be configured as a basic transmitter, or to characterize individual operating parameters.

The general purpose schematic and associated parts list for the PCB is given in Figure 9. This parts list build-up is

identical to the Test Circuit illustrated in Figure 1, although parameters can vary significantly due to differences in PCB parasitics. Figures 10, 11, and 12 show the actual PCB component, ground and solder sides, respectively.

Please refer to AN1687/D and AN1691/D for additional details and applications for the device.

# MC13150

## Narrowband FM Coilless Detector IF Subsystem

The MC13150 is a narrowband FM IF subsystem targeted at cellular and other analog applications. Excellent high frequency performance is achieved, with low cost, through use of Motorola's MOSAIC 1.5™ RF bipolar process. The MC13150 has an onboard Colpitts VCO for Crystal controlled second LO in dual conversion receivers. The mixer is a double balanced configuration with excellent third order intercept. It is useful to beyond 200 MHz. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. The quadrature detector is a unique design eliminating the conventional tunable quadrature coil.

Applications for the MC13150 include cellular, CT-1 900 MHz cordless telephone, data links and other radio systems utilizing narrowband FM modulation.

- Linear Coilless Detector
- Adjustable Demodulator Bandwidth
- 2.5 to 6.0 Vdc Operation
- Low Drain Current: < 2.0 mA
- Typical Sensitivity of 2.0 μV for 12 dB SINAD
- IIP3, Input Third Order Intercept Point of 0 dBm
- RSSI Range of Greater Than 100 dB
- Internal 1.4 kΩ Terminations for 455 kHz Filters
- Split IF for Improved Filtering and Extended RSSI Range

## MC13150 CIRCUIT DESCRIPTION

### General

The MC13150 is a very low power single conversion narrowband FM receiver incorporating a split IF. This device is designated for use as the backend in analog narrowband FM systems such as cellular, 900 MHz cordless phones and narrowband data links with data rates up to 9.6 k baud. It contains a mixer, oscillator, extended range received signal strength indicator (RSSI), RSSI buffer, IF amplifier, limiting IF, a unique coilless quadrature detector and a device enable function (see Package Pin Outs/Block Diagram).

### Low Current Operation

The MC13150 is designed for battery and portable applications. Supply current is typically 1.7 mAdc at 3.0 Vdc. Figure 2 shows the supply current versus supply voltage.

### Enable

The enable function is provided for battery powered operation. The enabled pin is pulled down to enable the regulators. Figure 3 shows the supply current versus enable voltage,  $V_{enable}$  (relative to  $V_{CC}$ ) needed to enable the device. Note that the device is fully enabled at  $V_{CC} - 1.3$  Vdc. Figure 4 shows the relationship of enable current,  $I_{enable}$  to enable voltage,  $V_{enable}$ .

### Mixer

The mixer is a double-balanced four quadrant multiplier and is designed to work up to 500 MHz. It has a single ended input. Figure 5 shows the mixer gain and saturated output response as a function of input signal drive and for  $-10$  dBm LO drive level. This is measured in the application circuit shown in Figure 15 in which a single LC matching network is used. Since the single-ended input impedance of the mixer is  $200 \Omega$ , an alternate solution uses a 1:4 impedance transformer to match the mixer to  $50 \Omega$  input impedance. The linear voltage gain of the mixer alone is approximately 4.0 dB (plus an additional 6.0 dB for the transformer). Figure 6 shows the mixer gain versus the LO input level for various mixer input levels at 50 MHz RF input.

The buffered output of the mixer is internally loaded, resulting in an output impedance of  $1.5 \text{ k}\Omega$ .

### Local Oscillator

The on-chip transistor operates with crystal and LC resonant elements up to 220 MHz. Series resonant, overtone crystals are used to achieve excellent local oscillator stability. 3rd overtone crystals are used through about 65 to 70 MHz. Operation from 70 MHz up to 200 MHz is feasible using the on-chip transistor with a 5th or 7th overtone crystal. To enhance operation using an overtone crystal, the internal transistor's bias is increased by adding an external resistor from Pin 29 (in 32 pin QFP package) to  $V_{EE}$  to keep the oscillator on continuously or it may be taken to the enable pin to shut it off when the receiver is disabled.  $-10$  dBm of local oscillator drive is needed to adequately drive the mixer (Figure 6). The oscillator configurations specified above are described in the application section.

### RSSI

The received signal strength indicator (RSSI) output is a current proportional to the log of the received signal amplitude. The RSSI current output is derived by summing the currents from the IF and limiting amplifier stages. An external resistor at Pin 25 (in 32 pin QFP package) sets the voltage range or swing of the RSSI output voltage. Linearity of the RSSI is optimized by using external ceramic bandpass filters which have an insertion loss of 4.0 dB. The RSSI circuit is designed to provide 100+ dB of dynamic range with temperature compensation (see Figures 7 and 23 which show the RSSI response of the applications circuit).

### RSSI Buffer

The RSSI buffer has limitations in what loads it can drive. It can pull loads well towards the positive and negative supplies, but has problems pulling the load away from the supplies. The load should be biased at half supply to overcome this limitation.

Figure 2. Supply Current versus Supply Voltage

Figure 3. Supply Current versus Enable Voltage

Figure 4. Enable Current versus Enable Voltage

Figure 5. Mixer IF Output Level versus RF Input Level

Figure 6. Mixer IF Output Level versus Local Oscillator Input Level

Figure 7. RSSI Output Current versus Input Signal Level

**IF Amplifier**

The first IF amplifier section is composed of three differential stages. This section has internal dc feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 42 dB at 455 kHz. Figure 8 shows the gain of the IF amplifier as a function of the IF frequency.

The fixed internal input impedance is 1.5 kΩ; it is designed for applications where a 455 kHz ceramic filter is used and no external output matching is necessary since the filter requires a 1.5 kΩ source and load impedance.

Overall RSSI linearity is dependent on having total midband attenuation of 10 dB (4.0 dB insertion loss plus 6.0 dB impedance matching loss) for the filter. The output of the IF amplifier is buffered and the impedance is 1.5 kΩ.

**Limiter**

The limiter section is similar to the IF amplifier section except that six stages are used. The fixed internal input impedance is 1.5 kΩ. The total gain of the limiting amplifier section is approximately 96 dB. This IF limiting amplifier section internally drives the quadrature detector section.

**Figure 8. IF Amplifier Gain versus IF Frequency**

**Figure 9. F<sub>adj</sub> Current versus IF Frequency**

**Figure 10. F<sub>adj</sub> Voltage versus F<sub>adj</sub> Current**

**Figure 11. BW<sub>adj</sub> Current versus IF Frequency**

**Coilless Detector**

The quadrature detector is similar to a PLL. There is an internal oscillator running at the IF frequency and two detector outputs. One is used to deliver the audio signal and the other one is filtered and used to tune the oscillator.

The oscillator frequency is set by an external resistor at the  $F_{adj}$  pin. Figure 9 shows the control current required for a particular frequency; Figure 10 shows the pin voltage at that current. From this the value of  $R_F$  is chosen. For example, 455 kHz would require a current of around 50  $\mu A$ . The pin voltage (Pin 16 in the 32 pin QFP package) is around 655mV giving a resistor of 13.1 k $\Omega$ . Choosing 12 k $\Omega$  as the nearest standard value gives a current of approximately 55  $\mu A$ . The 5.0  $\mu A$  difference can be taken up by the tuning resistor,  $R_T$ .

The best nominal frequency for the  $AFT_{out}$  pin (Pin 17) would be half supply. A supply voltage of 3.0 Vdc suggests a resistor value of  $(1.5 - 0.655)V/5.0 \mu A = 169 k\Omega$ . Choosing 150 k $\Omega$  would give a tuning current of  $3/150 k = 20 \mu A$ . From Figure 9 this would give a tuning range of roughly 10 kHz/ $\mu A$  or  $\pm 100$  kHz which should be adequate.

The bandwidth can be adjusted with the help of Figure 11. For example, 1.0  $\mu A$  would give a bandwidth of  $\pm 13$  kHz. The

voltage across the bandwidth resistor,  $R_B$  from Figure 12 is  $V_{CC} - 2.44 Vdc = 0.56 Vdc$  for  $V_{CC} = 3.0 Vdc$ , so  $R_B = 0.56V/1.0 \mu A = 560 k\Omega$ . Actually the locking range will be  $\pm 13$  kHz while the audio bandwidth will be approximately  $\pm 8.4$  kHz due to an internal filter capacitor. This is verified in Figure 13. For some applications it may be desirable that the audio bandwidth is increased; this is done by reducing  $R_B$ . Reducing  $R_B$  widens the detector bandwidth and improves the distortion at high input levels at the expense of 12 dB SINAD sensitivity. The low frequency 3.0dB point is set by the tuning circuit such that the product

$$R_T C_T = 0.68/f_{3dB}$$

So, for example, 150 k and 1.0  $\mu F$  give a 3.0 dB point of 4.5 Hz. The recovered audio is set by  $R_L$  to give roughly 50mV per kHz deviation per 100 k of resistance. The dc level can be shifted by  $R_S$  from the nominal 0.68 V by the following equation:

$$\text{Detector DC Output} = ((R_L + R_S)/R_S) 0.68 Vdc$$

Thus,  $R_S = R_L$  sets the output at  $2 \times 0.68 = 1.36 V$ ;  $R_L = 2R_S$  sets the output at  $3 \times 0.68 = 2.0 V$ .

## APPLICATIONS INFORMATION

### Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side (see Figures 29 and 30). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. There is an area dedicated for a LNA preamp. This evaluation board will be discussed and referenced in this section.

### Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers and coil types. The applications circuit schematic (Figure 15) specifies particular components that were used to achieve the results shown in the typical curves but equivalent components should give similar results. Component placement views are

shown in Figures 27 and 28 for the application circuit in Figure 15 and for the 83.616 MHz crystal oscillator circuit in Figure 16.

### Input Matching Components

The input matching circuit shown in the application circuit schematic (Figure 15) is a series L, shunt C single L section which is used to match the mixer input to 50  $\Omega$ . An alternative input network may use 1:4 surface mount transformers or BALUNs. The 12 dB SINAD sensitivity using the 1:4 impedance transformer is typically -100 dBm for  $f_{\text{mod}} = 1.0$  kHz and  $f_{\text{dev}} = \pm 5.0$  kHz at  $f_{\text{in}} = 50$  MHz and  $f_{\text{LO}} = 50.455$  MHz (see Figure 14).

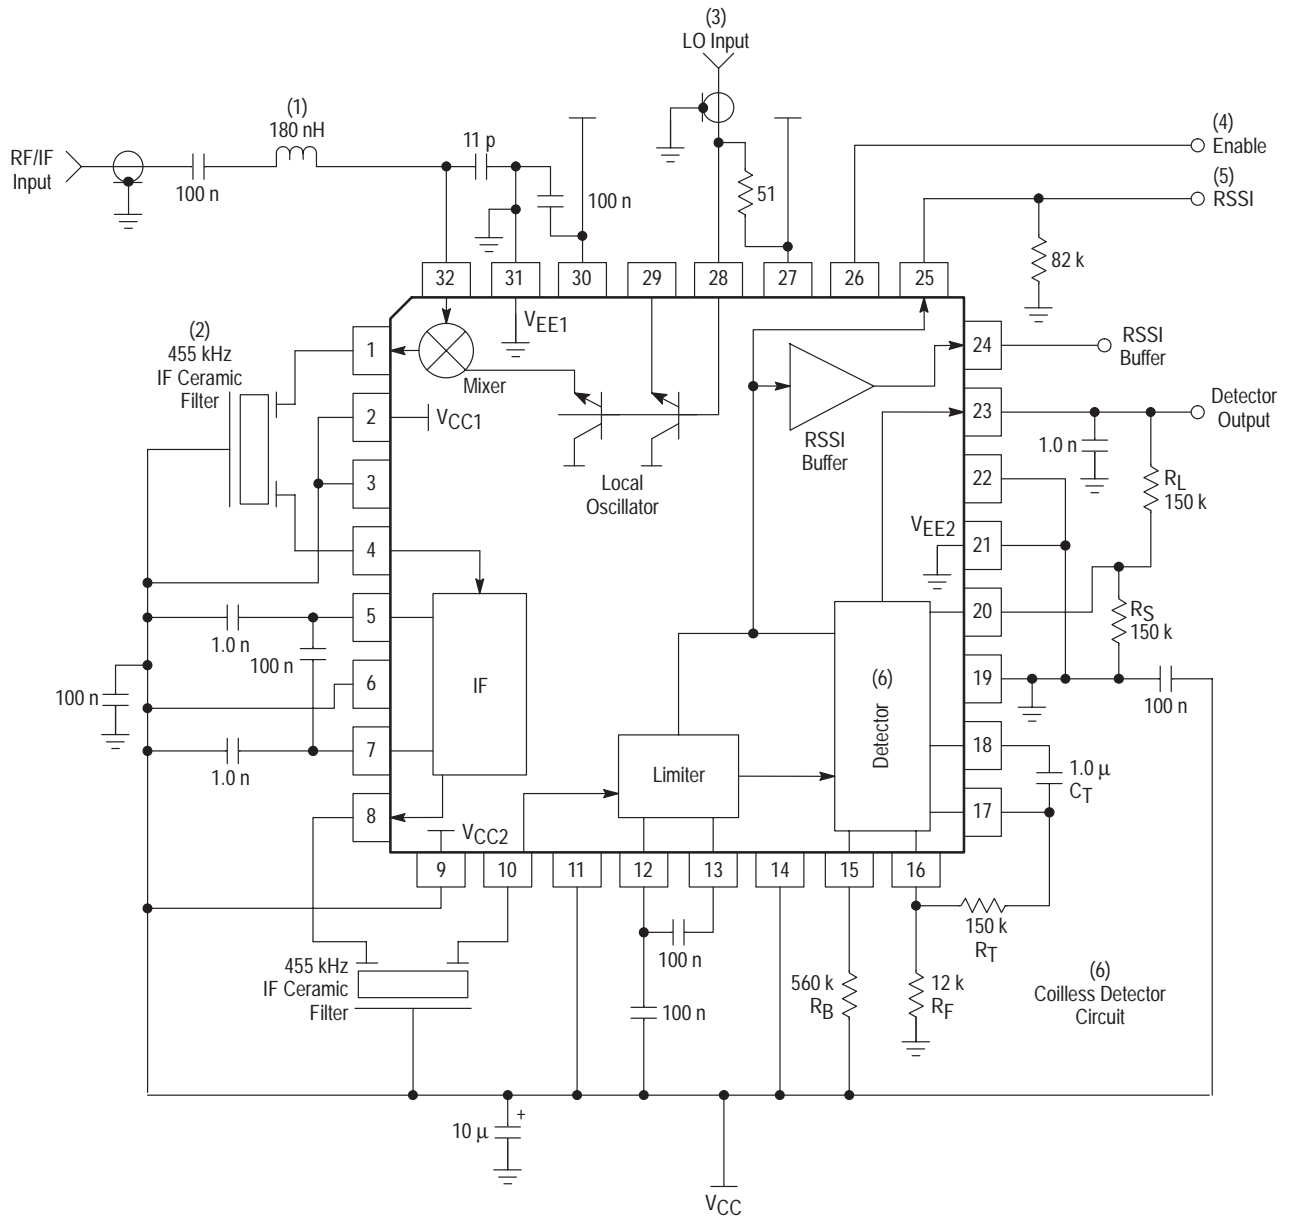

It is desirable to use a SAW filter before the mixer to provide additional selectivity and adjacent channel rejection and improved sensitivity. SAW filters sourced from Toko (Part # SWS083GBWA) and Murata (Part # SAF83.16MA51X) are excellent choices to easily interface with the MC13150 mixer. They are packaged in a 12 pin low profile surface mount ceramic package. The center frequency is 83.161 MHz and the 3.0 dB bandwidth is 30 kHz.

Figure 14. S+N+D, N+D, N, 30% AMR versus Input Signal Level

# MC13150

Figure 15. Application Circuit

- NOTES:**
1. Alternate solution is 1:4 impedance transformer (sources include Mini Circuits, Coilcraft and Toko).
  2. 455 kHz ceramic filters (source Murata CFU455 series which are selected for various bandwidths).
  3. For external LO source, a 51 Ω pull-up resistor is used to bias the base of the on-board transistor as shown in Figure 15. Designer may provide local oscillator with 3rd, 5th, or 7th overtone crystal oscillator circuit. The PC board is laid out to accommodate external components needed for a Butler emitter coupled crystal oscillator (see Figure 16).
  4. Enable IC by switching the pin to V<sub>EE</sub>.
  5. The resistor is chosen to set the range of RSSI voltage output swing.
  6. Details regarding the external components to setup the coilless detector are provided in the application section.

Local Oscillators

HF & VHF Applications

In the application schematic, an external sourced local oscillator is utilized in which the base is biased via a 51 Ω resistor to V<sub>CC</sub>. However, the on-chip grounded collector transistor may be used for HF and VHF local oscillators with higher order overtone crystals. Figure 16 shows a 5th overtone oscillator at 83.616 MHz. The circuit uses a Butler overtone oscillator configuration. The amplifier is an emitter follower. The crystal is driven from the emitter and is coupled to the high impedance base through a capacitive tap network. Operation at the desired overtone frequency is ensured by the parallel resonant circuit formed by the variable inductor and the tap capacitors and parasitic capacitances of the on-chip transistor and PC board. The variable inductor specified in the schematic could be replaced with a high tolerance, high Q ceramic or air wound surface mount component if the other components have tight enough tolerances. A variable inductor provides an adjustment for gain and frequency of the resonant tank ensuring lock up and start-up of the crystal oscillator. The overtone crystal is chosen with ESR of typically 80 Ω and 120 Ω maximum; if the resistive loss in the crystal is too high the performance of oscillator may be impacted by lower gain margins.

A series LC network to ac ground (which is V<sub>CC</sub>) is comprised of the inductance of the base lead of the on-chip transistor and PC board traces and tap capacitors. Parasitic oscillations often occur in the 200 to 800 MHz range. A small resistor is placed in series with the base (Pin 28) to cancel the negative resistance associated with this undesired mode of oscillation. Since the base input impedance is so large, a small resistor in the range of 27 to 68 Ω has very little effect on the desired Butler mode of oscillation.

The crystal parallel capacitance, C<sub>O</sub>, provides a feedback path that is low enough in reactance at frequencies of 5th overtones or higher to cause trouble. C<sub>O</sub> has little effect near resonance because of the low impedance of the crystal motional arm (R<sub>m</sub>-L<sub>m</sub>-C<sub>m</sub>). As the tunable inductor, which forms the resonant tank with the tap capacitors, is tuned off the crystal resonant frequency, it may be difficult to tell if the oscillation is under crystal control. Frequency jumps may occur as the inductor is tuned. In order to eliminate this behavior an inductor, L<sub>O</sub>, is placed in parallel with the crystal. L<sub>O</sub> is chosen to resonant with the crystal parallel capacitance, C<sub>O</sub>, at the desired operation frequency. The inductor provides a feedback path at frequencies well below resonance; however, the parallel tank network of the tap capacitors and tunable inductor prevent oscillation at these frequencies.

## Receiver Design Considerations

The curves of signal levels at various portions of the application receiver with respect to RF input level are shown in Figure 17. This information helps determine the network topology and gain blocks required ahead of the MC13150 to achieve the desired sensitivity and dynamic range of the receiver system. The PCB is laid out to accommodate a low noise preamp followed by the 83.16 MHz SAW filter. In the

application circuit (Figure 15), the input 1.0 dB compression point is  $-10$  dBm and the input third order intercept (IP3) performance of the system is approximately  $0$  dBm (see Figure 18).

## Typical Performance Over Temperature

# Wideband FM IF

The MC13155 is a complete wideband FM detector designed for satellite TV and other wideband data and analog FM applications. This device may be cascaded for higher IF gain and extended Receive Signal Strength Indicator (RSSI) range.

- 12 MHz Video/Baseband Demodulator
- Ideal for Wideband Data and Analog FM Systems
- Limiter Output for Cascade Operation
- Low Drain Current: 7.0 mA
- Low Supply Voltage: 3.0 to 6.0 V
- Operates to 300 MHz

## MAXIMUM RATINGS

Rating	Pin	Symbol	Value	Unit
Power Supply Voltage	11, 14	$V_{EE}$ (max)	6.5	Vdc
Input Voltage	1, 16	$V_{in}$	1.0	Vrms
Junction Temperature	–	$T_J$	+150	°C
Storage Temperature Range	–	$T_{stg}$	– 65 to +150	°C

**NOTE:** Devices should not be operated at or outside these values. The "Recommended Operating Conditions" provide for actual device operation.

# MC13155

## CIRCUIT DESCRIPTION

The MC13155 consists of a wideband three-stage limiting amplifier, a wideband quadrature detector which may be operated up to 200 MHz, and a received signal strength

indicator (RSSI) circuit which provides a current output linearly proportional to the IF input signal level for approximately 35 dB range of input level.

**Figure 2. Test Circuit**

## APPLICATIONS INFORMATION

### Evaluation PC Board

The evaluation PCB shown in Figures 19 and 20 is very versatile and is designed to cascade two ICs. The center section of the board provides an area for attaching all surface mount components to the circuit side and radial leaded components to the component ground side of the PCB (see Figures 17 and 18). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. This evaluation board will be discussed and referenced in this section.

### Limiting Amplifier

Differential input and output ports interfacing the three stage limiting amplifier provide a differential power gain of typically 46 dB and useable frequency range of 300 MHz. The IF gain flatness may be controlled by decoupling of the internal feedback network at Pins 2 and 15.

Scattering parameter (S-parameter) characterization of the IF as a two port linear amplifier is useful to implement maximum stable power gain, input matching, and stability over a desired bandpass response and to ensure stable operation outside the bandpass as well. The MC13155 is unconditionally stable over most of its useful operating frequency range; however, it can be made unconditionally stable over its entire operating range with the proper decoupling of Pins 2 and 15. Relatively small decoupling capacitors of about 100 pF have a significant effect on the wideband response and stability. This is shown in the scattering parameter tables where S-parameters are shown for various values of C2 and C15 and at VEE of -3.0 and -5.0 Vdc.

## MC13155

In the S-parameters measurements, the IF is treated as a two-port linear class A amplifier. The IF amplifier is measured with a single-ended input and output configuration in which the Pins 16 and 7 are terminated in the series combination of a 47 Ω resistor and a 10 nF capacitor to V<sub>CC</sub> ground (see Figure 14. S-Parameter Test Circuit).

The S-parameters are in polar form as the magnitude (MAG) and angle (ANG). Also listed in the tables are the calculated values for the stability factor (K) and the Maximum

Available Gain (MAG). These terms are related in the following equations:

$$K = (1 - |S_{11}|^2 - |S_{22}|^2 + |\Delta|^2) / (2 |S_{12} S_{21}|)$$

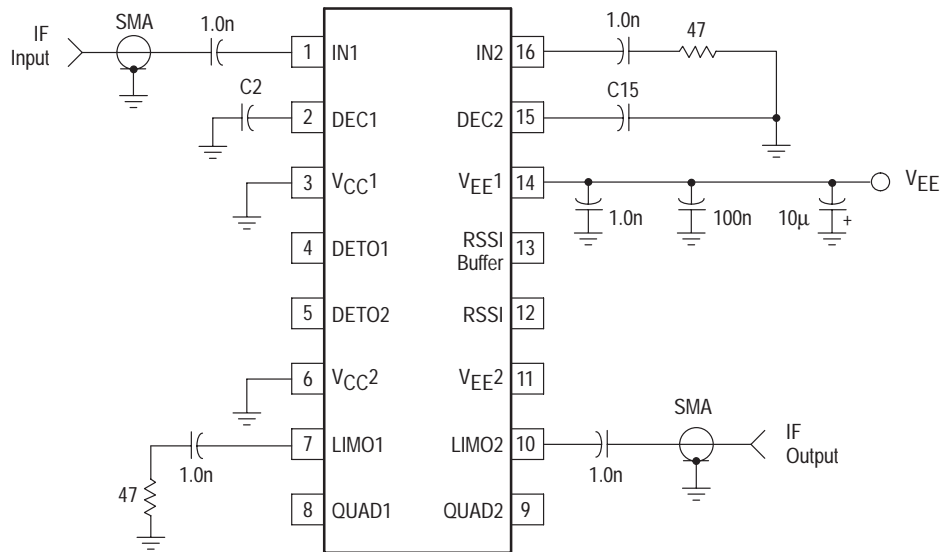

where:  $|\Delta| = |S_{11} S_{22} - S_{12} S_{21}|$ .

$$\text{MAG} = 10 \log |S_{21}| / |S_{12}| + 10 \log |K - (K^2 - 1)^{1/2}|$$

where:  $K > 1$ . The necessary and sufficient conditions for unconditional stability are given as  $K > 1$ :

$$B1 = 1 + |S_{11}|^2 - |S_{22}|^2 - |\Delta|^2 > 0$$

**DC Biasing Considerations**

The DC biasing scheme utilizes two  $V_{CC}$  connections (Pins 3 and 6) and two  $V_{EE}$  connections (Pins 14 and 11).  $V_{EE1}$  (Pin 14) is connected internally to the IF and RSSI circuits' negative supply bus while  $V_{EE2}$  (Pin 11) is connected internally to the quadrature detector's negative bus. Under positive ground operation, this unique configuration offers the ability to bias the RSSI and IF separately from the quadrature detector. When two ICs are cascaded as shown in the 70 MHz application circuit and provided by the PCB (see Figures 17 and 18), the first MC13155 is used without biasing its quadrature detector, thereby saving approximately 3.0 mA. A total current of 7.0 mA is used to fully bias each IC, thus the total current in the application circuit is approximately 11 mA. Both  $V_{CC}$  pins are biased by the same supply.  $V_{CC1}$  (Pin 3) is connected internally to the positive bus of the first half of the IF limiting amplifier, while  $V_{CC2}$  is internally connected to the positive bus of the RSSI, the quadrature detector circuit, and the second half of the IF limiting amplifier (see Figure 15). This distribution of the  $V_{CC}$  enhances the stability of the IC.

**RSSI Circuitry**

The RSSI circuitry provides typically 35 dB of linear dynamic range and its output voltage swing is adjusted by

selection of the resistor from Pin 12 to  $V_{EE}$ . The RSSI slope is typically  $2.1 \mu A/dB$ ; thus, for a dynamic range of 35 dB, the current output is approximately 74  $\mu A$ . A 47 k resistor will yield an RSSI output voltage swing of 3.5 Vdc. The RSSI buffer output at Pin 13 is an emitter-follower and needs an external emitter resistor of 10 k to  $V_{EE}$ .

In a cascaded configuration (see circuit application in Figure 16), only one of the RSSI Buffer outputs (Pin 13) is used; the RSSI outputs (Pin 12 of each IC) are tied together and the one closest to the  $V_{EE}$  supply trace is decoupled to  $V_{CC}$  ground. The two pins are connected to  $V_{EE}$  through a 47 k resistor. This resistor sources a RSSI current which is proportional to the signal level at the IF input; typically, 1.0 mVrms ( $-47$  dBm) is required to place the MC13155 into limiting. The measured RSSI output voltage response of the application circuit is shown in Figure 12. Since the RSSI current output is dependent upon the input signal level at the IF input, a careful accounting of filter losses, matching and other losses and gains must be made in the entire receiver system. In the block diagram of the application circuit shown below, an accounting of the signal levels at points throughout the system shows how the RSSI response in Figure 12 is justified.

**Block Diagram of 70 MHz Video Receiver Application Circuit**

**Cascading Stages**

The limiting IF output is pinned-out differentially, cascading is easily achieved by AC coupling stage to stage. In the evaluation PCB, AC coupling is shown, however, interstage filtering may be desirable in some applications. In which case, the S-parameters provide a means to implement a low loss interstage match and better receiver sensitivity.

Where a linear response of the RSSI output is desired when cascading the ICs, it is necessary to provide at least 10 dB of interstage loss. Figure 12 shows the RSSI response with and without interstage loss. A 15 dB resistive attenuator is an inexpensive way to linearize the RSSI response. This has its drawbacks since it is a wideband noise source that is dependent upon the source and load impedance and the amount of attenuation that it provides. A better, although more costly, solution would be a bandpass filter designed to the desired center frequency and bandpass response while carefully selecting the insertion loss. A network topology

shown below may be used to provide a bandpass response with the desired insertion loss.

**Network Topology**

### Quadrature Detector

The quadrature detector is coupled to the IF with internal 2.0 pF capacitors between Pins 7 and 8 and Pins 9 and 10. For wideband data applications, such as FM video and satellite receivers, the drive to the detector can be increased with additional external capacitors between these pins, thus, the recovered video signal level output is increased for a given bandwidth (see Figure 11A and Figure 11B).

The wideband performance of the detector is controlled by the loaded Q of the LC tank circuit. The following equation defines the components which set the detector circuit's bandwidth:

$$Q = R_T / X_L \quad (1)$$

where:  $R_T$  is the equivalent shunt resistance across the LC Tank and  $X_L$  is the reactance of the quadrature inductor at the IF frequency ( $X_L = 2\pi fL$ ).

The inductor and capacitor are chosen to form a resonant LC Tank with the PCB and parasitic device capacitance at the desired IF center frequency as predicted by:

$$f_c = (2\pi \sqrt{LC_p})^{-1} \quad (2)$$

where: L is the parallel tank inductor and  $C_p$  is the equivalent parallel capacitance of the parallel resonant tank circuit.

The following is a design example for a wideband detector at 70 MHz and a loaded Q of 5. The loaded Q of the quadrature detector is chosen somewhat less than the Q of the IF bandpass. For an IF frequency of 70 MHz and an IF bandpass of 10.9 MHz, the IF bandpass Q is approximately 6.4.

Example:

Let the external  $C_{ext} = 20$  pF. (The minimum value here should be greater than 15 pF making it greater than the internal device and PCB parasitic capacitance,  $C_{int} \approx 3.0$  pF).

$$C_p = C_{int} + C_{ext} = 23 \text{ pF}$$

Rewrite Equation 2 and solve for L:

$$L = (0.159)^2 / (C_p f_c^2)$$

$$L = 198 \text{ nH, thus, a standard value is chosen.}$$

$$L = 0.22 \text{ } \mu\text{H (tunable shielded inductor).}$$

The value of the total damping resistor to obtain the required loaded Q of 5 can be calculated by rearranging Equation 1:

$$R_T = Q(2\pi fL)$$

$$R_T = 5 (2\pi)(70)(0.22) = 483.8 \text{ } \Omega.$$

The internal resistance,  $R_{int}$  between the quadrature tank Pins 8 and 9 is approximately 3200  $\Omega$  and is considered in determining the external resistance,  $R_{ext}$  which is calculated from:

$$R_{ext} = ((R_T)(R_{int})) / (R_{int} - R_T)$$

$$R_{ext} = 570, \text{ thus, choose the standard value.}$$

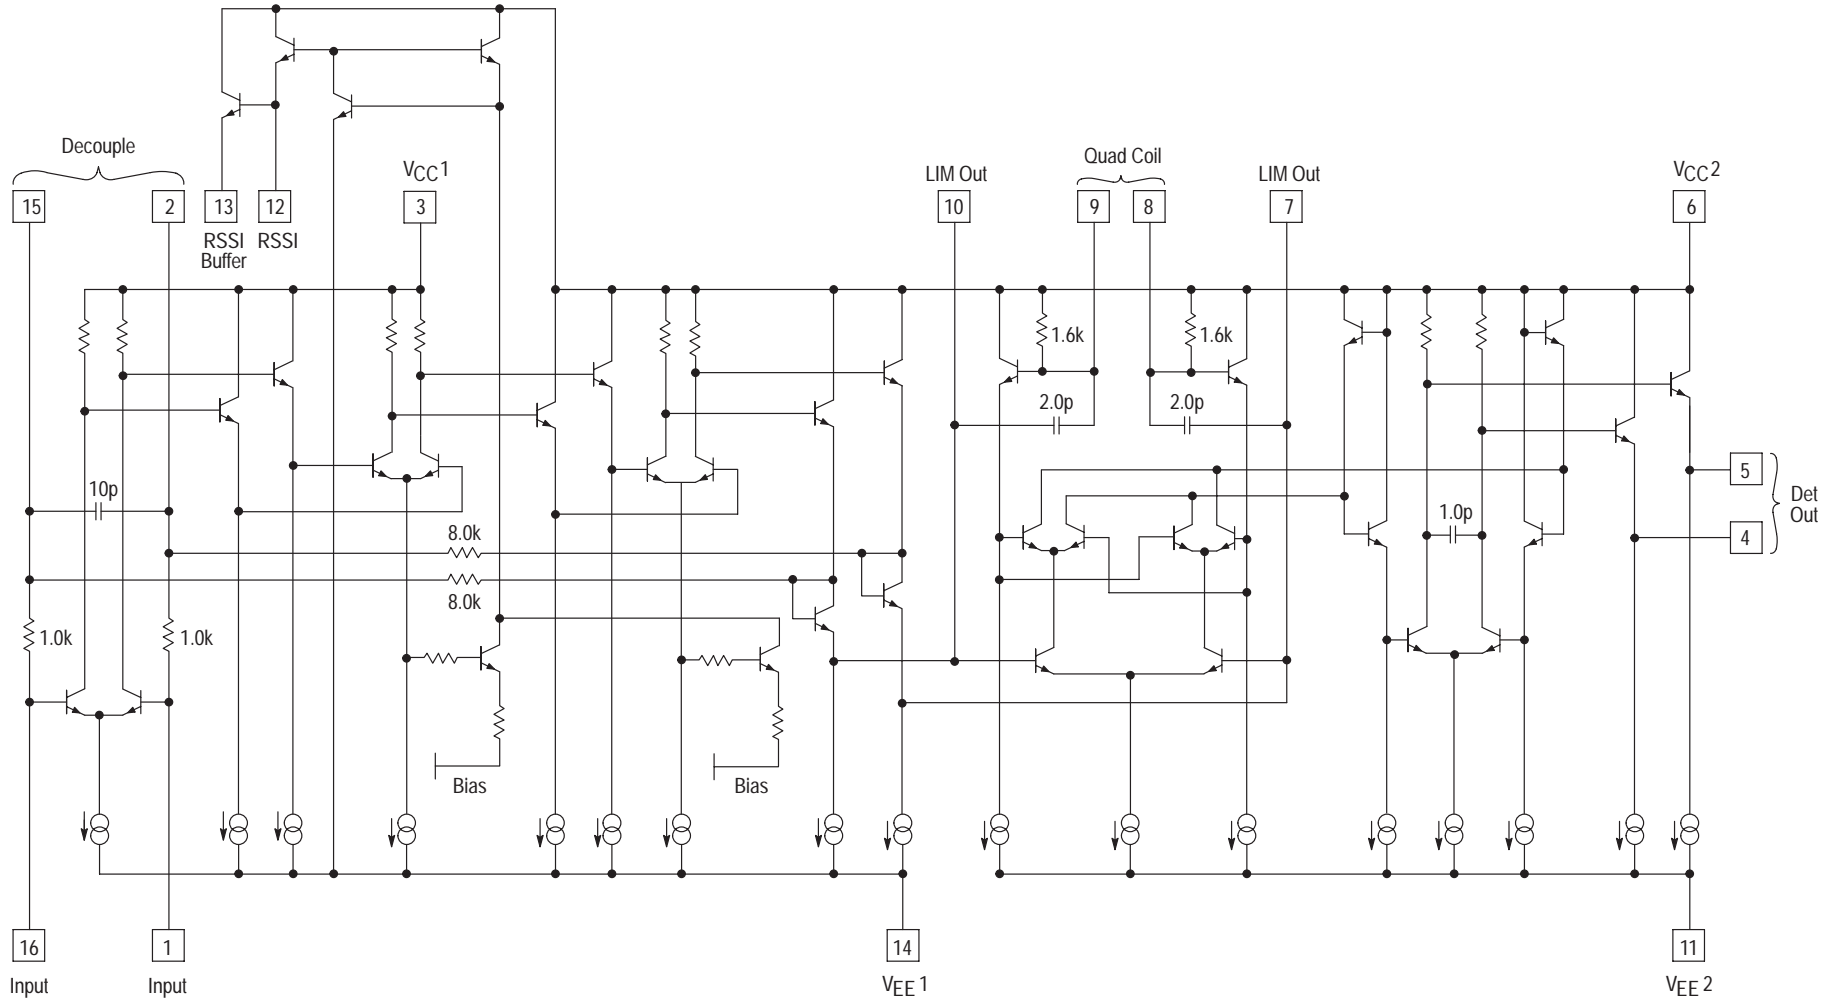

$$R_{ext} = 560 \text{ } \Omega.$$

### SAW Filter

In wideband video data applications, the IF occupied bandwidth may be several MHz wide. A good rule of thumb is to choose the IF frequency about 10 or more times greater than the IF occupied bandwidth. The IF bandpass filter is a SAW filter in video data applications where a very selective response is needed (i.e., very sharp bandpass response). The evaluation PCB is laid out to accommodate two SAW filter package types: 1) A five-leaded plastic SIP package. Recommended part numbers are Siemens X6950M which operates at 70 MHz; 10.4 MHz 3 dB passband, X6951M (X252.8) which operates at 70 MHz; 9.2 MHz 3 dB passband; and X6958M which operates at 70 MHz, 6.3 MHz 3 dB passband, and 2) A four-leaded TO-39 metal can package. Typical insertion loss in a wide bandpass SAW filter is 25 dB.

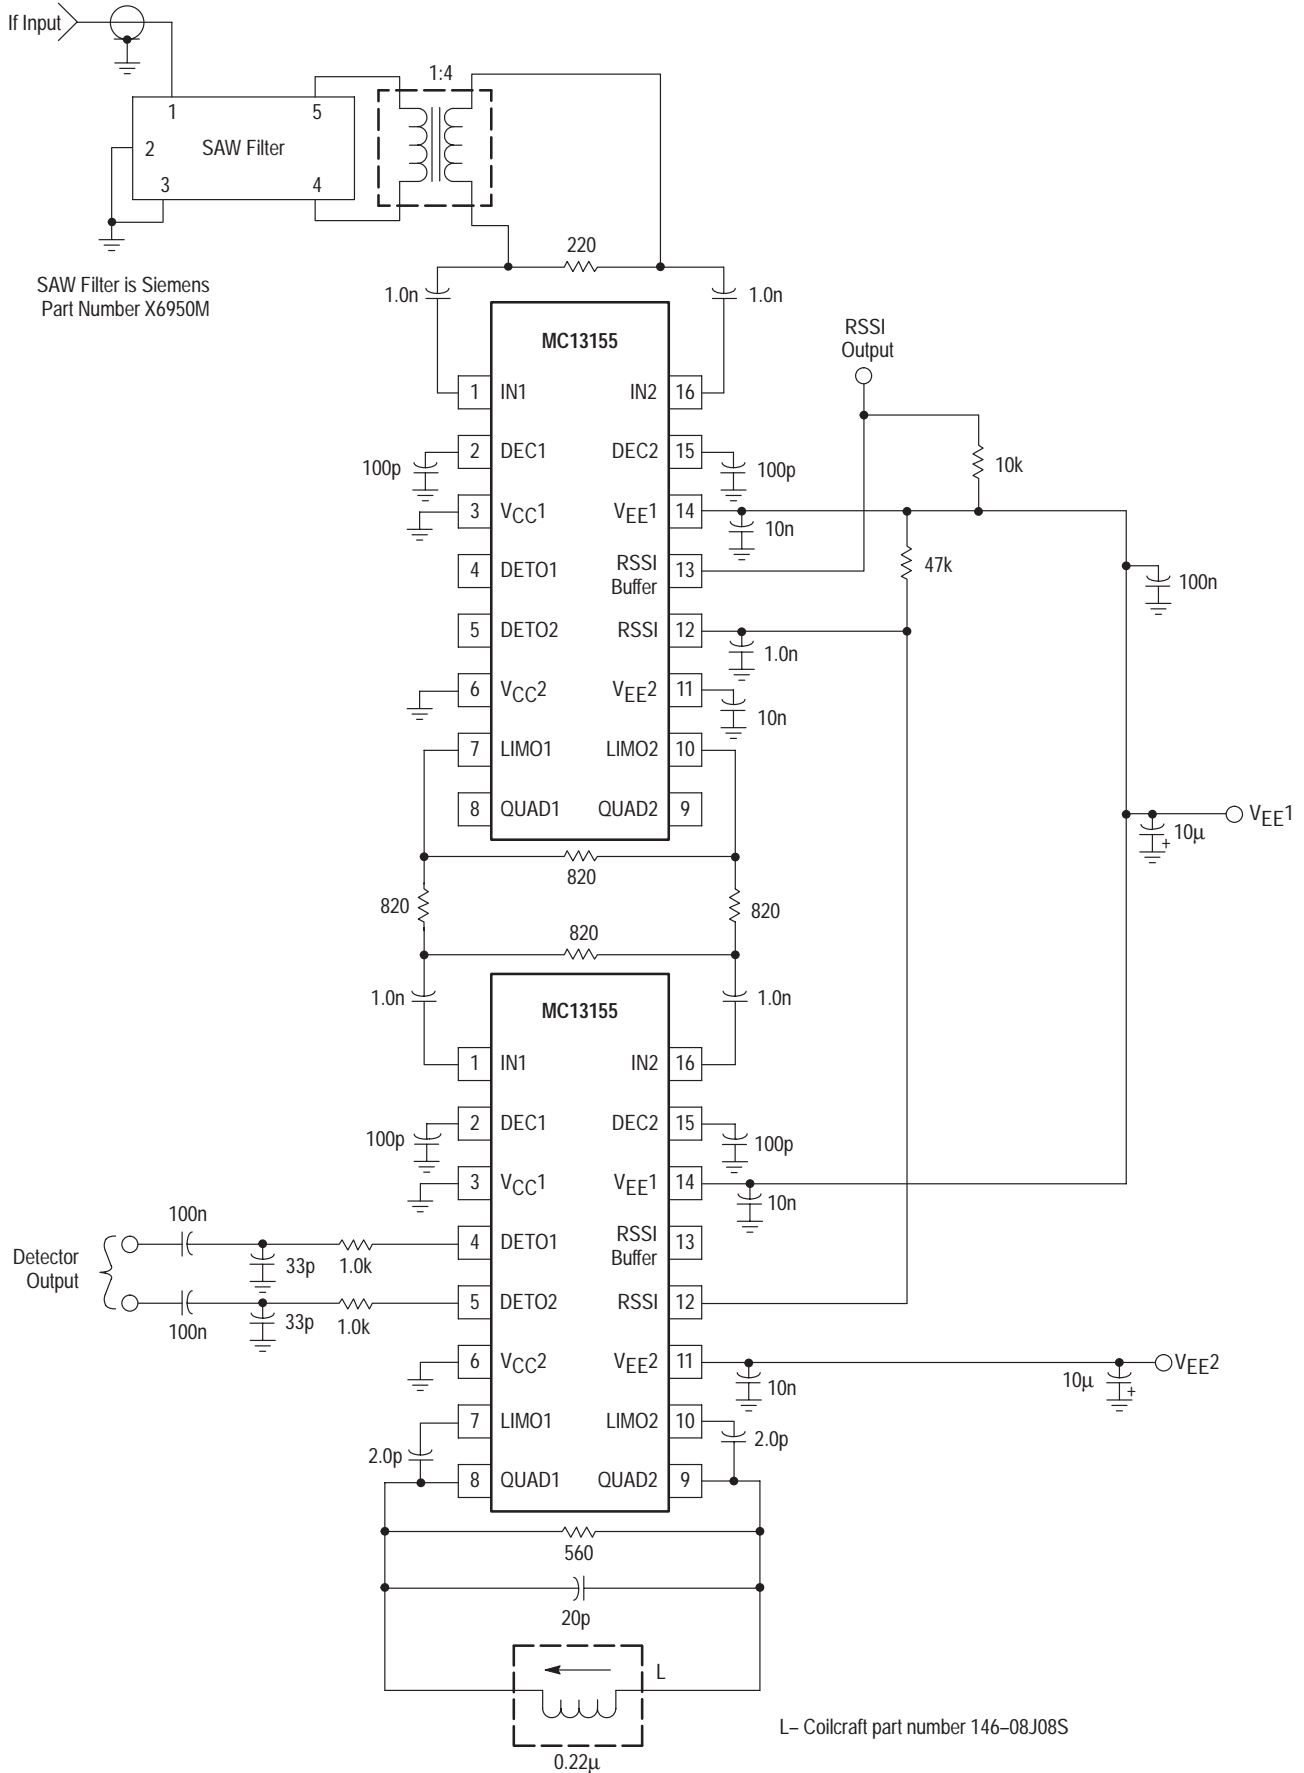

The above SAW filters require source and load impedances of 50  $\Omega$  to assure stable operation. On the PC board layout, space is provided to add a matching network, such as a 1:4 surface mount transformer between the SAW filter output and the input to the MC13155. A 1:4 transformer, made by Coilcraft and Mini Circuits, provides a suitable interface (see Figures 16, 17 and 18). In the circuit and layout, the SAW filter and the MC13155 are differentially configured with interconnect traces which are equal in length and symmetrical. This balanced feed enhances RF stability, phase linearity, and noise performance.

## Wideband FM IF System

The MC13156 is a wideband FM IF subsystem targeted at high performance data and analog applications. Excellent high frequency performance is achieved at low cost using Motorola's MOSAIC 1.5™ bipolar process. The MC13156 has an onboard grounded collector VCO transistor that may be used with a fundamental or overtone crystal in single channel operation or with a PLL in multichannel operation. The mixer is useful to 500 MHz and may be used in a balanced-differential, or single-ended configuration. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. A precision data shaper has a hold function to preset the shaper for fast recovery of new data.

Applications for the MC13156 include CT-2, wideband data links and other radio systems utilizing GMSK, FSK or FM modulation.

- 2.0 to 6.0 Vdc Operation
- Typical Sensitivity at 200 MHz of 2.0  $\mu$ V for 12 dB SINAD
- RSSI Dynamic Range Typically 80 dB
- High Performance Data Shaper for Enhanced CT-2 Operation
- Internal 330  $\Omega$  and 1.4 k $\Omega$  Terminations for 10.7 MHz and 455 kHz Filters
- Split IF for Improved Filtering and Extended RSSI Range
- 3rd Order Intercept (Input) of -25 dBm (Input Matched)

## CIRCUIT DESCRIPTION

### General

The MC13156 is a low power single conversion wideband FM receiver incorporating a split IF. This device is designated for use as the backend in digital FM systems such as CT-2 and wideband data links with data rates up to 500 kbaud. It contains a mixer, oscillator, signal strength meter drive, IF amplifier, limiting IF, quadrature detector and a data slicer with a hold function (refer to Figure 8, Simplified Internal Circuit Schematic).

### Current Regulation

Temperature compensating voltage independent current regulators are used throughout.

### Mixer

The mixer is a double-balanced four quadrant multiplier and is designed to work up to 500 MHz. It can be used in differential or in single-ended mode by connecting the other input to the positive supply rail.

Figure 4 shows the mixer gain and saturated output response as a function of input signal drive. The circuit used to measure this is shown in Figure 1. The linear gain of the mixer is approximately 22 dB. Figure 9 shows the mixer gain versus the IF output frequency with the local oscillator of 150 MHz at 100 mVrms LO drive level. The RF frequency is swept. The sensitivity of the IF output of the mixer is shown in Figure 10 for an RF input drive of 10 mVrms at 140 MHz and IF at 10 MHz.

The single-ended parallel equivalent input impedance of the mixer is  $R_p \sim 1.0 \text{ k}\Omega$  and  $C_p \sim 4.0 \text{ pF}$  (see Table 1 for details). The buffered output of the mixer is internally loaded resulting in an output impedance of  $330 \Omega$ .

### Local Oscillator

The on-chip transistor operates with crystal and LC resonant elements up to 220 MHz. Series resonant, overtone crystals are used to achieve excellent local oscillator stability. 3rd overtone crystals are used through about 65 to 70 MHz. Operation from 70 MHz up to 180 MHz is feasible using the on-chip transistor with a 5th or 7th overtone crystal. To enhance operation using an overtone crystal, the internal transistor's bias is increased by adding an external resistor from Pin 23 to  $V_{EE}$ .  $-10 \text{ dBm}$  of local oscillator drive is needed to adequately drive the mixer (Figure 10).

The oscillator configurations specified above, and two others using an external transistor, are described in the application section:

- 1) A 133 MHz oscillator multiplier using a 3rd overtone crystal, and
- 2) A 307.8 to 309.3 MHz manually tuned, varactor controlled local oscillator.

### RSSI

The Received Signal Strength Indicator (RSSI) output is a current proportional to the log of the received signal

amplitude. The RSSI current output is derived by summing the currents from the IF and limiting amplifier stages. An external resistor at Pin 20 sets the voltage range or swing of the RSSI output voltage. Linearity of the RSSI is optimized by using external ceramic or crystal bandpass filters which have an insertion loss of 8.0 dB. The RSSI circuit is designed to provide 70+ dB of dynamic range with temperature compensation (see Figures 6 and 7 which show RSSI responses of the IF and Limiter amplifiers). Variation in the RSSI output current with supply voltage is small (see Figure 11).

### Carrier Detect

When the meter current flowing through the meter load resistance reaches 1.2 Vdc above ground, the comparator flips, causing the carrier detect output to go high. Hysteresis can be accomplished by adding a very large resistor for positive feedback between the output and the input of the comparator.

### IF Amplifier

The first IF amplifier section is composed of three differential stages with the second and third stages contributing to the RSSI. This section has internal dc feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 39 dB at 10.7 MHz. Figure 5 shows the gain and saturated output response of the IF amplifier over temperature, while Figure 12 shows the IF amplifier gain as a function of the IF frequency.

The fixed internal input impedance is  $1.4 \text{ k}\Omega$ . It is designed for applications where a 455 kHz ceramic filter is used and no external output matching is necessary since the filter requires a  $1.4 \text{ k}\Omega$  source and load impedance.

For 10.7 MHz ceramic filter applications, an external  $430 \Omega$  resistor must be added in parallel to provide the equivalent load impedance of  $330 \Omega$  that is required by the filter; however, no external matching is necessary at the input since the mixer output matches the  $330 \Omega$  source impedance of the filter. For 455 kHz applications, an external  $1.1 \text{ k}\Omega$  resistor must be added in series with the mixer output to obtain the required matching impedance of  $1.4 \text{ k}\Omega$  of the filter input resistance. Overall RSSI linearity is dependent on having total midband attenuation of 12 dB (6.0 dB insertion loss plus 6.0 dB impedance matching loss) for the filter. The output of the IF amplifier is buffered and the impedance is  $290 \Omega$ .

### Limiter

The limiter section is similar to the IF amplifier section except that four stages are used with the last three contributing to the RSSI. The fixed internal input impedance is  $1.4 \text{ k}\Omega$ . The total gain of the limiting amplifier section is approximately 55 dB. This IF limiting amplifier section internally drives the quadrature detector section.

Figure 11. RSSI Output Current versus Supply Voltage and RF Input Signal Level

Figure 12. IF Amplifier Gain versus IF Frequency

Figure 13. Recovered Audio Output Voltage versus Supply Voltage

### Quadrature Detector

The quadrature detector is a doubly balanced four quadrant multiplier with an internal 5.0 pF quadrature capacitor to couple the IF signal to the external parallel RLC resonant circuit that provides the 90 degree phase shift and drives the quadrature detector. A single pin (Pin 13) provides for the external LC parallel resonant network and the internal connection to the quadrature detector.

The bandwidth of the detector allows for recovery of relatively high data rate modulation. The recovered signal is converted from differential to single ended through a push-pull NPN/PNP output stage. Variation in recovered audio output voltage with supply voltage is very small (see Figure 13). The output drive capability is approximately  $\pm 9.0 \mu\text{A}$  for a frequency deviation of  $\pm 75 \text{ kHz}$  and 1.0 kHz modulating frequency (see Application Circuit).

### Data Slicer

The data slicer input (Pin 15) is self centering around 1.1 V with clamping occurring at  $1.1 \pm 0.5 V_{\text{BE}}$  Vdc. It is designed to square up the data signal. Figure 14 shows a detailed schematic of the data slicer.

The Voltage Regulator sets up 1.1 Vdc on the base of Q12, the Differential Input Amplifier. There is a potential of  $1.0 V_{\text{BE}}$  on the base-collector of transistor diode Q11 and  $2.0 V_{\text{BE}}$  on the base-collector of Q10. This sets up a  $1.5 V_{\text{BE}}$  ( $\sim 1.1 \text{ Vdc}$ ) on the node between the 36 k $\Omega$  resistors which is connected to the base of Q12. The differential output of the data slicer Q12 and Q13 is converted to a single-ended output by the Driver Circuit. Additional circuitry, not shown in Figure 14, tends to keep the data slicer input centered at 1.1 Vdc as input signal levels vary.

The Input Diode Clamp Circuit provides the clamping at  $1.0 V_{\text{BE}}$  (0.75 Vdc) and  $2.0 V_{\text{BE}}$  (1.45 Vdc). Transistor diodes Q7 and Q8 are on, thus, providing a  $2.0 V_{\text{BE}}$  potential at the base of Q1. Also, the voltage regulator circuit provides a potential of  $2.0 V_{\text{BE}}$  on the base of Q3 and  $1.0 V_{\text{BE}}$  on the emitter of Q3 and Q2. When the data slicer input (Pin 15) is

pulled up, Q1 turns off; Q2 turns on, thereby clamping the input at  $2.0 V_{\text{BE}}$ . On the other hand, when Pin 15 is pulled down, Q1 turns on; Q2 turns off, thereby clamping the input at  $1.0 V_{\text{BE}}$ .

The recovered data signal from the quadrature detector is ac coupled to the data slicer via an input coupling capacitor. The size of this capacitor and the nature of the data signal determine how faithfully the data slicer shapes up the recovered signal. The time constant is short for large peak to peak voltage swings or when there is a change in dc level at the detector output. For small signal or for continuous bits of the same polarity which drift close to the threshold voltage, the time constant is longer. When centered there is no input current allowed, which is to say, that the input looks high in impedance.

Another unique feature of the data slicer is that it responds to various logic levels applied to the Data Slicer Hold Control pin (Pin 18). Figure 15 illustrates how the input and output currents under "no hold" condition relate to the input voltage. Figure 16 shows how the input current and input voltage relate for both the "no hold" and "hold" condition.

The hold control (Pin18) does three separate tasks:

- 1) With Pin 18 at  $1.0 V_{\text{BE}}$  or greater, the output is shut off (sets high). Q19 turns on which shunts the base drive from Q20, thereby turning the output off.
- 2) With Pin 18 at  $2.0 V_{\text{BE}}$  or greater, internal clamping diodes are open circuited and the comparator input is shut off and effectively open circuited. This is accomplished by turning off the current source to emitters of the input differential amplifier, thus, the input differential amplifier is shut off.
- 3) When the input is shut off, it allows the input capacitor to hold its charge during transmit to improve recovery at the beginning of the next receive period. When it is turned on, it allows for very fast charging of the input capacitor for quick recovery of new tuning or data average. The above features are very desirable in a TDD digital FM system.

### Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers and coil types. Figures 18 and 19 show the placement for the components specified in the application circuit (Figure 17). The applications circuit schematic specifies particular components that were used to achieve the results shown in the typical curves and tables but equivalent components should give similar results.

### Input Matching Networks/Components

The input matching circuit shown in the application circuit schematic is passive high pass network which offers effective image rejection when the local oscillator is below the RF input frequency. Silver mica capacitors are used for their high Q and tight tolerance. The PC board is not dedicated to any particular input matching network topology; space is provided for the designer to breadboard as desired.

Alternate matching networks using 4:1 surface mount transformers or BALUNs provide satisfactory performance. The 12 dB SINAD sensitivity using the above matching networks is typically  $-100$  dBm for  $f_{\text{mod}} = 1.0$  kHz and  $f_{\text{dev}} = \pm 75$  kHz at  $f_{\text{IN}} = 144.45$  MHz and  $f_{\text{OSC}} = 133.75$  MHz (see Figure 25).

It is desirable to use a SAW filter before the mixer to provide additional selectivity and adjacent channel rejection and improved sensitivity. The SAW filter should be designed to interface with the mixer input impedance of approximately 1.0 k $\Omega$ . Table 1 displays the series equivalent single-ended mixer input impedance.

### Local Oscillators

**VHF Applications** – The local oscillator circuit shown in the application schematic utilizes a third overtone crystal and an RF transistor. Selecting a transistor having good phase noise performance is important; a mandatory criteria is for the

device to have good linearity of beta over several decades of collector current. In other words, if the low current beta is suppressed, it will not offer good 1/f noise performance. A third overtone series resonant crystal having at least 25 ppm tolerance over the operating temperature is recommended. The local oscillator is an impedance inversion third overtone Colpitts network and harmonic generator. In this circuit a 560 to 1.0 k $\Omega$  resistor shunts the crystal to ensure that it operates in its overtone mode; thus, a blocking capacitor is needed to eliminate the dc path to ground. The resulting parallel LC network should “free-run” near the crystal frequency if a short to ground is placed across the crystal. To provide sufficient output loading at the collector, a high Q variable inductor is used that is tuned to self resonate at the 3rd harmonic of the overtone crystal frequency.

The on-chip grounded collector transistor may be used for HF and VHF local oscillator with higher order overtone crystals. Figure 20 shows a 5th overtone oscillator at 93.3 MHz and Figure 21 shows a 7th overtone oscillator at 148.3 MHz. Both circuits use a Butler overtone oscillator configuration. The amplifier is an emitter follower. The crystal is driven from the emitter and is coupled to the high impedance base through a capacitive tap network. Operation at the desired overtone frequency is ensured by the parallel resonant circuit formed by the variable inductor and the tap capacitors and parasitic capacitances of the on-chip transistor and PC board. The variable inductor specified in the schematic could be replaced with a high tolerance, high Q ceramic or air wound surface mount component if the other components have good tolerances. A variable inductor provides an adjustment for gain and frequency of the resonant tank ensuring lock up and startup of the crystal oscillator. The overtone crystal is chosen with ESR of typically 80  $\Omega$  and 120  $\Omega$  maximum; if the resistive loss in the crystal is too high, the performance of the oscillator may be impacted by lower gain margins.

**Table 1. Mixer Input Impedance Data**

(Single-ended configuration,  $V_{\text{CC}} = 3.0$  Vdc, local oscillator drive = 100 mVrms)

Frequency (MHz)	Series Equivalent Complex Impedance (R + jX) ( $\Omega$ )	Parallel Resistance $R_p$ ( $\Omega$ )	Parallel Capacitance $C_p$ (pF)
90	190 – j380	950	4.7
100	160 – j360	970	4.4
110	130 – j340	1020	4.2
120	110 – j320	1040	4.2

## MC13156

A series LC network to ground (which is  $V_{CC}$ ) is comprised of the inductance of the base lead of the on-chip transistor and PC board traces and tap capacitors. Parasitic oscillations often occur in the 200 to 800 MHz range. A small resistor is placed in series with the base (Pin 24) to cancel the negative resistance associated with this undesired mode of oscillation. Since the base input impedance is so large a small resistor in the range of 27 to 68  $\Omega$  has very little effect on the desired Butler mode of oscillation.

The crystal parallel capacitance,  $C_O$ , provides a feedback path that is low enough in reactance at frequencies of 5th overtone or higher to cause trouble.  $C_O$  has little effect near resonance because of the low impedance of the crystal motional arm ( $R_m-L_m-C_m$ ). As the tunable inductor which forms the resonant tank with the tap capacitors is tuned off the crystal resonant frequency, it may be difficult to tell if the oscillation is under crystal control. Frequency jumps may occur as the inductor is tuned. In order to eliminate this behavior an inductor ( $L_O$ ) is placed in parallel with the crystal.  $L_O$  is chosen to resonant with the crystal parallel capacitance ( $C_O$ ) at the desired operation frequency. The inductor provides a feedback path at frequencies well below resonance; however, the parallel tank network of the tap capacitors and tunable inductor prevent oscillation at these frequencies.

### UHF Application

Figure 22 shows a 318.5 to 320 MHz receiver which drives the mixer with an external varactor controlled (307.8 to 309.3 MHz) LC oscillator using an MPS901 (RF low power transistor in a TO-92 plastic package; also MMBR901 is available in a SOT-23 surface mount package). With the 50 k $\Omega$  10 turn potentiometer this oscillator is tunable over a range of approximately 1.5 MHz. The MMBV909L is a low

voltage varactor suitable for UHF applications; it is a dual back-to-back varactor in a SOT-23 package. The input matching network uses a 1:4 impedance matching transformer (Recommended sources are Mini-Circuits and Coilcraft).

Using the same IF ceramic filters and quadrature detector circuit as specified in the applications circuit in Figure 17, the 12 dB SINAD performance is -95 dBm for a  $f_{mod} = 1.0$  kHz sinusoidal waveform and  $f_{dev} \pm 40$  kHz.

This circuit is breadboarded using the evaluation PC board shown in Figures 32 and 33. The RF ground is  $V_{CC}$  and path lengths are minimized. High quality surface mount components were used except where specified. The absolute values of the components used will vary with layout placement and component parasitics.

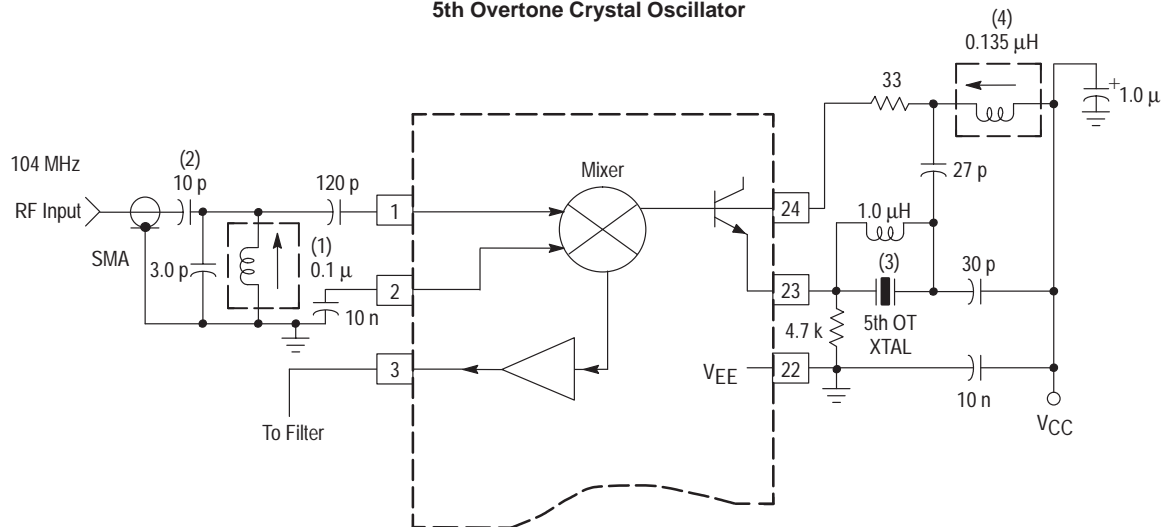

### RSSI Response

Figure 26 shows the full RSSI response in the application circuit. The 10.7 MHz, 110 kHz wide bandpass ceramic filters (recommended sources are TOKO part # SK107M5-AO-10X or Murata Erie SFE10.7MHY-A) provide the correct bandpass insertion loss to linearize the curve between the limiter and IF portions of RSSI. Figure 25 shows that limiting occurs at an input of -100 dBm. As shown in Figure 26, the RSSI output linear from -100 dBm to -30 dBm.

The RSSI rise and fall times for various RF input signal levels and R20 values are measured at Pin 20 without 10 nF filter capacitor. A 10 kHz square wave pulses the RF input signal on and off. Figure 27 shows that the rise and fall times are short enough to recover greater than 10 kHz ASK data; with a wider IF bandpass filters data rates up to 50 kHz may be achieved. The circuit used is the application circuit in Figure 17 with no RSSI output filter capacitor.

## 45 MHz Narrowband Receiver

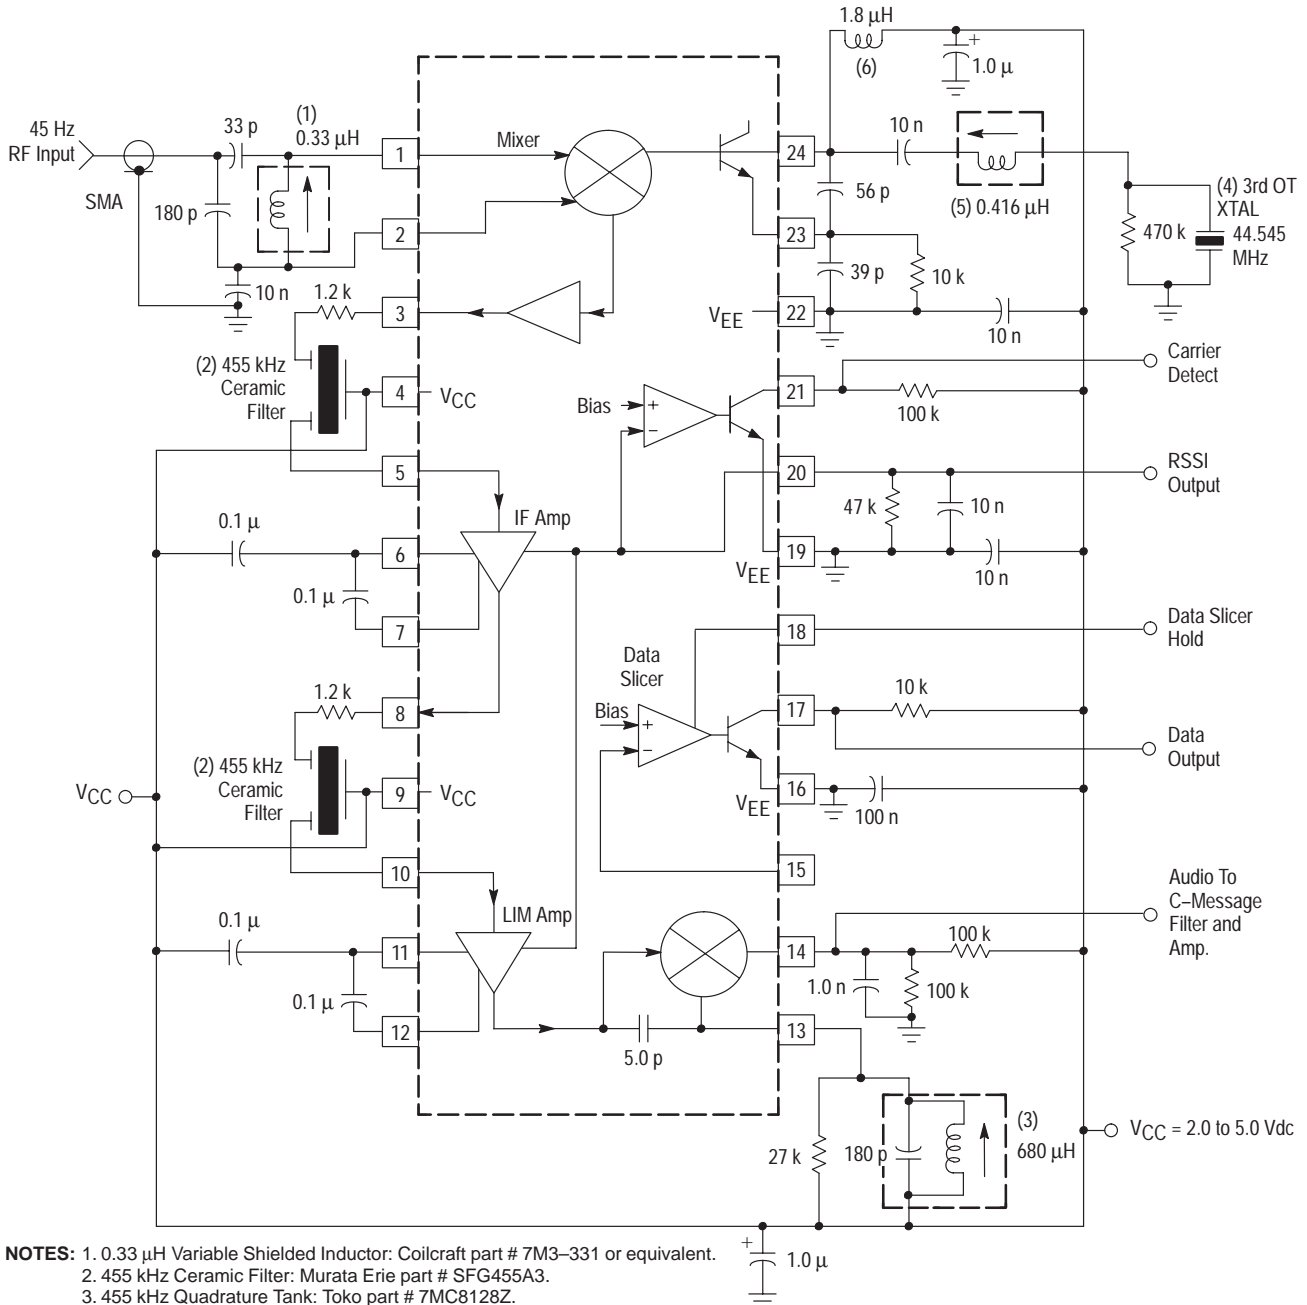

The above application examples utilize a 10.7 MHz IF. In this section a narrowband receiver with a 455 kHz IF will be described. Figure 23 shows a full schematic of a 45 MHz receiver that uses a 3rd overtone crystal with the on-chip oscillator transistor. The oscillator configuration is similar to the one used in Figure 17; it is called an impedance inversion Colpitts. A 44.545 MHz 3rd overtone, series resonant crystal is used to achieve an IF frequency at 455 kHz. The ceramic IF filters selected are Murata Erie part # SFG455A3. 1.2 k $\Omega$  chip resistors are used in series with the filters to achieve the terminating resistance of 1.4 k $\Omega$  to the filter. The IF decoupling is very important; 0.1  $\mu$ F chip capacitors are used at Pins 6, 7, 11 and 12. The quadrature detector tank circuit uses a 455 kHz quadrature tank from Toko.

The 12 dB SINAD performance is  $-109$  dBm for a  $f_{mod} = 1.0$  kHz and a  $f_{dev} = \pm 4.0$  kHz. The RSSI dynamic range is approximately 80 dB of linear range (see Figure 24).

## Receiver Design Considerations

The curves of signal levels at various portions of the application receiver with respect to RF input level are shown in Figure 28. This information helps determine the network topology and gain blocks required ahead of the MC13156 to achieve the desired sensitivity and dynamic range of the receiver system. In the application circuit the input third order intercept (IP3) performance of the system is approximately  $-25$  dBm (see Figure 29).

## BER TESTING AND PERFORMANCE

### Description

The test setup shown in Figure 31 is configured so that the function generator supplies a 100 kHz clock source to the bit error rate tester. This device generates and receives a repeating data pattern and drives a 5 pole baseband data filter. The filter effectively reduces harmonic content of the baseband data which is used to modulate the RF generator which is running at 144.45 MHz. Following processing of the signal by the receiver (MC13156), the recovered baseband sinewave (data) is AC coupled to the data slicer. The data slicer is essentially an auto-threshold comparator which tracks the zero crossing of the incoming sinewave and provides logic level data at its output. Data errors associated with the recovered data are collected by the bit error rate receiver and displayed.

Bit error rate versus RF signal input level and IF filter bandwidth are shown in Figure 30. The bit error rate data was taken under the following test conditions:

- Data rate = 100 kbps
- Filter cutoff frequency set to 39% of the data rate or 39 kHz.
- Filter type is a 5 pole equal-ripple with  $0.5^\circ$  phase error.
- $V_{CC} = 4.0$  Vdc
- Frequency deviation =  $\pm 32$  kHz.

**Figure 30. Bit Error Rate versus RF Input Signal Level and IF Bandpass Filter**

### Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side (see Figures 32 and 33). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates.

## Wideband FM IF Subsystem

The MC13158 is a wideband IF subsystem that is designed for high performance data and analog applications. Excellent high frequency performance is achieved, with low cost, through the use of Motorola's MOSAIC 1.5™ RF bipolar process. The MC13158 has an on-board grounded collector VCO transistor that may be used with a fundamental or overtone crystal in single channel operation or with a PLL in multi-channel operation. The mixer is useful to 500 MHz and may be used in a balanced differential or single ended configuration. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. A precision data shaper has an Off function to shut the output off to save current. An enable control is provided to power down the IC for power management in battery operated applications.

Applications include DECT, wideband wireless data links for personal and portable laptop computers and other battery operated radio systems which utilize GFSK, FSK or FM modulation.

- Designed for DECT Applications
- 1.8 to 6.0 Vdc Operating Voltage
- Low Power Consumption in Active and Standby Mode
- Greater than 600 kHz Detector Bandwidth
- Data Slicer with Special Off Function
- Enable Function for Power Down of Battery Operated Systems
- RSSI Dynamic Range of 80 dB Minimum
- Low External Component Count

## CIRCUIT DESCRIPTION

### General

The MC13158 is a low power single conversion wideband FM receiver incorporating a split IF. This device is designated for use as the backend in digital FM systems such as Digital European Cordless Telephone (DECT) and wideband data links with data rates up to 2.0 Mbps. It contains a mixer, oscillator, Received Signal Strength Indicator (RSSI), IF amplifier, limiting IF, quadrature detector, power down or enable function, and a data slicer with output off function. Further details are covered in the Pin Function Description which shows the equivalent internal circuit and external circuit requirements.

### Current Regulation/Enable

Temperature compensating voltage independent current regulators which are controlled by the enable pin (Pin 25) where “low” powers up and “high” powers down the entire circuit.

### Mixer

The mixer is a double-balanced four quadrant multiplier and is designed to work up to 500 MHz. It can be used in differential or in single ended mode by connecting the other input to the positive supply rail. The linear gain of the mixer is approximately 22 dB at 100 mVrms LO drive level. The mixer gain and noise figure have been emphasized at the expense of intermodulation performance. RSSI measurements are added in the mixer to extend the range to higher signal levels. The single-ended parallel equivalent input impedance of the mixer is  $R_p \sim 1.0 \text{ k}\Omega$  and  $C_p \sim 2.0 \text{ pF}$ . The buffered output of the mixer is internally loaded resulting in an output impedance of 330  $\Omega$ .

### Local Oscillator

The on-chip transistor operates with crystal and LC resonant elements up to 220 MHz. Series resonant, overtone crystals are used to achieve excellent local oscillator stability. Third overtone crystals are used through about 65 to 70 MHz. Operation from 70 MHz up to 180 MHz is feasible using the on-chip transistor with a 5th or 7th overtone crystal. To enhance operation using an overtone crystal, the internal transistor bias is increased by adding an external resistor from Pin 29 to  $V_{EE}$ ; however, with an external resistor the oscillator stays on during power down. Typically,  $-10 \text{ dBm}$  of local oscillator drive is needed to adequately drive the mixer. With an external oscillator source, the IC can be operated up to 500 MHz.

### RSSI

The received signal strength indicator (RSSI) output is a current proportional to the log of the received signal amplitude. The RSSI current output is derived by summing the currents from the mixer, IF and limiting amplifier stages. An increase in RSSI dynamic range, particularly at higher input signal levels is achieved. The RSSI circuit is designed to provide typically 85 dB of dynamic range with temperature compensation.

Linearity of the RSSI is optimized by using external ceramic bandpass filters which have an insertion loss of 4.0 dB and 330  $\Omega$  source and load impedance. For higher data rates used in DECT and related applications, LC bandpass filtering is necessary to acquire the desired

bandpass response; however, the RSSI linearity will require the same insertion loss.

### RSSI Buffer

The RSSI output current creates a voltage across an external resistor. A unity voltage-gain amplifier is used to buffer this voltage. The output of this buffer has an active pull-up but no pull-down, so it can also be used as a peak detector. The negative slew rate is determined by external capacitance and resistance to the negative supply.

### IF Amplifier

The first IF amplifier section is composed of three differential stages with the second and third stages contributing to the RSSI. This section has internal DC feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 40 dB at 10.7 MHz.

The fixed internal input impedance is 330  $\Omega$ . When using ceramic filters requiring source and load impedances of 330  $\Omega$ , no external matching is necessary. Overall RSSI linearity is dependent on having total midband attenuation of 10 dB (4.0 dB insertion loss plus 6.0 dB impedance matching loss) for the filter. The output of the IF amplifier is buffered and the impedance is 330  $\Omega$ .

### Limiter

The limiter section is similar to the IF amplifier section except that five differential stages are used. The fixed internal input impedance is 330  $\Omega$ . The total gain of the limiting amplifier section is approximately 70 dB. This IF limiting amplifier section internally drives the quadrature detector section and it is also brought out on Pin 12.

### Quadrature Detector

The quadrature detector is a doubly balanced four quadrant multiplier with an internal 5.0 pF quadrature capacitor between Pins 12 and 13. An external capacitor may be added between these pins to increase the IF signal to the external parallel RLC resonant circuit that provides the 90 degree phase shift and drives the quadrature detector. A single pin (Pin 13) provides for the external LC parallel resonant network and the internal connection to the quadrature detector.

Internal low pass filter capacitors have been selected to control the bandwidth of the detector. The recovered signal is brought out by the inverting amplifier buffer. An external feedback resistor from the output (Pin 17) to the input of the inverting amplifier (Pin 15) controls the output amplitude; it is combined with another external resistor from the input to the negative supply (Pin 16) to set the output dc level. For a resistor ratio of 1, the DC level at the detector output is  $2.0 V_{BE}$  (see Figure 12). A small capacitor  $C_{17}$  across the first resistor (from Pin 17 to 15) can be used to reduce the bandwidth.

### Data Slicer

The data slicer is a comparator that is designed to square up the data signal. Across the data slicer inputs (Pins 18 and 20) are back to back diodes.

# MC13158

The recovered data signal from the quadrature detector can be DC coupled to the data slicer DS IN1 (Pin 18). In the application circuit shown in Figure 1 it will be centered at  $2.0 V_{BE}$  and allowed to swing  $\pm V_{BE}$ . A capacitor is placed from DS IN2 (Pin 20) to  $V_{EE}$ . The size of this capacitor and the nature of the data signal determine how faithfully the data slicer shapes up the recovered signal. The time constant is short for large peak to peak voltage swings or when there is a change in DC level at the detector output. For small signal or for continuous bits of the same polarity which drift close to the threshold voltage, the time constant is longer.

A unique feature of the data slicer is that the inverting switching stages in the comparator are supplied through the emitter pin of the output transistor (Pin 22 – DS Gnd) to  $V_{EE}$  rather than internally to  $V_{EE}$ . This is provided in order to reduce switching feedback to the front end. A control pin is provided to shut the data slicer output off (DS “off” – Pin 19). With DS “off” pin at  $V_{CC}$  the data slicer output is shut off by shutting down the base drive to the output transistor. When a channel is being monitored to make an RSSI measurement, but not to collect data, the data output may be shut off to save current.

## PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
1 2	Mix Out $V_{CC1}$		<p><b>Mixer Output</b> The mixer output impedance is 330 <math>\Omega</math>; it matches to 10.7 MHz ceramic filters with 330 <math>\Omega</math> input impedance.</p> <p><b>Supply Voltage (<math>V_{CC1}</math>)</b> This pin is the <math>V_{CC}</math> pin for the Mixer, Local Oscillator, and IF Amplifier. The operating supply voltage range is from 1.8 Vdc to 5.0 Vdc. In the PCB layout, the <math>V_{CC}</math> trace must be kept as wide as possible to minimize inductive reactances along the trace; it is best to have it completely fill around the surface mount components and traces on the circuit side of the PCB.</p>
3 4 5	IF In IF Dec1 IF Dec2		<p><b>IF Input</b> The input impedance at Pin 3 is 330 <math>\Omega</math>. It matches the 330 <math>\Omega</math> load impedance of a 10.7 MHz ceramic filter. Thus, no external matching is required.</p> <p><b>IF DEC1 &amp; DEC2</b> IF decoupling pins. Decoupling capacitors should be placed directly at the pins to enhance stability. Two capacitors are decoupled to the RF ground <math>V_{CC1}</math>; one is placed between DEC1 &amp; DEC2.</p>
6	IF Out		<p><b>IF Output</b> The output impedance is 330 <math>\Omega</math>; it matches the 330 input resistance of a 10.7 MHz ceramic filter.</p>

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
7 8 9 10	$V_{CC2}$ Lim In Lim Dec1 Lim Dec2		<p><b>Supply Voltage (<math>V_{CC2}</math>)</b> This pin is <math>V_{CC}</math> supply for the Limiter, Quadrature Detector, data slicer and RSSI buffer circuits. In the application PC board this pin is tied to a common <math>V_{CC}</math> trace with <math>V_{CC1}</math>.</p> <p><b>Limiter Input</b> The limiter input impedance is 330 <math>\Omega</math>.</p> <p><b>Limiter Decoupling</b> Decoupling capacitors are placed directly at these pins and to <math>V_{CC}</math> (RF ground). Use the same procedure as in the IF decoupling.</p>
11,14, 27 & 28	N/C		<p><b>No Connects</b> There is no internal connection to these pins; however it is recommended that these pins be connected externally to <math>V_{CC}</math> (RF ground).</p>
12 13	Lim Out Quad		<p><b>Limiter Output</b> The output impedance is low. The limiter drives a quadrature detector circuit with in-phase and quadrature phase signals.</p> <p><b>Quadrature Detector Circuit</b> The quadrature detector is a doubly balanced four-quadrant multiplier with an internal 5.0 pF capacitor between Pins 12 and 13. An external capacitor may be added to increase the IF signal to Pin 13. The quadrature detector pin is provided to connect the external RLC parallel resonant network which provides the 90 degree phase shift and drives the quadrature detector.</p>
15 17 16	Det Gain Det Out $V_{EE2}$		<p><b>Detector Buffer Amplifier</b> This is an inverting amplifier. An external feedback resistor from Pin 17 to 15, (the inverting input) controls the output amplitude; another resistor from Pin 15 to the negative supply (Pin 16) sets the DC output level. A 1:1 resistor ratio sets the output DC level at two <math>V_{BE}</math> with respect to <math>V_{EE}</math>. A small capacitor from Pin 17 to 15 can be used to set the bandwidth.</p> <p><b>Supply Ground (<math>V_{EE2}</math>)</b> In the PCB layout, the ground pins (also applies to Pin 26) should be connected directly to chassis ground. Decoupling capacitors to <math>V_{CC}</math> should be placed directly at the ground pins.</p>

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements	
19	DS "off"		<p><b>Data Slicer Off</b> The data output may be shut off to save current by placing DS "off" (Pin 19) at <math>V_{CC}</math>.</p> <p><b>Data Slicer Output</b> In the application example a 10 k<math>\Omega</math> pull-up resistor is connected to the collector of the output transistor at Pin 21.</p> <p><b>Data Slicer Ground</b> All the inverting switching stages in the comparator are supplied through the emitter pin of the output transistor (Pin 22) to ground rather than internally to <math>V_{EE}</math> in order to reduce switching feedback to the front end.</p>	
21	DS Out			<p><b>Data Slicer Inputs</b> The data slicer has differential inputs with back to back diodes across them. The recovered signal is DC coupled to DS IN1 (Pin 18) at nominally <math>V_{18}</math> with respect to <math>V_{EE}</math>; thus, it will maintain <math>V_{18} \pm V_{BE}</math> at Pin 18. DS IN2 (Pin 20) is AC coupled to <math>V_{EE}</math>. The choice of coupling capacitor is dependent on the nature of the data signal. For small signal or continuous bits of the same polarity, the response time is relatively large. On the other hand, for large peak to peak voltage swings or when the DC level at the detector output changes, the response time is short. See the discussion in the application section for external circuit design details.</p>
22	DS Gnd			<p><b>RSSI Buffer</b> A unity gain amplifier is used to buffer the voltage at Pin 24 to 23. The output of the unity gain buffer (Pin 23) has an active pull up but no pull down. An external resistor is placed from Pin 23 to <math>V_{EE}</math> to provide the pull down.</p> <p><b>RSSI</b> The RSSI output current creates a voltage drop across an external resistor from Pin 24 to <math>V_{EE}</math>. The maximum RSSI current is 26 <math>\mu A</math>; thus, the maximum RSSI voltage using a 100 k<math>\Omega</math> resistor is approximately 2.6 Vdc. Figure 22 shows the RSSI Output Voltage versus Input Signal Level in the application circuit.</p> <p>The negative slew rate is determined by an external capacitor and resistor to <math>V_{EE}</math> (negative supply). The RSSI rise and fall times for various RF input signal levels and <math>R_{24}</math> values without the capacitor, <math>C_{24}</math> are displayed in Figure 24. This is the maximum response time of the RSSI.</p>

## APPLICATIONS INFORMATION

### Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side (see Figures 29 and 30). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. This evaluation board will be discussed and referenced in this section.

### Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers and coil types. Figures 13 and 14 show the placement for the components specified in the application circuit (Figure 12). The application circuit schematic specifies particular components that were used to achieve the results shown in the typical curves and tables but alternate components should give similar results.

# MC13158

Figure 12. Application Circuit

- NOTES:**
1. Saw Filter – Siemens part number Y6970M(5 pin SIP plastic package).
  2. An LCR filter reduces the broadband noise in the IF; ceramic filters may be used for data rates under 500 kHz. 4.0 dB insertion loss filters optimize the linearity of RSSI.
  3. The quadrature tank components are chosen to optimize linearity of the recovered signal while maintaining adequate recovered signal level. 1.5 μH 7.0 mm variable shielded inductor: Toko part # 292SNS-T1373Z. The shunt resistor is approximately equal to  $Q(2\pi fL)$ , where  $Q \sim 18$  (3.0 dB BW = 600 kHz).
  4. The local oscillator circuit utilizes a 122.7 MHz, 5th overtone, series resonant crystal specified with a frequency tolerance of 25 PPM, ESR of 120 Ω max. The oscillator configuration is an emitter coupled butler.
  5. The 95 nH (Nominal) inductor is a 7.0 mm variable shielded inductor: Coilcraft part # 150-04J08S or equivalent.
  6. 0.68 μH axial lead chokes (molded inductor): Coilcraft part # 90-11.
  7. To enable the IC, Pin 25 is taken to V<sub>EE</sub>. The external pull down resistor at Pin 29 could be linked to the enable function; otherwise if it is taken to V<sub>EE</sub> as shown, it will keep the oscillator biased at about 500 μA depending on the V<sub>CC</sub> level.
  8. The other resistors and capacitors are surface mount components.

# MC13158

Figure 14. Ground Side Component Placement

### Input Matching/Components

It is desirable to use a SAW filter before the mixer to provide additional selectivity and adjacent channel rejection. In a wideband system the primary sensitivity of the receiver backend may be achieved before the last mixer. Bandpass filtering in the limiting IF is costly and difficult to achieve for bandwidths greater than 280 kHz.

The SAW filter should be selected to easily interface with the mixer differential input impedance of approximately 2.0 k $\Omega$  in parallel with 1.0 pF. The PC board is dedicated to the Siemens SAW filter (part number Y6970M); the part is designed for DECT at 112 MHz 1st IF frequency. It is designed for a load impedance of 2.0 k $\Omega$  in parallel with

2.0 pF; thus, no or little input matching is required between the SAW filter and the mixer.

The Siemens SAW filter has an insertion loss of typically 10 dB and a 3.0 dB bandwidth of 1.0 MHz. The relatively high insertion loss significantly contributes to the system noise and a filter having lower insertion loss would be desirable. In existing low loss SAW filters, the required load impedance is 50  $\Omega$ ; thus, interface matching between the filter and the mixer will be required. Figure 15 is a table of the single-ended mixer input impedance. A careful noise analysis is necessary to determine the secondary contribution to system noise.

**Figure 15. Mixer Input Impedance**  
(Single-ended)

f (MHz)	R <sub>s</sub> ( $\Omega$ )	X <sub>s</sub> ( $\Omega$ )	R <sub>p</sub> ( $\Omega$ )	X <sub>p</sub> ( $\Omega$ )	C <sub>p</sub> (pF)
50	930	-350	1060	-2820	1.1
100	480	-430	865	-966	1.6
150	270	-400	860	-580	1.8
200	170	-320	770	-410	1.9
250	130	-270	690	-330	1.85
300	110	-250	680	-300	1.8
400	71	-190	580	-220	1.8
500	63	-140	370	-170	1.9
600	49	-110	300	-130	2.0

### System Noise Considerations

The system block diagram in Figure 16 shows the cascaded noise stages contributing to the system noise; it represents the application circuit in Figure 12 and a low noise preamp using a MRF941 transistor (see Figure 17). The preamp is designed for a conjugately matched input and output at 2.0 Vdc V<sub>CE</sub> and 3.0 mA I<sub>C</sub>. S-parameters at 2.0 V, 3.0 mA and 100 MHz are:

$$\begin{aligned} S_{11} &= 0.86, -20 \\ S_{21} &= 9.0, 164 \\ S_{12} &= 0.02, 79 \\ S_{22} &= 0.96, -12 \end{aligned}$$

The bias network sets V<sub>CE</sub> at 2.0 V and I<sub>C</sub> at 3.0 mA for V<sub>CC</sub> = 3.0 to 3.5 Vdc. The preamp operates with 18 dB gain and 2.7 dB noise figure.

In the cascaded noise analysis the system noise equation is:

$$F_{\text{system}} = F_1 + [(F_2 - 1)/G_1] + [(F_3 - 1)]/[(G_1)(G_2)]$$

where:

- F1 = the Noise Factor of the Preamp
- G1 = the Gain of the Preamp
- F2 = the Noise factor of the SAW Filter
- G2 = the Gain of the SAW Filter
- F3 = the Noise factor of the Mixer

**Note:** the proceeding terms are defined as linear relationships and are related to the log form for gain and noise figure by the following:

$$F = \log^{-1}[(\text{NF in dB})/10] \quad \text{and similarly}$$

$$G = \log^{-1}[(\text{Gain in dB})/10]$$

The noise figure and gain measured in dB are shown in the system block diagram. The mixer noise figure is typically 14 dB and the SAW filter adds typically 10 dB insertion loss. Addition of a low noise preamp having a 18 dB gain and 2.7 dB noise figure not only improves the system noise figure but it increases the reverse isolation from the local oscillator to the antenna input at the receiver. Calculating in terms of gain and noise factor yields the following:

$$\begin{aligned} F_1 &= 1.86; \quad G_1 = 63.1 \\ F_2 &= 10; \quad G_2 = 0.1 \\ F_3 &= 25.12 \end{aligned}$$

Thus, substituting in the equation for system noise factor:

$$F_{\text{system}} = 5.82; \quad \text{NF}_{\text{system}} = 7.7 \text{ dB}$$

Figure 16. System Block Diagram for Noise Analysis

Figure 17. 112 MHz LNA

LOCAL OSCILLATORS

VHF Applications

The on-chip grounded collector transistor may be used for HF and VHF local oscillator with higher order overtone crystals. The local oscillator in the application circuit (Figure 12) shows a 5th overtone oscillator at 122.7 MHz. This circuit uses a Butler overtone oscillator configuration. The amplifier is an emitter follower. The crystal is driven from the emitter and is coupled to the high impedance base through a capacitive tap network. Operation at the desired overtone frequency is ensured by the parallel resonant circuit formed by the variable inductor and the tap capacitors and parasitic capacitances of the on-chip transistor and PC board. The variable inductor specified in the schematic could be replaced with a high tolerance, high Q ceramic or air wound surface mount component if the other components have tight enough tolerances. A variable inductor provides an adjustment for gain and frequency of the resonant tank ensuring lock up and start-up of the crystal oscillator. The overtone crystal is chosen with ESR of typically 80 Ω and 120 Ω maximum; if the resistive loss in the crystal is too high the performance of oscillator may be impacted by lower gain margins.

A series LC network to ground (which is V<sub>CC</sub>) is comprised of the inductance of the base lead of the on-chip transistor and PC board traces and tap capacitors. Parasitic oscillations often occur in the 200 to 800 MHz range. A small resistor is placed in series with the base (Pin 28) to cancel the

negative resistance associated with this undesired mode of oscillation. Since the base input impedance is so large a small resistor in the range of 27 to 68 Ω has very little effect on the desired Butler mode of oscillation.

The crystal parallel capacitance, C<sub>O</sub>, provides a feedback path that is low enough in reactance at frequencies of 5th overtones or higher to cause trouble. C<sub>O</sub> has little effect near resonance because of the low impedance of the crystal motional arm (R<sub>m</sub>-L<sub>m</sub>-C<sub>m</sub>). As the tunable inductor which forms the resonant tank with the tap capacitors is tuned "off" the crystal resonant frequency it may be difficult to tell if the oscillation is under crystal control. Frequency jumps may occur as the inductor is tuned. In order to eliminate this behavior an inductor, L<sub>O</sub>, is placed in parallel with the crystal. L<sub>O</sub> is chosen to be resonant with the crystal parallel capacitance, C<sub>O</sub>, at the desired operation frequency. The inductor provides a feedback path at frequencies well below resonance; however, the parallel tank network of the tap capacitors and tunable inductor prevent oscillation at these frequencies.

IF Filtering/Matching

In wideband data systems the IF bandpass needed is greater than can be found in low cost ceramic filters operating at 10.7 MHz. It is necessary to bandpass limit with LC networks or series-parallel ceramic filter networks. Murata offers a series-parallel resonator pair (part number

KMFC545) with a 3.0 dB bandwidth of ±325 kHz and a maximum insertion loss of 5.0 dB. The application PC board is laid out to accommodate this filter pair (a filter pair is used at both locations of the split IF). However, even using a series parallel ceramic filter network yields only a maximum bandpass of 650 kHz. In some applications a wider band IF bandpass is necessary.

A simple LC network yields a bandpass wider than the SAW filter but it does reduce an appreciable amount of wideband IF noise. In the application circuit an LC network is specified using surface mount components. The parallel LC components are placed between the outputs of the mixer and IF amplifier to the V<sub>CC</sub> trace; internal 330 loads are connected from the mixer and IF amplifier outputs to DEC2 (Pin 5 and 10 respectively). This loads the outputs with the optimal load impedance but creates a low insertion loss filter. An external shunt resistor may be used to widen the bandpass and to acquire the 10 dB composite loss necessary to linearize the RSSI output. The equivalent circuit is shown in Figure 18.

Figure 18. IF LCR Filter

The following equations satisfy the 12 dB loss (1:4 resistive ratio):

$$\begin{aligned} \text{Rext}(330)/(\text{Rext} + 330) &= \text{Requivalent} \\ \text{Requivalent}/(\text{Requivalent} + 330) &= 1/4 \end{aligned}$$

Solve for Requivalent:

$$\begin{aligned} 4(\text{Requivalent}) &= \text{Requivalent} + 330 \\ 3(\text{Requivalent}) &= 330 \\ \text{Requivalent} &= 110 \end{aligned}$$

Substitute for Requivalent and solve for Rext:

$$\begin{aligned} 330(\text{Rext}) &= 110(\text{Rext}) + (330)(110) \\ \text{Rext} &= (330)(110)/220 \\ \text{Rext} &= 165 \Omega \end{aligned}$$

The IF is 10.7 MHz although any IF between 10 to 20 MHz could be used. The value of the coil is lowered from that used in the quadrature circuit because the unloaded Q must be maintained in a surface mount component. A standard value component having an unloaded Q = 100 at 10.7 MHz is 330 nH; therefore the capacitor is 669 pF. Standard values have been chosen for these components;

$$\begin{aligned} \text{Rext} &= 150 \Omega \\ \text{C} &= 680 \text{ pF} \\ \text{L} &= 330 \text{ nH} \end{aligned}$$

Computation of the loaded Q of this LCR network is

$$Q = \text{Requivalent}/X_L$$

where:  $X_L = 2\pi fL$  and Requivalent is 103 Ω

$$\text{Thus, } Q = 4.65$$

The total system loss is

$$20 \log (103/433) = -12.5 \text{ dB}$$

### Quadrature Detector

The quadrature detector is coupled to the IF with an internal 5.0 pF capacitor between Pins 12 and 13. For wideband data applications, the drive to the detector can be increased with an additional external capacitor between these pins; thus, the recovered signal level output is increased for a given bandwidth

The wideband performance of the detector is controlled by the loaded Q of the LC tank circuit. The following equation defines the components which set the detector circuit's bandwidth:

$$Q = R_T/X_L \tag{1}$$

where  $R_T$  is the equivalent shunt resistance across the LC Tank

$X_L$  is the reactance of the quadrature inductor at the IF frequency ( $X_L = 2\pi fL$ ).

The inductor and capacitor are chosen to form a resonant LC tank with the PCB and parasitic device capacitance at the desired IF center frequency as predicted by

$$f_c = [2\pi (LC_p)^{1/2}]^{-1} \tag{2}$$

where L is the parallel tank inductor  $C_p$  is the equivalent parallel capacitance of the parallel resonant tank circuit.

The following is a design example for a wideband detector at 10.7 MHz and a loaded Q of 18. The loaded Q of the quadrature detector is chosen somewhat less than the Q of the IF bandpass. For an IF frequency of 10.7 MHz and an IF bandpass of 600 kHz, the IF bandpass Q is approximately 6.4.

### Example:

Let the external  $C_{ext} = 139 \text{ pF}$ . (The minimum value here should be much greater than the internal device and PCB parasitic capacitance,  $C_{int} \approx 3.0 \text{ pF}$ ). Thus,  $C_p = C_{int} + C_{ext} = 142 \text{ pF}$ .

Rewrite equation (2) and solve for L:

$$L = (0.159)^2/(C_p f_c^2)$$

$$L = 1.56 \mu\text{H}; \text{ Thus, a standard value is}$$

chosen:

$$L = 1.56 \mu\text{H (tunable shielded inductor)}$$

The value of the total damping resistor to obtain the required loaded Q of 18 can be calculated by rearranging equation (1):

$$R_T = Q(2\pi fL)$$

$$R_T = 18(2\pi)(10.7)(1.5) = 1815 \Omega$$

# MC13158

The internal resistance,  $R_{int}$  at the quadrature tank Pin 13 is approximately 13 k $\Omega$  and is considered in determining the external resistance,  $R_{ext}$  which is calculated from

$$R_{ext} = ((R_T)(R_{int})) / (R_{int} - R_T)$$

$$R_{ext} = 2110; \text{ Thus, choose the standard value:}$$

$$R_{ext} = 2.2 \text{ k}\Omega$$

It is important to set the DC level of the detector output at Pin 17 to center the peak to peak swing of the recovered signal. In the equivalent internal circuit shown in the Pin Function Description, the reference voltage at the positive terminal of the inverting op amp buffer amplifier is set at 1.0  $V_{BE}$ . The detector DC level,  $V_{17}$  is determined by the following equation:

$$V_{17} = [((R_{15}/R_{17}) + 1) / (R_{15}/R_{17})] V_{BE}$$

Thus, for a 1:1 ratio of  $R_{15}/R_{17}$ ,  $V_{17} = 2.0 V_{BE} = 1.4 \text{ Vdc}$ . Similarly for a 2:1,  $V_{17} = 1.5 V_{BE} = 1.05 \text{ Vdc}$ ; and for 3:1,  $V_{17} = 1.33 V_{BE} = 0.93 \text{ Vdc}$ .

Figure 19 shows the detector "S-Curves", in which the resistor ratio is varied while maintaining a constant gain ( $R_{17}$  is held at 62 k).  $R_{15}$  is 62 k for a 1:1 ratio; while  $R_{15} = 120 \text{ k}$  and  $180 \text{ k}$  to produce the 2:1 and 3:1 ratios. The IF signal into the detector is swept  $\pm 500 \text{ kHz}$  about the 10.7 MHz IF center frequency. The resulting curve show how the resistor ratio and the supply voltage effects the symmetry of the "S-curve" (Figure 21 Test Setup). For the 3:1 and 2:1 ratio, symmetry is maintained with  $V_S$  from 2.0 to 5.0 Vdc; however, for the 1:1 ratio, symmetry is lost at 2.0 Vdc.

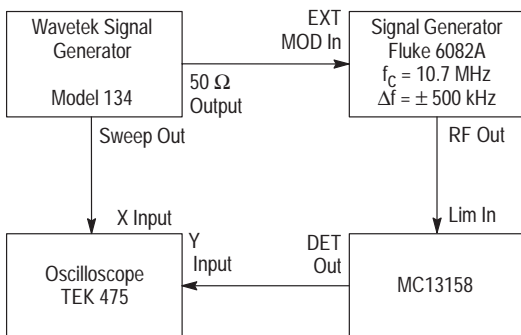

Figure 20. Demodulator "S-Curve" Test Setup

## Data Slicer Circuit

$C_{20}$  at the input of the data slicer is chosen to maintain a time constant long enough to hold the charge on the capacitor for the longest strings of bits at the same polarity. For a data rate at 576 kHz a bit stream of 15 bits at the same polarity would equate to an apparent data rate of approximately 77 kbps or 38 kHz. The time constant would be approximately 26  $\mu\text{s}$ . The following expression equates the time constant,  $t$ , to the external components:

$$t = 2\pi (R_{18})(C_{20})$$

Solve for  $C_{20}$ :

$$C_{20} = t / 2\pi (R_{18})$$

where the effective resistance  $R_{18}$  is a complex function of the demodulator feedback resistance and the data slicer input circuit. In the data input network the back to back diodes form a charge and discharge path for the capacitor at Pin 20; however, the diodes create a non-linear response. This resistance is loaded by the  $\beta$ , beta of the detector output transistor; beta = 100 is a typical value (see Figure 21). Thus, the apparent value of the resistance at Pin 18 (DS IN1) is approximately equal to:

$$R_{18} \sim R_{17} / 100$$

where  $R_{17}$  is 82 k $\Omega$ , the feedback resistor from Pin 17 to 15. Therefore, substituting for  $R_{18}$  and solving for  $C_{20}$ :

$$C_{20} = 15.9 (t) / R_{17} = 5.04 \text{ nF}$$

The closest standard value is 4.7 nF.

## SYSTEM PERFORMANCE DATA

### RSSI

In Figure 22, the RSSI versus RF Input Level shows the linear response of RSSI over a 65 dB range but it has extended capability over 80 dB from  $-80$  dBm to  $+10$  dBm. The RSSI is measured in the application circuit (Figure 12) in which a SAW filter is used before the mixer; thus, the overall sensitivity is compromised for the sake of selectivity. The curves are shown for three filters having different bandwidths:

- 1) LCR Filter with 2.3 MHz 3.0 dB BW (Circuit and Component Placement is shown in Figure 12)
- 2) Series-Parallel Ceramic Filter with 650 kHz 3.0 dB BW (Murata Part # KMFC-545)
- 3) Ceramic Filter with 280 kHz 3.0 dB BW.

**Figure 22. RSSI Output Voltage versus Signal Input Level**

### SINAD Performance

Figure 24 shows a test setup for a narrowband demodulator output response in which a C-message filter and an active de-emphasis filter is used following the demodulator. The input is matched using a 1:4 impedance transformer. The SINAD performance is shown in Figure 25 with no preamp and in Figure 26 with a preamp (Preamp – Figure 16). The 12 dB SINAD sensitivity is  $-101$  dBm with no preamp and  $-113$  dBm with the preamp.

# UHF FM/AM Transmitter

The MC13176 is a one chip FM/AM transmitter subsystem designed for AM/FM communication systems. It include a Colpitts crystal reference oscillator, UHF oscillator,  $\times 32$  prescaler and phase detector forming a versatile PLL system. Targeted applications are in the 260 to 470 MHz band and the 902 to 928 MHz band covered by FCC Title 47; Part 15. Other applications include local oscillator sources in UHF and 900 MHz receivers, UHF and 900 MHz video transmitters, RF Local Area Networks (LANs), and high frequency clock drivers. The MC13176 offers the following features:

- UHF Current Controlled Oscillator
- Uses Easily Available 3rd Overtone or Fundamental Crystals for Reference
- Fewer External Parts Required
- Low Operating Supply Voltage (1.8 to 5.0 Vdc)
- Low Supply Drain Currents
- Power Output Adjustable (Up to 10 dBm)
- Differential Output for Loop Antenna or Balun Transformer Networks
- Power Down Feature
- ASK Modulated by Switching Output On and Off
- $f_o = 32 \times f_{ref}$

## PIN FUNCTION DESCRIPTIONS

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
1 & 4	Osc 1, Osc 4		<p><b>CCO Inputs</b></p> <p>The oscillator is a current controlled type. An external oscillator coil is connected to Pins 1 and 4 which forms a parallel resonance LC tank circuit with the internal capacitance of the IC and with parasitic capacitance of the PC board. Three base-emitter capacitances in series configuration form the capacitance for the parallel tank. These are the base-emitters at Pins 1 and 4 and the base-emitter of the differential amplifier. The equivalent series capacitance in the differential amplifier is varied by the modulating current from the frequency control circuit (see Pin 6, internal circuit). A more thorough discussion is found in the Applications Information section.</p>
5	V <sub>EE</sub>		<p><b>Supply Ground (V<sub>EE</sub>)</b></p> <p>In the PCB layout, the ground pins (also applies to Pins 10 and 15) should be connected directly to chassis ground. Decoupling capacitors to V<sub>CC</sub> should be placed directly at the ground returns.</p>
6	I <sub>Cont</sub>		<p><b>Frequency Control</b></p> <p>For V<sub>CC</sub> = 3.0 Vdc, the voltage at Pin 6 is approximately 1.55 Vdc. The oscillator is current controlled by the error current from the phase detector. This current is amplified to drive the current source in the oscillator section which controls the frequency of the oscillator. Figures 8 and 9 show the <math>\Delta f_{osc}</math> versus I<sub>Cont</sub>. Figure 5 shows the <math>\Delta f_{osc}</math> versus I<sub>Cont</sub> at -40°C, +25°C and +85°C for 320 MHz. The CCO may be FM modulated as shown in Figures 17 and 18, MC13176 320 MHz FM Transmitter. A detailed discussion is found in the Applications Information section.</p>
7	PD <sub>Out</sub>		<p><b>Phase Detector Output</b></p> <p>The phase detector provides <math>\pm 30 \mu A</math> to keep the CCO locked at the desired carrier frequency. The output impedance of the phase detector is approximately 53 k<math>\Omega</math>. Under closed loop conditions there is a DC voltage which is dependent upon the free running oscillator and the reference oscillator frequencies. The circuitry between Pins 7 and 6 should be selected for adequate loop filtering necessary to stabilize and filter the loop response. Low pass filtering between Pin 7 and 6 is needed so that the corner frequency is well below the sum of the divider and the reference oscillator frequencies, but high enough to allow for fast response to keep the loop locked. Refer to the Applications Information section regarding loop filtering and FM modulation.</p>

PIN FUNCTION DESCRIPTIONS

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
8	Xtaleb		<p><b>Crystal Oscillator Inputs</b></p> <p>The internal reference oscillator is configured as a common emitter Colpitts. It may be operated with either a fundamental or overtone crystal depending on the carrier frequency and the internal prescaler. Crystal oscillator circuits and specifications of crystals are discussed in detail in the applications section. With <math>V_{CC} = 3.0</math> Vdc, the voltage at Pin 8 is approximately 1.8 Vdc and at Pin 9 is approximately 2.3 Vdc. 500 to 1000 mVp-p should be present at Pin 9. The Colpitts is biased at 200 <math>\mu</math>A; additional drive may be acquired by increasing the bias to approximately 500 <math>\mu</math>A. Use 6.2 k from Pin 8 to ground.</p>
9	Xtaleb		
10	Reg. Gnd		<p><b>Regulator Ground</b></p> <p>An additional ground pin is provided to enhance the stability of the system. Decoupling to the <math>V_{CC}</math> (RF ground) is essential; it should be done at the ground return for Pin 10.</p>
11	Enable		<p><b>Device Enable</b></p> <p>The potential at Pin 11 is approximately 1.25 Vdc. When Pin 11 is open, the transmitter is disabled in a power down mode and draws less than 1.0 <math>\mu</math>A <math>I_{CC}</math> if the MOD at Pin 16 is also open (i.e., it has no current driving it). To enable the transmitter a current source of 10 <math>\mu</math>A to 90 <math>\mu</math>A is provided. Figures 3 and 4 show the relationship between <math>I_{CC}</math>, <math>V_{CC}</math> and <math>I_{reg. enable}</math>. Note that <math>I_{CC}</math> is flat at approximately 10 mA for <math>I_{reg. enable} = 5.0</math> to 100 <math>\mu</math>A (<math>I_{mod} = 0</math>).</p>
12	$V_{CC}$		<p><b>Supply Voltage (<math>V_{CC}</math>)</b></p> <p>The operating supply voltage range is from 1.8 Vdc to 5.0 Vdc. In the PCB layout, the <math>V_{CC}</math> trace must be kept as wide as possible to minimize inductive reactances along the trace; it is best to have it completely fill around the surface mount components and traces on the circuit side of the PCB.</p>
13 & 14	Out 1 and Out 2		<p><b>Differential Output</b></p> <p>The output is configured differentially to easily drive a loop antenna. By using a transformer or balun, as shown in the application schematic, the device may then drive an unbalanced low impedance load. Figure 6 shows how much the Output Power and Free-Running Oscillator Frequency change with temperature at 3.0 Vdc; <math>I_{mod} = 2.0</math> mA.</p>
15	Out_Gnd		<p><b>Output Ground</b></p> <p>This additional ground pin provides direct access for the output ground to the circuit board <math>V_{EE}</math>.</p>
16	$I_{mod}$		<p><b>AM Modulation/Power Output Level</b></p> <p>The DC voltage at this pin is 0.8 Vdc with the current source active. An external resistor is chosen to provide a source current of 1.0 to 3.0 mA, depending on the desired output power level at a given <math>V_{CC}</math>. Figure 27 shows the relationship of Power Output to Modulation Current, <math>I_{mod}</math>. At <math>V_{CC} = 3.0</math> Vdc, 3.5 dBm power output can be acquired with about 35 mA <math>I_{CC}</math>. For FM modulation, Pin 16 is used to set the desired output power level as described above. For AM modulation, the modulation signal must ride on a positive DC bias offset which sets a static (modulation off) modulation current. External circuitry for various schemes is further discussed in the Applications Information section.</p>

APPLICATIONS INFORMATION

Evaluation PC Board

The evaluation PCB, shown in Figures 32 and 33, is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side of the PCB (see Figures 34 and 35). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. This evaluation board will be discussed and referenced in this section.

Current Controlled Oscillator (Pins 1 to 4)

It is critical to keep the interconnect leads from the CCO (Pins 1 and 4) to the external inductor symmetrical and equal in length. With a minimum inductor, the maximum free running frequency is greater than 1.0 GHz. Since this inductor will be small, it may be either a microstrip inductor, an air wound inductor or a tuneable RF coil. An air wound inductor may be tuned by spreading the windings, whereas tuneable RF coils are tuned by adjusting the position of an aluminum core in a threaded coilform. As the aluminum core coupling to the windings is increased, the inductance is decreased. The temperature coefficient using an aluminum core is better than a ferrite core. The UniCoil™ inductors made by Coilcraft may be obtained with aluminum cores (Part No. 51-129-169).

Ground (Pins 5, 10 and 15)

**Ground Returns:** It is best to take the grounds to a backside ground plane via plated through holes or eyelets at the pins. The application PCB layout implements this technique. Note that the grounds are located at or less than 100 mils from the devices pins.

**Decoupling:** Decoupling each ground pin to  $V_{CC}$  isolates each section of the device by reducing interaction between sections and by localizing circulating currents.

Loop Characteristics (Pins 6 and 7)

Figure 10 is the component block diagram of the MC13176D PLL system where the loop characteristics are described by the gain constants. Access to individual components of this PLL system is limited, inasmuch as the loop is only pinned out at the phase detector output and the

frequency control input for the CCO. However, this allows for characterization of the gain constants of these loop components. The gain constants  $K_p$ ,  $K_o$  and  $K_n$  are well defined in the MC13176.

Phase Detector (Pin 7)

With the loop in lock, the difference frequency output of the phase detector is DC voltage that is a function of the phase difference. The sinusoidal type detector used in this IC has the following transfer characteristic:

$$I_e = A \sin \theta_e$$

The gain factor of the phase detector,  $K_p$  (with the loop in lock) is specified as the ratio of DC output current,  $I_e$  to phase error,  $\theta_e$ :

$$K_p = I_e / \theta_e \text{ (Amps/radians)}$$

$$K_p = A \sin \theta_e / \theta_e$$

$$\sin \theta_e \sim \theta_e \text{ for } \theta_e \leq 0.2 \text{ radians;}$$

$$\text{thus, } K_p = A \text{ (Amps/radians)}$$

Figure 7 shows that the detector DC current is approximately 30 μA where the loop loses lock at  $\theta_e = \pm \pi/2$  radians; therefore,  $K_p$  is 30 μA/radians.

Current Controlled Oscillator, CCO (Pin 6)

Figures 8 and 9 show the non-linear change in frequency of the oscillator over an extended range of control current for 320 and 450 MHz applications.  $K_o$  ranges from approximately  $6.3 \times 10^5$  rad/sec/μA or 100 kHz/μA (Figure 8) to  $8.8 \times 10^5$  rad/sec/μA or 140 kHz/μA (Figure 9) over a relatively linear response of control current (0 to 100 μA). The oscillator gain factor depends on the operating range of the control current (i.e., the slope is not constant). Included in the CCO gain factor is the internal amplifier which can sink and source at least 30 μA of input current from the phase detector. The internal circuitry at Pin 6 limits the CCO control current to 50 μA of source capability while its sink capability exceeds 200 μA as shown in Figures 8 and 9. Further information to follow shows how to use the full capabilities of the CCO by addition of an external loop amplifier and filter (see Figure 14). This additional circuitry yields at  $K_o = 0.145$  MHz/μA or  $9.1 \times 10^5$  rad/sec/μA.

Figure 10. Block Diagram of MC1317XD PLL

Where:  $K_p =$  Phase detector gain constant in  $\mu\text{A}/\text{rad}$ ;  $K_p = 30 \mu\text{A}/\text{rad}$   
 $K_f =$  Filter transfer function  
 $K_n = 1/N$ ;  $N = 32$   
 $K_o =$  CCO gain constant in  $\text{rad}/\text{sec}/\mu\text{A}$   
 $K_o = 9.1 \times 10^5 \text{ rad}/\text{sec}/\mu\text{A}$

**Loop Filtering**

The fundamental loop characteristics, such as capture range, loop bandwidth, lock-up time and transient response are controlled externally by loop filtering.

The natural frequency ( $\omega_n$ ) and damping factor ( $\partial$ ) are important in the transient response to a step input of phase or frequency. For a given  $\partial$  and lock time,  $\omega_n$  can be determined from the plot shown in Figure 11.

For  $\partial = 0.707$  and lock time = 1.0 ms;  
 then  $\omega_n = 5.0/t = 5.0 \text{ krad}/\text{sec}$ .

The loop filter may take the form of a simple low pass filter or a lag-lead filter which creates an additional pole at origin in the loop transfer function. This additional pole along with that of the CCO provides two pure integrators ( $1/s^2$ ). In the lag-lead low pass network shown in Figure 12, the values of the low pass filtering parameters  $R_1$ ,  $R_2$  and  $C$  determine the loop constants  $\omega_n$  and  $\partial$ . The equations  $t_1 = R_1C$  and  $t_2 = R_2C$  are related in the loop filter transfer functions  $F(s) = 1 + t_2s/1 + (t_1 + t_2)s$ .

Figure 11. Type 2 Second Order Response

Figure 12. Lag-Lead Low Pass Filter

The closed loop transfer function takes the form of a 2nd order low pass filter given by,

$$H(s) = K_v F(s)/s + K_v F(s)$$

From control theory, if the loop filter characteristic has  $F(0) = 1$ , the DC gain of the closed loop,  $K_v$  is defined as,

$$K_v = K_p K_o K_n$$

and the transfer function has a natural frequency,

$$\omega_n = (K_v/t_1 + t_2)^{1/2}$$

and a damping factor,

$$\partial = (\omega_n/2) (t_2 + 1/K_v)$$

Rewriting the above equations and solving for the MC13176 with  $\partial = 0.707$  and  $\omega_n = 5.0 \text{ k rad}/\text{sec}$ :

$$K_v = K_p K_o K_n = (30) (0.91 \times 10^6) (1/32) = 0.853 \times 10^6$$

$$t_1 + t_2 = K_v/\omega_n^2 = 0.853 \times 10^6/(25 \times 10^6) = 34.1 \text{ ms}$$

$$t_2 = 2\partial/\omega_n = (2) (0.707)/(5 \times 10^3) = 0.283 \text{ ms}$$

$$t_1 = (K_v/\omega_n^2) - t_2 = (34.1 - 0.283) = 33.8 \text{ ms}$$

For  $C = 0.47 \mu$ ;  
 then,  $R_1 = t_1/C = 33.8 \times 10^{-3}/0.47 \times 10^{-6} = 72 \text{ k}$   
 thus,  $R_2 = t_2/C = 0.283 \times 10^{-3}/0.47 \times 10^{-6} = 0.60 \text{ k}$   
 In the above example, the following standard value components are used,

$C = 0.47 \mu$ ;  $R_2 = 620$  and  $R'_1 = 72 \text{ k} - 53 \text{ k} \sim 18 \text{ k}$   
 ( $R'_1$  is defined as  $R_1 - 53 \text{ k}$ , the output impedance of the phase detector.)

Since the output of the phase detector is high impedance ( $\sim 50 \text{ k}$ ) and serves as a current source, and the input to the frequency control, Pin 6 is low impedance (impedance of the two diode to ground is approximately  $500 \Omega$ ), it is imperative that the second order low pass filter design above be modified. In order to minimize loading of the  $R_2C$  shunt network, a higher impedance must be established to Pin 6. A simple solution is achieved by adding a low pass network between the passive second order network and the input to Pin 6. This helps to minimize the loading effects on the second order low pass while further suppressing the sideband spurs of the crystal oscillator. A low pass filter with  $R_3 = 1.0 \text{ k}$  and  $C_2 = 1500 \text{ p}$  has a corner frequency ( $f_c$ ) of  $106 \text{ kHz}$ ; the reference sideband spurs are down greater than  $-60 \text{ dBc}$ .

Figure 13. Modified Low Pass Loop Filter

**Hold-In Range**

The hold-in range, also called the lock range, tracking range and synchronization range, is the ability of the CCO frequency,  $f_o$  to track the input reference signal,  $f_{ref} \cdot N$  as it gradually shifted away from the free running frequency,  $f_f$ . Assuming that the CCO is capable of sufficient frequency deviation and that the internal loop amplifier and filter are not overdriven, the CCO will track until the phase error,  $\theta_e$  approaches  $\pm\pi/2$  radians. Figures 5 through 7 are a direct

measurement of the hold-in range (i.e.  $\Delta f_{ref} \times N = \pm \Delta f_H \times 2\pi$ ). Since  $\sin \theta_e$  cannot exceed  $\pm 1.0$ , as  $\theta_e$  approaches  $\pm\pi/2$  the hold-in range is equal to the DC loop gain,  $K_V \times N$ .

$$\pm \Delta \omega_H = \pm K_V \times N$$

where,  $K_V = K_P K_O K_n$ .

In the above example,

$$\pm \Delta \omega_H = \pm 27.3 \text{ Mrad/sec}$$

$$\pm \Delta f_H = \pm 4.35 \text{ MHz}$$

**Extended Hold-in Range**

The hold-in range of about 3.4% could cause problems over temperature in cases where the free-running oscillator drifts more than 2 to 3% because of relatively high temperature coefficients of the ferrite tuned CCO inductor. This problem might worsen for lower frequency applications where the external tuning coil is large compared to internal capacitance at Pins 1 and 4. To improve hold-in range performance, it is apparent that the gain factors involved must be carefully considered.

$K_n$  = is 1/32 in the MC13176.

$K_p$  = is fixed internally and cannot be altered.

$K_o$  = Figures 8 and 9 suggest that there is capability of greater control range with more current swing. However, this swing must be symmetrical about the center of the dynamic response. The suggested zero current operating point for  $\pm 100 \mu\text{A}$  swing of the CCO is at about  $+70 \mu\text{A}$  offset point.

$K_a$  = External loop amplification will be necessary since the phase detector only supplies  $\pm 30 \mu\text{A}$ .

In the design example in Figure 14, an external resistor ( $R_5$ ) of  $15 \text{ k}$  to  $V_{CC}$  ( $3.0 \text{ Vdc}$ ) provides approximately  $100 \mu\text{A}$  of current boost to supplement the existing  $50 \mu\text{A}$  internal source current.  $R_4$  ( $1.0 \text{ k}$ ) is selected for approximately  $0.1 \text{ Vdc}$  across it with  $100 \mu\text{A}$ .  $R_1$ ,  $R_2$  and  $R_3$  are selected to set the potential at Pin 7 and the base of 2N4402 at approximately  $0.9 \text{ Vdc}$  and the emitter at  $1.55 \text{ Vdc}$  when error current to Pin 6 is approximately zero  $\mu\text{A}$ .  $C_1$  is chosen to reduce the level of the crystal sidebands.

Figure 14. External Loop Amplifier

Figure 15 shows the improved hold-in range of the loop. The  $\Delta f_{ref}$  is moved 950 kHz with over 200  $\mu$ A swing of control current for an improved hold-in range of  $\pm 15.2$  MHz or  $\pm 95.46$  Mrad/sec.

**Figure 15. MC13176 Reference Oscillator Frequency versus Oscillator Control Current**

**Lock-in Range/Capture Range**

If a signal is applied to the loop not equal to free running frequency,  $f_f$ , then the loop will capture or lock-in the signal by making  $f_s = f_o$  (i.e. if the initial frequency difference is not too great). The lock-in range can be expressed as  $\Delta\omega_L \sim \pm 2\delta\omega_n$

**FM Modulation**

Noise external to the loop (phase detector input) is minimized by narrowing the bandwidth. This noise is minimal in a PLL system since the reference frequency is usually derived from a crystal oscillator. FM can be achieved by applying a modulation current superimposed on the control current of the CCO. The loop bandwidth must be narrow enough to prevent the loop from responding to the modulation frequency components, thus, allowing the CCO to deviate in frequency. The loop bandwidth is related to the natural frequency  $\omega_n$ . In the lag-lead design example where the natural frequency,  $\omega_n = 5.0$  krad/sec and a damping factor,  $\delta = 0.707$ , the loop bandwidth = 1.64 kHz. Characterization data of the closed loop responses at 320 MHz (Figure 7) show satisfactory performance using only a simple low-pass loop filter network. The loop filter response is strongly influenced by the high output impedance of the phase detector.

$$f_c = 0.159/RC;$$

For  $R = 1.0 \text{ k} + R_7$  ( $R_7 = 53 \text{ k}$ ) and  $C = 390 \text{ pF}$

$$f_c = 7.55 \text{ kHz or } \omega_c = 47 \text{ krad/sec}$$

The application example in Figure 17 of a 320 MHz FM transmitter demonstrates the FM capabilities of the IC. A high value series resistor (100 k) to Pin 6 sets up the current source to drive the modulation section of the chip. Its value is dependent on the peak to peak level of the encoding data and the maximum desired frequency deviation. The data input is AC coupled with a large coupling capacitor which is selected for the modulating frequency. The component placements on the circuit side and ground side of the PC board are shown in Figures 34 and 35, respectively. Figure 19 illustrates the input data of a 10 kHz modulating signal at 1.6 V<sub>p-p</sub>. Figures 20 and 21 depict the deviation and resulting modulation spectrum showing the carrier null at -40 dBc. Figure 22 shows the unmodulated carrier power output at 3.5 dBm for  $V_{CC} = 3.0$  Vdc.

For voice applications using a dynamic or an electret microphone, an op amp is used to amplify the microphone's low level output. The microphone amplifier circuit is shown in Figure 16. Figure 18 shows an application example for NBFM audio or direct FSK in which the reference crystal oscillator is modulated.

**Figure 16. Microphone Amplifier**

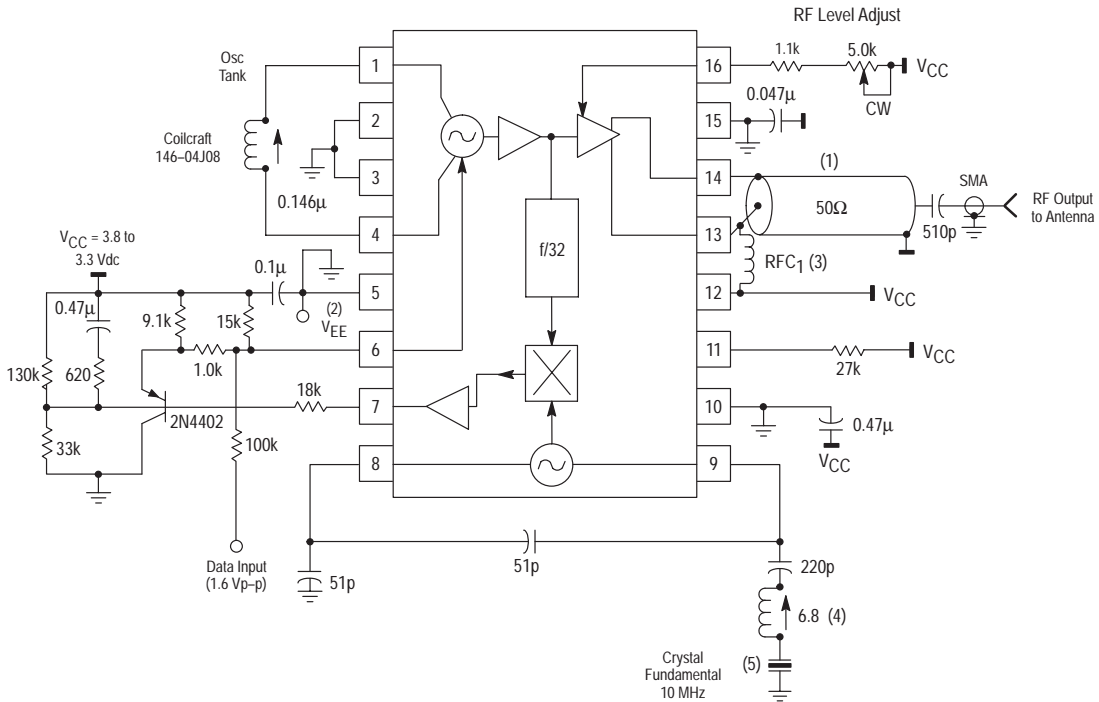

**Local Oscillator Application**

To reduce internal loop noise, a relatively wide loop bandwidth is needed so that the loop tracks out or cancels the noise. This is emphasized to reduce inherent CCO and divider noise or noise produced by mechanical shock and environmental vibrations. In a local oscillator application the CCO and divider noise should be reduced by proper selection of the natural frequency of the loop. Additional low pass filtering of the output will likely be necessary to reduce the crystal sideband spurs to a minimal level.

Figure 22. Unmodulated Carrier

**Reference Crystal Oscillator (Pins 8 and 9)**

**Selection of Proper Crystal:** A crystal can operate in a number of mechanical modes. The lowest resonant frequency mode is its fundamental while higher order modes are called overtones. At each mechanical resonance, a crystal behaves like a RLC series-tuned circuit having a large inductor and a high Q. The inductor  $L_S$  is series resonance with a dynamic capacitor,  $C_S$  determined by the elasticity of the crystal lattice and a series resistance  $R_S$ , which accounts for the power dissipated in heating the crystal. This series RLC circuit is in parallel with a static capacitance,  $C_P$  which is created by the crystal block and by the metal plates and leads that make contact with it.

Figure 23 is the equivalent circuit for a crystal in a single resonant mode. It is assumed that other modes of resonance are so far off frequency that their effects are negligible.

Series resonant frequency,  $f_S$  is given by;

$$f_S = 1/2\pi(L_S C_S)^{1/2}$$

and parallel resonant frequency,  $f_P$  is given by;

$$f_P = f_S(1 + C_S/C_P)^{1/2}$$

Figure 23. Crystal Equivalent Circuit

the frequency separation at resonance is given by;

$$\Delta f = f_P - f_S = f_S[1 - (1 + C_S/C_P)^{-1/2}]$$

Usually  $f_P$  is less than 1% higher than  $f_S$ , and a crystal exhibits an extremely wide variation of the reactance with frequency between  $f_P$  and  $f_S$ . A crystal oscillator circuit is very stable with frequency. This high rate of change of impedance with frequency stabilizes the oscillator, because any significant change in oscillator frequency will cause a large phase shift in the feedback loop keeping the oscillator on frequency.

Manufacturers specify crystal for either series or parallel resonant operation. The frequency for the parallel mode is calibrated with a specified shunt capacitance called a “load capacitance.” The most common value is 30 to 32 pF. If the load capacitance is placed in series with the crystal, the equivalent circuit will be series resonance at the specified parallel-resonant frequency. Frequencies up to 20 MHz use parallel resonant crystal operating in the fundamental mode, while above 20 MHz to about 60 MHz, a series resonant crystal specified and calibrated for operation in the overtone mode is used.

### Application Examples

Two types of crystal oscillator circuits are used in the applications circuits: 1) fundamental mode common emitter Colpitts (Figures 1, 17, 18, and 24), and 2) third overtone impedance inversion Colpitts (also Figures 1 and 24).

The fundamental mode common emitter Colpitts uses a parallel resonant crystal calibrated with a 32 pF load capacitance. The capacitance values are chosen to provide excellent frequency stability and output power of > 500 mVp-p at Pin 9. In Figures 1 and 24, the fundamental mode reference oscillator is fixed tuned relying on the repeatability of the crystal and passive network to maintain the frequency, while in the circuit shown in Figures 17 and 18, the oscillator frequency can be adjusted with the variable inductor for the precise operating frequency.

The reference oscillator can be operated as high as 60 MHz with a third overtone crystal. Therefore, it is possible to use the MC13176 up to 950 MHz (based on the maximum capability of the divider network).

### Enable (Pin 11)

The enabling resistor at Pin 11 is calculated by:

$$R_{\text{reg. enable}} = V_{\text{CC}} - 1.0 \text{ Vdc} / I_{\text{reg. enable}}$$

From Figure 4,  $I_{\text{reg. enable}}$  is chosen to be 75  $\mu\text{A}$ . So, for a  $V_{\text{CC}} = 3.0 \text{ Vdc}$   $R_{\text{reg. enable}} = 26.6 \text{ k}\Omega$ , a standard value 27 k $\Omega$  resistor is adequate.

### Layout Considerations

**Supply (Pin 12):** In the PCB layout, the  $V_{\text{CC}}$  trace must be kept as wide as possible to minimize inductive reactance

along the trace; it is best that  $V_{\text{CC}}$  (RF ground) completely fills around the surface mounted components and interconnect traces on the circuit side of the board. This technique is demonstrated in the evaluation PC board.

### Battery/Selection/Lithium Types

The device may be operated from a 3.0 V lithium battery. Selection of a suitable battery is important. Because one of the major problems for long life battery powered equipment is oxidation of the battery terminals, a battery mounted in a clip-in socket is not advised. The battery leads or contact post should be isolated from the air to eliminate oxide build-up. The battery should have PC board mounting tabs which can be soldered to the PCB. Consideration should be given for the peak current capability of the battery. Lithium batteries have current handling capabilities based on the composition of the lithium compound, construction and the battery size. A 1300 mA/hr rating can be achieved in the cylindrical cell battery. The Rayovac CR2/3A lithium-manganese dioxide battery is a crimp sealed, spiral wound 3.0 Vdc, 1300 mA/hr cylindrical cell with PC board mounting tabs. It is an excellent choice based on capacity and size (1.358" long by 0.665" in diameter).

### Differential Output (Pins 13, 14)

The availability of micro-coaxial cable and small baluns in surface mount and radial-leaded components allows for simple interface to the output ports. A loop antenna may be directly connected with bias via RFC or 50  $\Omega$  resistors. Antenna configuration will vary depending on the space available and the frequency of operation.

### AM Modulation (Pin 16)

**Amplitude Shift Key:** The MC13176 is designed to accommodate Amplitude Shift Keying (ASK). ASK modulation is a form of digital modulation corresponding to AM. The amplitude of the carrier is switched between two or more values in response to the PCM code. For the binary case, the usual choice is On-Off Keying (often abbreviated OOK). The resultant amplitude modulated waveform consists of RF pulses called marks, representing binary 1 and spaces representing binary 0.

# MC13176

Figure 24. ASK 320 MHz Application Circuit

- NOTES:**
1. 50 Ω coaxial balun, 1/10 wavelength line (1.5") provides the best match to a 50 Ω load.
  2. Pins 5, 10 and 15 are ground and connected to V<sub>EE</sub> which is the component/DC ground plane side of PCB. These pins must be decoupled to V<sub>CC</sub>; decoupling capacitors should be placed as close as possible to the pins.

3. The On-Off keyed signal turns the output of the transmitter off and on with TTL level pulses through R<sub>mod</sub> at Pin 16. The "On" power and I<sub>CC</sub> is set by the resistor which sets I<sub>mod</sub> = V<sub>TTL</sub> - 0.8 / R<sub>mod</sub>. (see Figure 27).
4. S1 simulates an enable gate pulse from a microprocessor which will enable the transmitter. (see Figure 4 to determine precise value of the enabling resistor based on the potential of the gate pulse and the desired enable.)

Figure 24 shows a typical application in which the output power has been reduced for linearity and current drain. The current draw on the device is 16 mA I<sub>CC</sub> (average) and -22.5 dBm (average power output) using a 10 kHz modulating rate for the on-off keying. This equates to 20 mA and -2.3 dBm "On", 13 mA and -41 dBm "Off". In Figure 25, the device's modulating waveform and encoded carrier are

displayed. The crystal oscillator enable time is needed to set the acquisition timing. It takes typically 4.0 msec to reach full magnitude of the oscillator waveform (see Figure 26, Oscillator Waveform, at Pin 8). A square waveform of 3.0 V peak with a period that is greater than the oscillator enable time is applied to the Enable (Pin 11).

Figure 25. ASK Input Waveform and Modulated Carrier

Figure 26. Oscillator Enable Time, Tenable

Figure 27. Power Output versus Modulation Current

**Analog AM**

In analog AM applications, the output amplifier's linearity must be carefully considered. Figure 27 is a plot of Power Output versus Modulation Current at 320 MHz, 3.0 Vdc. In order to achieve a linear encoding of the modulating sinusoidal waveform on the carrier, the modulating signal must amplitude modulate the carrier in the linear portion of its power output response. When using a sinewave modulating signal, the signal rides on a positive DC offset called  $V_{mod}$  which sets a static (modulation off) modulation current,  $I_{mod}$ .  $I_{mod}$  controls the power output of the IC. As the modulating signal moves around this static bias point the modulating current varies causing power output to vary or to be AM modulated. When the IC is operated at modulation current levels greater than 2.0 mA the differential output stage starts to saturate.

# MC13176

In the design example, shown in Figure 28, the operating point is selected as a tradeoff between average power output and quality of the AM.

For  $V_{CC} = 3.0\text{Vdc}$ ;  $I_{CC} = 18.5\text{mA}$  and  $I_{mod} = 0.5\text{mA}$  and a static DC offset of  $1.04\text{Vdc}$ , the circuit shown in Figure 28 completes the design. Figures 29, 30 and 31 show the results of  $-6.9\text{dBm}$  output power and 100% modulation by the  $10\text{kHz}$  and  $1.0\text{MHz}$  modulating sinewave signals. The amplitude of the input signals is approximately  $800\text{mVp-p}$ .

Where  $R_{mod} = (V_{CC} - 1.04\text{Vdc})/0.5\text{mA} = 3.92\text{k}$ , use a standard value resistor of  $3.9\text{k}$ .

## Advance Information

# Dual CVSD/PLL Cordless Phone System

The MC33410 Dual CVSD/Cordless Phone system is designed to fit the requirements of a 900 MHz digital cordless telephone system. The device contains a CVSD (Continuously Variable Slope Delta Modulator/Demodulator) Encoder to digitize the speech for the RF transmission, and a CVSD Decoder to reconstruct the received digital speech from the RF receiver. Provisions are made to transmit and receive data as well. Included are three PLLs (Phase-Locked Loops). Two are intended for use with external VCOs and 64/65 or 128/129 dual modulus prescalers, and can control the transmit and receive (LO1) frequencies for the 900 MHz communication. The third PLL is configured as the 2nd local oscillator (LO2), and is functional to 80 MHz. Also included are muting, audio gain adjust (internal and external), low battery/carrier detect, and a wide range for the PLL reference frequency. The power supply range is 2.7 to 5.5 V. A data only (non-voice) mode is also included.

- Two Complete CVSD Sections for Full Duplex Operation
- Two PLLs and an LO Suitable for a 900 MHz System
- Adjustable Detection for Low Battery or Carrier Signal (RSSI)
- Minimal External Components
- Encode Path Includes Adjustable Gain Amplifiers, Filters, Mute, CVSD Encoder, Data Insert, and Scrambler
- Decoder Path Contains Data Slicer, Clock Recovery, Descrambler, Data Detect, CVSD Decoder, Filters, Mute and Power Amplifier
- Data can be Transmitted During Voice Conversation with Minimal or No Noticeable Audio Disruption
- Idle Channel Noise Control
- Independent Power Amplifier with Differential Outputs, Mute
- Selectable Frequency for Switched Capacitor Filters, CVSD Function, PLLs, and the LO
- Reference Frequency Source can be a Crystal or System Clock
- Serial  $\mu$ P Port to Control Gain, Mute, Frequency Selection, Phase Detector Gain, Power Down Modes, Idle Channel Control, Scrambler Operation, Low Battery Detect, and Others
- Mode Available for Data Only Transmission (non-voice)
- Ambient Temperature Range:  $-20$  to  $70^{\circ}\text{C}$
- Power Supply Range: 2.7 to 5.5 V
- Power Down Modes for Power Conservation
- 48 Pin LQFP with 0.5 mm Lead Pitch

## PIN FUNCTION DESCRIPTION

Pin	Name	Description
1	FR <sub>X</sub> MC	Modulus Control Output to the R <sub>X</sub> 64/65 or 128/129 dual modulus prescaler.
2	FR <sub>X</sub>	Input to the R <sub>X</sub> PLL.
3	PLL V <sub>CC</sub>	Supply pin for the R <sub>X</sub> PLL section. Allowable range is 2.7 to 5.5 V.
4	R <sub>X</sub> PD	Phase detector charge pump output of the R <sub>X</sub> PLL.
5	PLL Gnd	Ground pin for the PLL sections.
6	T <sub>X</sub> PD	Phase detector charge pump output of the T <sub>X</sub> PLL.
7	PLL V <sub>CC</sub>	Supply pin for the T <sub>X</sub> PLL section and the MPU Serial Interface section. Allowable range is 2.7 to 5.5 V.
8	FT <sub>X</sub>	Input to the T <sub>X</sub> PLL.
9	FT <sub>X</sub> MC	Modulus Control Output to the T <sub>X</sub> 64/65 or 128/129 dual modulus prescaler.
10	EN	Enable input for the $\mu$ P port. This signal latches in the register address and data.
11	CLK	Clock input for the $\mu$ P port. Maximum frequency is 2.0 MHz.
12	Data	Bi-directional data line for the $\mu$ P port. In Data Modem mode, this pin provides the recovered clock.
13	Status	Logic output which indicates that a predetermined 16 or 24-bit code word has been detected in the Data Detect register, and the following data word has been loaded into register 10. In Data Modem mode, this pin provides the Transmit Data clock.
14, 15	F <sub>ref</sub> In, F <sub>ref</sub> Out	A crystal, in the range of 4.0 to 18.25 MHz can be connected to these pins to provide the reference frequency. If an external reference source is used, it is to be capacitively coupled to F <sub>ref</sub> In.
16	Low Battery/CD	An open collector output. When low, indicates either the supply voltage (V <sub>CC</sub> ) is low, or the carrier level is above the threshold. This output is off when disabled.
17	Enc Out	The digital output of the scrambler, which passes data from the CVSD encoder, or the T <sub>X</sub> Data register, or the T <sub>X</sub> 1010 Generator. Source selection is done through the $\mu$ P port.
18	V <sub>CC</sub>	Supply input for the audio sections, filters, and CVSD blocks. Allowable range is 2.7 to 5.5 V. Internally connected to Pins 27 and 37.
19	Enc In	The analog input to the CVSD encoder. Max. input level is 3.0 V <sub>pp</sub> .
20	T <sub>X</sub> Audio Out	Output of the transmit speech processing section.
21	Ground	Ground for the audio sections, filters, and CVSD blocks. Internally connected to Pins 30 and 40.
22	MCO	Output of the microphone amplifier, and input to the filters. This output has rail-to-rail capability.
23	MCI	Inverting input of the microphone amplifier. Gain and frequency response is set with external resistors and capacitors.
24	Enc Cap	This capacitor sets the time constant for the CVSD encoder. This pin is sensitive to leakage.
25	VAG	Analog ground for the audio section and the CVSD encoder and decoder.
26	Dec Cap	The capacitor sets the time constant for the CVSD decoder. This pin is sensitive to leakage.
27	V <sub>CC</sub>	Supply input for the audio sections, filters, and CVSD blocks. Allowable range is 2.7 to 5.5 V. Internally connected to Pins 18 and 37.
28, 29	PAO+, PAO-	Differential outputs of the power amplifier stage for driving an earpiece or hybrid network. The gain and frequency response are set with external resistors and capacitors.
30	Gnd	Ground for the audio sections, filters, and CVSD blocks. Internally connected to Pins 21 and 40.
31	PAI	Input to the power amplifier stage. This pin is a summing node.
32	R <sub>X</sub> Audio Output	Output of the receive speech processing section.
33	VB	The capacitor filters the internal 1.5 V reference voltage. If VB is adjusted, it may be monitored at this pin. Max. load current is 10 $\mu$ A.
34	R <sub>X</sub> Audio In	Input to the receive speech processing section.
35	Dec Out	The analog output of the CVSD decoder.
36	MP1	As an output, provides the recovered R <sub>X</sub> data, or the Data Detect output, or the data slicer output. Or it can be set to a high impedance input (600 k $\Omega$ ) for the carrier detect input signal. Selection is done through the $\mu$ P port. See Table 6.

**NOTE:** 1. All V<sub>CC</sub> pins must be within  $\pm 0.5$  V of each other.

# MC33410

## PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Description
37	V <sub>CC</sub>	Supply input for the audio sections, filters, and CVSD blocks. Allowable range is 2.7 to 5.5 V. Internally connected to Pins 18 and 27.
38	R <sub>X</sub> Digital Input	The digital stream from the RF receiver is applied to the data slicer at this pin. Minimum amplitude is 200 mVpp. Hysteresis ≈50 mV.
39	MP2	As an output, this pin provides the recovered clock from the Clock Recovery block. As an input, the CVSD decoder clock can be applied to this pin. Or this pin may be set to a disabled state. Selection is done through the $\mu$ P port. See Table 7. In Data Modem mode, the data to be transmitted is input to this pin.
40	Gnd	Ground for the audio sections, filters, and CVSD blocks. Internally connected to Pins 21 and 30.
41	LO2 Out	Buffered output of the 2nd LO frequency. A pullup resistor is required.
42	LO2 V <sub>CC</sub>	Supply pin for the 2nd LO. Allowable range is 2.7 to 5.5 V.
43, 45	LO2+, LO2-	A tank circuit is connected to these pins for the 2nd LO.
44	LO2 Ctl	The varactor control pin for the 2nd LO.
46	LO2 Gnd	Ground for the 2nd LO section.
47	LO2 PD	Phase detector charge pump output of the 2nd LO PLL.
48	LO2 Gnd	Ground for the 2nd LO section.

**NOTE:** 1. All V<sub>CC</sub> pins must be within  $\pm 0.5$  V of each other.

# MC33410

## FUNCTIONAL DESCRIPTION

Note: In the following descriptions, control bits in the MPU Serial Interface for the various functions will be identified by register number and bit number. For example, bit 3/19 indicates bit 19 of register 3. Bits 5/14–11 indicates register 5, bits 14 through 11. Please refer to Figure 1.

### Transmit Speech Processing Section

This section is made up of the externally adjustable microphone amplifier (Pins 22 to 23), internally adjustable gain stage, two low pass filters, and a mute switch.

The gain of the microphone amplifier is set with external resistors to receive the audio from the microphone (in the handset), or from the hybrid (in the base unit), or from any other audio source. The MCO output has rail-to-rail capability, and the dc bias level is at VB ( $\approx 1.5$  V).

The adjustable gain stage, referred to as the Remote Gain Adjust, provides 5 levels of gain in 4.0 dB increments. It is controlled with bits 6/15–11 as shown in Table 2.

**Table 1. Remote Gain Adjust**

Register 6	Gain
Bits 15–11	
00001	–8.0 dB
00010	–4.0 dB
00100	0 dB
01000	+4.0 dB
10000	+8.0 dB

Other combinations for the 5 bits are invalid.

The Low Pass Filter after the gain stage is a switched capacitor filter with a corner frequency at 5.0 kHz. The subsequent smoothing low pass filter has a corner frequency at 30 kHz, and is designed to filter out high frequency clock noise from the previously mentioned switched capacitor filter.

The mute switch at Pin 20 will mute a minimum of 60 dB. Bit 6/2 controls the mute.

### CVSD Encoder/Idle Channel/T<sub>X</sub> Data Register

The analog signals to be digitized are input at Pin 19 to the CVSD Encoder. The output of the encoder will be the digital equivalent of the audio, at the selected clock rate. Based on the reference frequency, bits 4/23–18 are used to set the 6 Bit Encoder Counter, in conjunction with the subsequent  $\pm 16$  divider, to set the CVSD Encoder frequency to 32, 50, or 64 kHz. Bits 3/16–15 will set the CVSD for proper operation at the selected frequency, according to Table 2.

**Table 2. CVSD Clock/Data Rates**

Register 3		Clock/Data Rate
Bit 16	Bit 15	
0	1	32 kHz
1	0	50 kHz
1	1	64 kHz

The Encoder's minimum step size can be selected using bits 2/22–21, according to Table 3.

**Table 3. Minimum Step Size**

Encoder Register 2 Bits 22, 21	Decoder Register 1 Bits 22, 21	Step Size
00	00	No minimum
01	01	1.4 mV
10	10	5.6 mV
11	11	22.4 mV

The T<sub>X</sub> 1010 Generator, when selected, provides an alternating “1–0” pattern (a square wave at half the CVSD clock rate) to the scrambler. This represents the lowest amplitude analog signal, and can be used when it is desired to send a quiet signal. Selection of this block can occur either automatically, or intentionally, as follows:

- The automatic selection occurs when the Idle Channel Detector senses the average audio signal at Pin 19 is below a threshold which is set with bits 5/17–15 (See Table 4). Bits 5/14–11 select a time delay for the automatic threshold detection to occur. The minimum delay is zero, with these bits set to 0000. Changing the bits provides delay in increments of 32 clock cycles (of the CVSD Encoder clock). The maximum delay is 480 clock cycles, (7.5 mS at 64 kHz). When the average audio signal at Pin 19 increases above the threshold, the T<sub>X</sub> 1010 Generator will be deselected with no delay. This automatic switchover feature can be disabled with bit 7/2. Bit 5/21 indicates when an idle channel condition has been detected. This output bit will be functional even when the idle channel detector is disabled with bit 7/2. Bit 5/18 will power down the Idle Channel Detect Circuit as a power saving measure.
- Bit 6/4 can be used to intentionally select the T<sub>X</sub> 1010 Generator at any time.

**Table 4. Idle Channel Detection Threshold**

Register 5		Register 5	
Bits 17–15	Threshold	Bits 17–15	Threshold
000	–50 dBV	100	–60 dBV
001	–52.5	101	–62.5
010	–55	110	–65
011	–57.5	111	–67.5

The T<sub>X</sub> Data Register is used for the transmission of data between the handset and base units. The procedure is as follows:

- At the receiving unit: The code word (16 or 24 bits, set with bit 7/11) identifying that a data transmission is occurring must be loaded into the T<sub>X</sub> Data Register (by loading register 8). This is used to detect when a code word is sent from the transmitting unit.
- At the transmitting unit: The same code word as above is loaded into register 8. It is automatically loaded into the T<sub>X</sub> Data Register.

## MC33410

- c. The data word (16 or 24 bits, set with bit 7/12) is then loaded into register 9.
- d. Upon loading register 9, the MC33410 automatically sends out (at Pin 17) the code word, followed by the data word, at the CVSD clock rate.

When the data word is completely sent out, the MC33410 will then return Pin 17 to its previous source of digital information (CVSD Encoder or  $T_x$  1010 Generator).

### Scrambler/Digital Output

The scrambler receives digital data from the CVSD Encoder, or the  $T_x$  1010 Generator, or the  $T_x$  Data Register,

to be output at Pin 17. The output level is 0 to  $V_{CC}$ . The scrambler can be bypassed with Bit 7/1.

The scrambler, better known as a randomizer, provides not only a level of communication security, but also helps ensure the digital output will not contain an abnormally long string of 1s or 0s which can adversely affect the CVSD Decoder operation, as well as the RF section. The scrambler is a maximal-length shift register sequence generator. The length of the shift register is selectable to one of eight values with bits 7/10–8 (the descrambler in the receiving unit must be set the same). Table 5 lists the polynomial associated with each tap selection.

Table 5. Scrambler/Descrambler Tap Selection

Tap No.	Register 7			Shift Register Length	Polynomial
	Bit 10	Bit 9	Bit 8		
0	0	0	0	2	$1 + z^{-1} + z^{-2}$
1	0	0	1	3	$1 + z^{-2} + z^{-3}$
2	0	1	0	4	$1 + z^{-3} + z^{-4}$
3	0	1	1	5	$1 + z^{-3} + z^{-5}$
4	1	0	0	6	$1 + z^{-5} + z^{-6}$
5	1	0	1	7	$1 + z^{-6} + z^{-7}$
6	1	1	0	9	$1 + z^{-5} + z^{-9}$
7	1	1	1	10	$1 + z^{-7} + z^{-10}$

### Data Slicer/Clock Recovery

The data slicer will receive the low level digital signal from the RF receiver section at Pin 38. The input signal to the data slicer must be  $>200$  mVpp. Hysteresis of 50 mV is internally provided. The output of the data slicer will be same waveform, but with an amplitude of 0 to  $V_{CC}$ , and can be observed at Pin 36 (MP1) if bits 7/5–4 are set to 10. The output can be inverted by setting bit 5/19 = 1.

The clock recovery block will generate a phase locked clock, equal to the CVSD data rate, from the incoming data, as long as the Encoder Counter (bits 4/23–18) is set for that data rate. The recovered clock can be observed at Pin 39 (MP2) if bits 7/7–6 are set to 00. The data from the clock recovery block can be observed at Pin 36 if bits 7/5–4 are set to 00. The clock recovery block may be bypassed by setting bit 7/0 to 1. With this setting the data slicer output will go directly to the descrambler, and the encoder clock will replace the Clock Recovery Clock.

Tables 6 and 7 summarize the options available at MP1 and MP2 (Pins 36 and 39).

Table 6. MP1 Options (Pin 36)

Register 7		Function
Bit 5	Bit 4	
0	0	Data from clock recovery block
0	1	Data Detect Output
1	0	Data Slicer Output
1	1	Hi-Z/ CD Input

Table 7. MP2 Options (Pin 39)

Register 7		Function
Bit 7	Bit 6	
0	0	Output recovered clock
0	1	Input CVSD Decoder clock
1	X	Disabled (Hi-Z)

When MP1 is set to a Hi-Z condition, the pin is an input for the CD (Carrier Detect) function, with an input impedance of 600 K $\Omega$ . See the section entitled Low Battery/Carrier Detect for an explanation of this function.

### Descrambler

The descrambler receives the scrambled data from the clock recovery block (or the data slicer if bit 7/0 = 1), and descrambles it to the original data as long as the selected taps are the same as those in the transmitting scrambler (see Table 5). The descrambler block is the same configuration as the scrambler, and is self-synchronizing. The descrambler can be bypassed with bit 7/1.

### Data Detect Register/Status Output/R<sub>X</sub> Data Register

The Data Detect register will continuously compare the descrambled data it receives with the 16 or 24-bit code word stored in the T<sub>X</sub> Data Register (loaded through register 8). Upon detecting a match, and after the code word passes through the shift register, the following (16 or 24-bit) data word will be stored into the R<sub>X</sub> Data Register, and then loaded into register 10 of the MPU Interface. At this time the Status output at Pin 13, and bit 5/22, will go high. The external microprocessor can then retrieve the data word by reading register 10, at which time the Status pin and bit will go low.

Upon detection of a code word as described above, the CVSD Decoder will be provided with 32, 40, or 48-bits of a 1010 pattern (idle channel) to minimize disturbances to the audio. After the data word is loaded into register 10, the CVSD Decoder resumes receiving data from the descrambler. The audio is therefore interrupted with a low level signal for a maximum of 48 clock cycles (0.75 mSec at 64 kHz).

The Data Detect register can be bypassed by setting bit 7/3 = 1.

### CVSD Decoder/Decoder Clock/Idle Channel

The CVSD Decoder will provide the analog equivalent, at Pin 35, of the digital data it receives from the descrambler, or from the 1010 generator (idle channel generator). There is a single pole filter at the Decoder output to reduce the clock noise normally present on a CVSD analog output. The CVSD Decoder is self synchronizing as long as the decoder clock matches the data rate, and the Decoder has been set with bits 3/16–15 according to Table 2.

The Decoder clock is provided from the Clock Recovery block by setting bits 7/7–6 to 00 or 1X. The clock is internally provided to the Decoder, and is available at Pin 39. Alternately, a Decoder clock can be provided from an

external source to Pin 39 by setting bit 7/7–6 to 01 (see Table 7).

The R<sub>X</sub> 1010 Generator provides an alternating 1–0 pattern (a square wave at half the CVSD clock rate) to the CVSD Decoder, resulting in the lowest amplitude analog signal at Pin 35. The 1010 Generator is automatically selected whenever data is detected and received by the Data Detection Circuit, as described above. Additionally, the 1010 Generator can be selected with bit 6/3 at any time.

The Decoder's minimum step size can be selected using bits 1/22–21, according to Table 3.

**Receive Audio Path**

The Receive Audio Path (Pins 34 to 32) consists of an anti–aliasing filter, a low pass filter, a gain adjust stage, and a mute switch.

Since the analog output of the CVSD Decoder (typically input at Pin 34) will contain noise at the CVSD clock rate, the anti–aliasing filter, with a corner frequency at 30 kHz, is provided to prevent aliasing of that clock noise with the subsequent switched capacitor filter.

The switched capacitor low pass filter is a 3 pole filter, with a corner frequency at 5.0 kHz. This is designed to remove the clock noise from the CVSD Decoder output signal, as well as provide bandwidth limiting in the audio range.

The gain stage provides 28.5 dB of gain adjustment in 19 steps (1.5 dB each), measured from Pin 34 to 32. Bits 6/10–6 are used to set the gain according to Table 8.

The mute switch at Pin 32, controlled by bit 6/1, will mute a minimum of 60 dB.

**Table 8. Receive Gain Adjustment**

Register 6	Gain	Register 6	Gain
Bits 10...6		Bits 10...6	
00110	–13.5 dB	10000	+1.5 dB
00111	–12.0 dB	10001	+3.0 dB
01000	–10.5 dB	10010	+4.5 dB
01001	–9.0 dB	10011	+6.0 dB
01010	–7.5 dB	10100	+7.5 dB
01011	–6.0 dB	10101	+9.0 dB
01100	–4.5 dB	10110	+10.5 dB
01101	–3.0 dB	10111	+12.0 dB
01110	–1.5 dB	11000	+13.5 dB
01111	0.0 dB	11001	+15.0 dB

**Power Amplifiers**

The power amplifiers (Pins 28, 29, 31) are designed to drive the earpiece in a handset, or the telephone line via a hybrid circuit in the base unit. Each output (PAO+ and PAO–) can source and sink 5 mA, and can swing 2.0 V<sub>pp</sub> each. The gain of the amplifiers is set with a feedback resistor from Pin 29 to 31, and an input resistor at Pin 31. The differential gain is 2x the resistor ratio. Capacitors can be used for frequency shaping. The pins' dc level is V<sub>B</sub> (≈1.5 V).

The Mute switch, controlled with bit 6/0, will provide 90 dB of muting with a 50 kΩ feedback resistor. The amount of muting will depend on the value of the feedback resistor.

**Reference Clock**

The reference clock provides the frequency basis for the three PLLs, the switched capacitor filters, and the CVSD

Encoder section. The source for the reference clock can be a crystal in the range of 4.0 to 18.25 MHz connected to Pins 14 & 15, or it can be an external source connected to F<sub>ref</sub> In (Pin 14). The reference frequency is directed to:

- A programmable 12–bit counter to provide the reference frequency for the three PLLs. The 12–bit counter is to be set such that, in conjunction with the programmable counters within each PLL, the proper frequencies can be produced by each VCO.
- A programmable 6–bit counter, followed by a ÷2 stage, to set the frequency for the switched capacitor filters to 256 kHz, or as close to that as possible.
- A programmable 6–bit counter which provides the 16x clock for the Clock Recovery block. This is followed by a ÷16 stage which provides the CVSD Encoder clock. This is followed by a ÷32 stage, and a programmable 4–bit counter which sets the delay for the Idle Channel Detect circuit.

**Transmit and Receive (LO1) PLL Sections**

The transmit and receive PLLs (Pins 6 to 9 and 1 to 4, respectively) are designed to be part of a 900 MHz system. In a typical application the Transmit PLL section will be set up to generate the transmit frequency, and the Receive PLL section will be set up to generate the LO1 frequency. The two sections are identical, and function independently. External requirements for each include a low pass filter, a 900 MHz VCO, and a 64/65 or 128/129 dual modulus prescaler.

The frequency output of the VCO is to be reduced by the dual modulus prescaler, and then input to the MC33410 (at Pin 2 or 8). That frequency is then further reduced by the programmable 13–bit counter (bits 1/19–7 or 2/19–7), and provided to one side of the Phase Detector, where it is compared with the PLL reference frequency. The output of the phase detector (at Pin 4 or 6) is a bi–directional charge pump which drives the VCO through the low pass filter. Bits 1/20 and 2/20 set the gain of each of the two charge pumps to either 100/2π μA/Radian or 400/2π μA/Radian. The polarity of the two phase detector outputs is set with bits 7/22 and 7/23. If the bit=0, the appropriate PLL is configured to operate with a non–inverting low pass filter/VCO combination. If the low pass filter/VCO combination is inverting, the polarity bit should be set to 1.

The 7–bit A and A' counters (bits 1/6–0 and 2/6–0) are to be set to drive the Modulus Control input of the 64/65 or 128/129 dual modulus prescalers. The Modulus Control outputs (Pins 1 and 9) can be set to either a voltage mode or a current mode with bit 7/13.

To calculate the settings of the N and A registers, the following procedure is used:

$$\frac{f_{VCO}}{f_{PLL}} = Nt \text{ (Nt must be an integer)} \quad \text{Equation 1}$$

$$\frac{Nt}{P} = N \quad \text{Equation 2}$$

$$A = \text{Remainder of Equation 2} \quad \text{Equation 3}$$

(decimal part of N x P)

where: f<sub>VCO</sub> = the VCO frequency  
 f<sub>PLL</sub> = the PLL Reference Frequency set within the MC33410  
 P = the smaller divisor of the dual modulus prescaler (64 for a 64/65 prescaler)

## MC33410

N = the whole number portion is the setting for the N (or N') counter within the MC33410

A = the setting for the A (or A') counter within the MC33410

For example, if the VCO is to provide 910 MHz, and the internal PLL reference frequency is 50 kHz, then the equations yield:

$$N_t = \frac{910 \times 10^6}{50 \times 10^3} = 18,200$$

$$N = \frac{18,200}{64} = 284.375$$

$$A = 0.375 \times 64 = 24$$

The N register setting is 284<sub>d</sub> (0 0001 0001 1100), and the A register setting is 24<sub>d</sub> (001 1000).

### 2nd LO (LO2)

This PLL is designed to be the 2nd Local Oscillator in a typical 900 MHz system, and is designed for frequencies up to 80 MHz. The VCO and varactor diodes are included, and are to be used with an external tank circuit (Pins 43 to 45).

Bits 7/20–18 are used to select an internal capacitor, with a value in the range of 0 to 7.6 pF, to parallel the varactor diodes and the tank's external capacitor. This permits a certain amount of fine tuning of the oscillator's performance. See Table 9.

A buffered output is provided to drive, e.g., a mixer. The frequency is set with the programmable 14-bit counter (bits 3/13–0) in conjunction with the PLL reference frequency. For example, if the reference frequency is 50 kHz, and the 2nd LO frequency is to be 63.3 MHz, the 14-bit counter needs to be set to 1266<sub>d</sub> (00 0100 1111 0010). The output level is dependent on the value of the impedance at Pin 41, partly determined by the external pullup resistor.

The output of the phase detector is a bi-directional charge pump which drives the varactor diodes through an external low pass filter. Bit 3/14 sets the gain of the charge pump to either 100/2π μA/Radian or 400/2π μA/Radian. Bit 7/21 sets its polarity – if 0, the PLL is configured to operate with a non-inverting low pass filter/VCO combination. If the low pass filter/VCO combination is inverting, the polarity bit should be set to 1.

**Table 9. LO2 Capacitor Selection**

Register 7 Bits 20–18	Capacitor Value	Register 7 Bits 20–18	Capacitor Value
000	0 pF	100	4.3 pF
001	1.1 pF	101	5.4 pF
010	2.2 pF	110	6.5 pF
011	3.3 pF	111	7.6 pF

### VB Reference Voltage

The VB voltage (≈1.5 V) is available at Pin 33. It will have a production tolerance of ±6%, and can be adjusted over a ±9% range using bits 3/20–17. The adjustment steps will be ≈1.2% each. VB can be used to bias external circuitry, as long as the load current on this pin does not exceed 10 μA.

### Low Battery/Carrier Detect

This circuit will provide an indication of either Low Battery voltage, or a low carrier signal applied to Pin 36 (MP1) from an RSSI circuit. The desired mode is selected with bit 6/5.

#### A) Low Battery Mode (Bit 6/5 = 0)

The supply voltage at Pin 18 is applied to the comparator through an internal resistor divider, and is compared to the internal reference VB (≈1.5 V). The comparator has ≈15 mV of hysteresis, measured at V<sub>CC</sub>. The resistor divider is adjustable using bits 3/23–21. The Low Battery threshold voltage will then be equal to the VB voltage multiplied by the factor listed in Table 10. For example, if VB = 1.5 V, and bits 3/23–21 = 011, the threshold will be 3.21 V.

#### B) Carrier Detect Mode (Bit 6/5 = 1)

Pin 36 (MP1) must be set to the Hi-Z/CD Input mode by setting bits 7/5–4 to 11. MP1 will then be an input with an input impedance of ≈600 kΩ, referenced to VB. An analog signal applied to MP1 will be applied to the comparator through an internal adjustable gain stage (adjustable using bits 3/23–21), and is compared to the internal reference VB. The comparator has ≈18.0 mV of hysteresis, measured at Pin 36. The threshold voltage will then be equal to the VB voltage multiplied by the factor listed in Table 10. For example, if VB = 1.5 V, and bits 3/23–21 = 011, the threshold will be 0.576 V.

**Table 10. LB/CD Threshold Adjustment Factor**

Register 3 Bits 23–21	Low Battery Mode	Carrier Detect Mode
000	1.96	0.574
001	2.02	0.524
010	2.08	0.453
011	2.14	0.384
100	2.19	0.314
101	2.25	0.247
110	2.30	0.177
111	2.37	0.110

The comparator output is at bit 5/23, and at Pin 16 (open collector output). The outputs are high if the monitored V<sub>CC</sub> voltage is above the threshold, or if the Carrier signal is below the threshold. Pin 16 requires an external pullup resistor. When this circuit is disabled (bit 5/10 = 1), bit 5/23 and Pin 16 will be high.

### MPU Serial Interface

The MPU Serial Interface is a 3-wire interface, consisting of a Clock line, an Enable line, and a bi-directional Data line. The interface is always active, i.e. it cannot be powered down as all other sections of the MC33410 are disabled and enabled through this interface.

The clock must be supplied to the MC33410 at Pin 11 to write or read data, and can be any frequency up to 2.0 MHz. The clock need not be present when data is not being transferred. The Enable line must be low when data is not being transferred.

Internally there are 10 data registers, 24 bits each, addressed with four bits ranging from \$1 to \$A. Register 10, and bits 23–21 of register 5 contain data to be read out by the microprocessor, while all other register bits are to be written to by the microprocessor. The contents of the 10 registers can be read out at any time. All bits are written in, or read out, on the clock's positive transition. The write and read operations are as follows:

a) Write Operation:

## MC33410

To write data to the MC33410, the following sequence is required (see Figure 3):

5. The Enable line is taken high.
6. Five bits are entered:
  - The first bit must be a 0 to indicate a Write operation.
  - The next four bits identify the register address (0001–1010). The MSB is entered first.
7. After the 5th clock pulse is low, the Enable line is taken low. At this transition, the address is latched in and decoded.
8. The Enable line is maintained low while the data bits are clocked in. The MSB is entered first, and the LSB last. If 24 bits are written to a register which has less than 24 active bits (e.g., register 6), the unassigned bits are to be 0.

9. After the last bit is entered, the Enable line is to be taken high and then low. The falling edge of this pulse latches in the just entered data. The clock line can be at a logic high or low, but must not transition in either direction during this Enable pulse.

10. The Enable line must then be kept low until the next communication.

Note: If less than 24 bits are to be written to a data register, it is not necessary to enter the full 24 bits, as long as they are all lower order bits. For example, if bits 0–6 of a register are to be updated, they can be entered as 7 bits with 7 clock cycles in step 4 above. However, if this procedure is used, a minimum of 4 bits, with 4 clock pulses, must be entered.

Figure 3. Writing Data to the MC33410

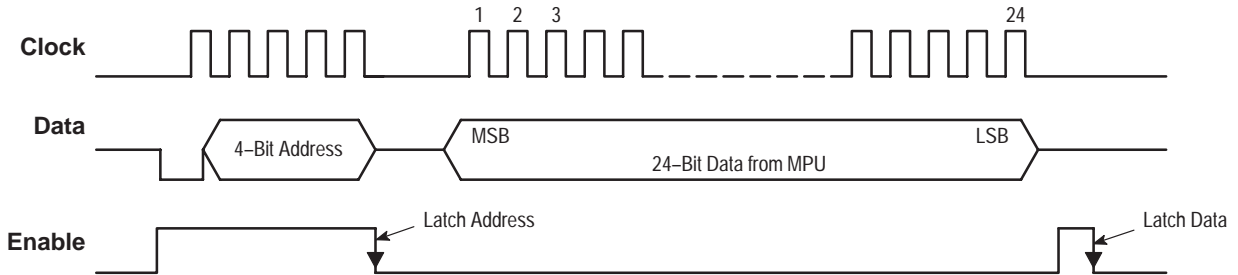

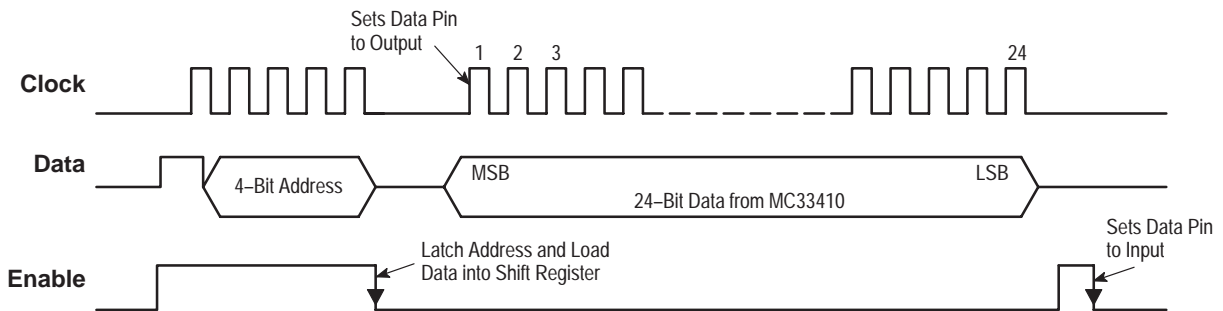

Figure 4. Reading Data from the MC33410

### b) Read Operation:

To read the output bits (bits 5/23–21, or all of register 10), or the contents of any register, the following sequence is required (see Figure 4):

1. The Enable line is taken high.
2. Five bits are entered:
  - The first bit must be a 1 to indicate a Read operation.
  - The next four bits identify the register address (0001–1010). The MSB is entered first.
3. After the 5th clock is taken low, the Enable line is taken low. At this transition, the address is latched in and decoded, and the contents of the selected register is loaded into the 24-bit output shift register. At this point, the Data line (Pin 12) is still an input.
4. While maintaining the Enable line low, the data is read out. The first clock rising edge will change the Data line to an output, and the MSB will be present on this line.
5. The full contents of the register are then read out (MSB first, LSB last) with a total of 24 clock rising edges, including the one in step 4 above. It is recommended that the MPU read the bits at the clock's falling edge. If only bit 23, 22, or 21 of register 5 are to be read, this can be done with one, two, or three clock rising edges, respectively.

6. After the last clock pulse, the Enable line is to be taken high and then low. The falling edge of this pulse returns the Data pin to be an input. The clock line can be at a logic high or low, but must not transition in either direction during this Enable pulse.

7. The Enable line must then be kept low until the next communication.

### Data Modem Mode

For applications where the MC33410 is to be used in a 900 MHz wireless system for transmitting data only (non-voice), a mode can be set which bypasses the speech digitizing sections. The resulting configuration makes use of those sections associated with data only, i.e., the scrambler, descrambler, and clock recovery section. Also functional are the three PLLs, the audio receive path (Pins 34 to 28), the transmit audio path (Pins 23 to 20), and the Low Battery circuit (but not the Carrier Detect mode).

In this mode, the MC33410 will provide the transmit data clock from the crystal, in conjunction with the internal 6-bit counter (bits 4/23–18) and the +16 block associated with that counter. The transmit data clock is available at Pin 13, and can be used to synchronize the external data source. The  $T_X$

## MC33410

data is input at Pin 39, passes through the scrambler, and outputs at Pin 17.

The demodulated data from the RF receiver is input at Pin 38, and is applied to the data slicer, and the clock recovery block. The recovered clock is output at Pin 12. The data passes through the descrambler, and is output at Pin 36.

Figure 5 is a diagram of the data paths through the MC33410.

The procedure for entering the Data Modem mode is in Table 11:

The above sequence is not critical, except that the last two steps must be the setting of bit 5/20, and writing to register 11. Writing to register 11 is shown in Figure 6.

**Table 11. Entering Data Modem Mode**

Function	Bits	Bit Value
Set $T_X$ Clock to desired frequency $T_X \text{ Clk} = F_{\text{Crystal}} / (16 \times \text{Counter})$ .	4/23 – 18	As Desired
Set Scrambler & Descrambler tap setting (Bit 7/1 = 0).	7/10 – 8	As Desired
Bypass Data Detect.	7/3	1
Set MP1 to Data Detect Output.	7/5 – 4	01
Set Test Mode bits to connect Encode Clock to Status (Pin 13).	7/17 – 15	110
Set Data Modem Mode (MP2 to scrambler Input).	5/20	1
Write to Register 11 as shown in Figure 6 to configure Pin 12.	N/A	N/A

**Figure 5. Data Modem Mode Configuration**

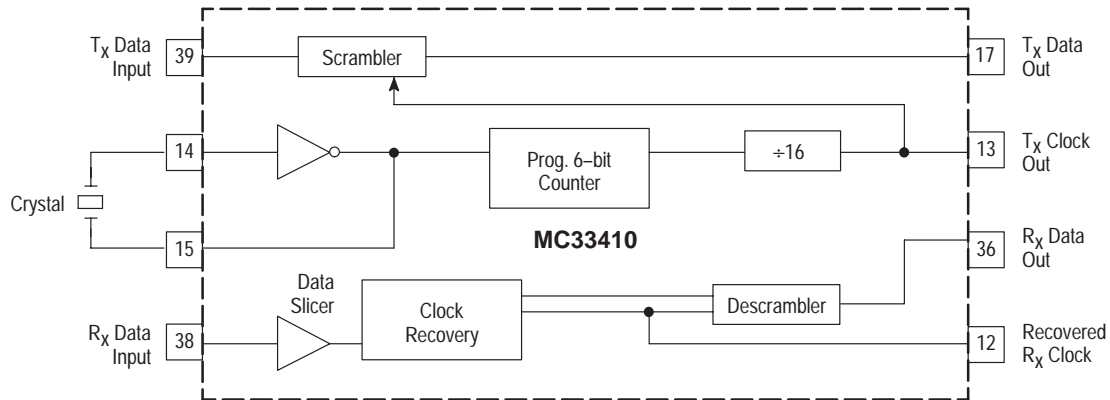

Figure 6. Entering/Exiting Data Modem Mode

After address 11 is clocked in, the Enable falling edge will cause Pin 12 (Data) to switch to an output, providing the recovered clock. The microprocessor's data pin must be changed to an input prior to this falling edge. This sequence is effective only if bit 5/20 is set to a 1.

During the time that recovered clock is available at Pin 12, the microprocessor port is unavailable for any control functions.

To exit the Data Modem mode, the Enable line is to be taken high and low (the clock is to be stable during this active high pulse). The falling edge will set Pin 12 to be an input, allowing normal use of the microprocessor port. The next step is to set bit 5/20 to a 0. Other register bits can then be set as needed.

To prevent inadvertent incorrect operation of the microprocessor port, bit 5/20 must always be set to 0 when the Data Modem mode is not in use.

#### Power Supply/Power Saving Modes

The power supply voltage, applied to all  $V_{CC}$  pins, can range from 2.7 to 5.5 V. All  $V_{CC}$  pins must be within  $\pm 0.5$  V of each other, and each must be bypassed. It is recommended a ground plane be used, and all leads to the MC33410 be as short and direct as possible. The supply and ground pins are distributed as follows:

1. Pins 18, 27 and 37 are internally connected together, and provide power to the audio amplifiers, filters, CVSD encoder and decoder, and the low frequency (CVSD rate) logic circuits. Pins 21, 30 and 40 are the ground pins for these sections.
2. Pin 3 provides power to the  $R_X$  PLL section. Pin 5 is the ground pin.
3. Pin 7 provides power to the  $T_X$  PLL section, and the MPU interface. Pin 5 is the ground pin.
4. Pin 42 provides power to the 2nd LO section. Pins 46 and 48 are the ground pins.

To conserve power, various sections can be individually disabled, using bits 5/10–0 (setting a bit to 1 disables the section).

1. Reference Oscillator Disable (bit 5/0) – The reference oscillator at Pins 14 and 15 is disabled, thereby denying a clock to the three PLLs, the CVSD Encoder, and the switched capacitor filters.
2.  $T_X$  PLL Disable (bit 5/1) – The 13-bit and 7-bit counters, input buffer, phase detector, and modulus control blocks are disabled. The charge pump output at Pin 6 will be in a Hi-Z state.
3.  $R_X$  PLL Disable (bit 5/2) – The 13-bit and 7-bit counters, input buffer, phase detector, and modulus control blocks are disabled. The charge pump output at Pin 4 will be in a Hi-Z state.
4. LO2 PLL Disable (bit 5/3) – The VCO, 14-bit counter, output buffer, and phase detector are disabled. The charge pump output at Pin 47 will be in a Hi-Z state.
5.  $R_X$  Data Path Disable (bit 5/4) – The data slicer, clock recovery block, descrambler, data detect register, and the status output circuit are disabled. The state of the status line (Pin 13 and bit 5/22) will not change upon disabling this section.
6. CVSD Decoder Disable (bit 5/5) – The CVSD Decoder and the  $R_X$  1010 Generator are disabled.
7.  $R_X$  Audio Path Disable (bit 5/6) – The anti-aliasing filter, low pass filter, and variable gain stage are disabled.
8. Power Amplifier Disable (bit 5/7) – The two power amplifiers are disabled. Their outputs will go to a Hi-Z state.
9.  $T_X$  Audio Path Disable (bit 5/8) – Disables the microphone amplifier, low pass filter, and smoothing filter.
10. CVSD Encoder Disable (bit 5/9) – The CVSD Encoder, Idle Channel detect circuit, the  $T_X$  1010 Generator, the  $T_X$  Data register, and the scrambler are disabled.
11. Low Battery/Carrier Detect Disable (bit 5/10) – The LB/CD circuit is disabled. The output, at bit 5/23 and Pin 16 will be at a logic high.
12. Idle Channel Detect Disable (bit 5/18) – Powers down the Idle Channel Detect circuit.

Note: The 12-bit reference counter is disabled if the three PLLs are disabled (bits 5/1–3 = 1).

# MC33410

**Table 12. Control Bit Listing (By Register Number)**

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
1 (23 bits total)	6 – 0	1000000	Sets the 7-bit T <sub>X</sub> A counter for the T <sub>X</sub> PLL.
	19 – 7	10...0	Sets the 13-bit T <sub>X</sub> N counter for the T <sub>X</sub> PLL.
	20	0	Sets the T <sub>X</sub> phase detector charge pump output current. 0 = ±100 μA, and 1 = ±400 μA.
	22, 21	00	Sets CVSD Decoder minimum step size per Table 3.
2 (23 bits total)	6 – 0	1000000	Sets the 7-bit R <sub>X</sub> A' counter for the R <sub>X</sub> PLL.
	19 – 7	10...0	Sets the 13-bit R <sub>X</sub> N' counter for the R <sub>X</sub> PLL.
	20	0	Sets the R <sub>X</sub> phase detector charge pump output current. 0 = ±100 μA, and 1 = ±400 μA.
	22, 21	00	Sets CVSD Encoder minimum step size per Table 3.
3 (24 bits total)	13 – 0	10...0	Sets the 14-bit counter for the 2nd LO.
	14	0	Sets the LO2 phase detector charge pump output current. 0 = ±100 μA, and 1 = ±400 μA.
	16 – 15	11	Set the CVSD encoder/decoder for the selected clock rate. (Table 2)
	20 – 17	0111	Adjusts the VB reference voltage (≈1.5 V) to improve low battery detection accuracy. Total adjustment range is ≈±9%.
	23 – 21	011	Selects the threshold for Low Battery Detection or Carrier Signal Detection. See Table 10.
4 (24 bits total)	11 – 0	\$800	Sets the 12-bit counter for the PLL Reference Clock.
	17 – 12	100000	Sets the 6-bit counter for the Switched Capacitor Filter clock.
	23 – 18	100000	Sets the 6-bit counter to set the CVSD Encoder clock rate.
5 (24 bits total)	0	0	Power down the Reference Oscillator
	1	0	Power down the T <sub>X</sub> PLL.
	2	0	Power down the R <sub>X</sub> PLL.
	3	0	Power down the LO2 PLL.
	4	0	Power down the R <sub>X</sub> Data Path. Includes Data Slicer, Clock Recovery, Descrambler, Data Detect, and Status circuits.
	5	0	Power down the CVSD Decoder.
	6	0	Power down the R <sub>X</sub> Audio path (Pin 32 to 30). Includes AALPF, LPF, and Gain Adjust circuits.
	7	0	Power down the Power Amplifiers (Pins 27, 28)
	8	0	Power down the T <sub>X</sub> Audio Path (Pin 25 to 22). Includes micro-phone amplifier, LPF, and Smoothing LPF circuits.
	9	0	Power down the CVSD Encoder, Idle Channel Detector, 1010 Generator, T <sub>X</sub> Data Register, and Scrambler circuits.
	10	0	Power down the Low Battery/Carrier Detect Circuit.
	14 – 11	0111	Sets the 4-bit counter to set the response delay for the idle channel detect circuit.
	17 – 15	100	Sets the idle channel detect threshold level. See Table 4.
	18	0	Power down the Idle Channel Detect Circuit.
	19	0	Inverts the Data Slicer output.
20	0	Sets the Data Modem mode of operation.	
21	N/A	Indicates an idle channel condition has been detected (Output). This output is unaffected by bit 7/2.	
22	N/A	The Status Output (same as Pin 13) is read out from this bit.	
23	N/A	The output of the Low Battery/Carrier Detect Circuit is read from this bit.	

# MC33410

**Table 12. Control Bit Listing (By Register Number) (continued)**

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
6 (16 bits total)	0	0	Mutes the power amplifiers (Pins 27 to 29).
	1	0	Mutes the receive speech processing path (Pin 30).
	2	0	Mutes the transmit speech processing path (Pin 22).
	3	0	Selects the R <sub>X</sub> 1010 Generator to the CVSD decoder.
	4	0	Selects the T <sub>X</sub> 1010 Generator to the scrambler.
	5	0	Sets Carrier Detect Mode vs. Low Battery mode.
	10 – 6	01111	Provides 19 steps, 1.5 dB each (28.5 dB range), of gain adjust in the receive speech audio path (Pins 32 to 30). See Table 8.
	15 – 11	00100	Provides 4 steps of 4.0 dB each, for the remote gain adjust in the transmit speech audio path (Pins 23 to 20).
7 (24 bits total)	0	0	Bypass the Clock Recovery Block (Data slicer output goes directly to the descrambler).
	1	0	Bypass the scrambler and descrambler.
	2	0	Disables the automatic idle channel detect at the CVSD encoder. Bit 5/21 is still active.
	3	0	Bypass the Data Detect block (Descrambler output goes directly to the CVSD Decoder).
	5 – 4	00	Determines the function for Pin 36 (MP1). See Table 6.
	7 – 6	00	Determines the function for Pin 39 (MP2). See Table 7.
	10 – 8	010	Selects one of 8 programmable taps in the scrambler and descrambler. See Table 5.
	11	1	Sets the code word size to be sent out via the T <sub>X</sub> Data Register to 24 bits. If this bit is 0, the code word size is 16 bits.
	12	1	Sets the data word size to be sent out via the T <sub>X</sub> Data Register to 24 bits. If this bit is 0, the data word size is 16 bits.
	13	0	Sets the FT <sub>X</sub> MC and FR <sub>X</sub> MC output level to be from ground to V <sub>CC</sub> . If this bit is 0, the output level is ±100 μA.
	14	0	Disables the CVSD charge compensation circuit.
	17 – 15	000	Test modes for production testing only.
	20 – 18	000	Selects the value of the internal capacitor between Pins 43 to 45, to fine tune the LO2 tank circuit. See Table 9.
	21	0	Sets the polarity of the 2nd LO phase detector charge pump output for an inverting low pass filter/VCO combination.
22	0	Sets the polarity of the R <sub>X</sub> phase detector charge pump output for an inverting low pass filter/VCO combination.	
23	0	Sets the polarity of the T <sub>X</sub> phase detector charge pump output for an inverting low pass filter/VCO combination.	
8	23 – 0	\$000000	Code word for the T <sub>X</sub> Data Register is entered into this register.
9	23 – 0	\$000000	Data word for the T <sub>X</sub> Data Register is entered into this register.
10	23 – 0	\$000000	The data word received into the R <sub>X</sub> Data Register is read out via the μP port from this register.

# MC33410

**Table 13. Control Bit Listing (By Function)**

## PLL Controls

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
1	6 – 0	1000000	Sets the 7-bit $T_X$ A counter for the $T_X$ PLL.
1	19 – 7	10...0	Sets the 13-bit $T_X$ N counter for the $T_X$ PLL.
2	6 – 0	1000000	Sets the 7-bit $R_X$ A' counter for the $R_X$ PLL.
2	19 – 7	10...0	Sets the 13-bit $R_X$ N' counter for the $R_X$ PLL.
3	13 – 0	10...0	Sets the 14-bit counter for the 2nd LO.
4	11 – 0	\$800	Sets the 12-bit counter for the PLL Reference Clock.
7	13	0	Sets the $FT_X$ MC and $FR_X$ MC output level to be from ground to $V_{CC}$ . If this bit is 0, the output level is $\pm 100 \mu A$ .

## PLL Phase Detectors

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
1	20	0	Sets the $T_X$ phase detector charge pump output current. 0 = $\pm 100 \mu A$ , and 1 = $\pm 400 \mu A$ .
2	20	0	Sets the $R_X$ phase detector charge pump output current. 0 = $\pm 100 \mu A$ , and 1 = $\pm 400 \mu A$ .
3	14	0	Sets the LO2 phase detector charge pump output current. 0 = $\pm 100 \mu A$ , and 1 = $\pm 400 \mu A$ .
7	20 – 18	000	Selects the value of the internal capacitor between Pins 43 to 45, to fine tune the LO2 tank circuit. See Table 9.
7	21	0	Sets the polarity of the 2nd LO phase detector charge pump output for an inverting low pass filter/VCO combination.
7	22	0	Sets the polarity of the $R_X$ phase detector charge pump output for an inverting low pass filter/VCO combination.
7	23	0	Sets the polarity of the $T_X$ phase detector charge pump output for an inverting low pass filter/VCO combination.

## CVSD Controls

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
1	22, 21	00	Sets CVSD Decoder minimum step size per Table 3.
2	22, 21	00	Sets CVSD Encoder minimum step size per Table 3.
3	16 – 15	11	Set the CVSD encoder/decoder for the selected clock rate. (Table 2)
4	23 – 18	100000	Sets the 6-bit counter to set the CVSD Encoder clock rate.
6	3	0	Selects the $R_X$ 1010 Generator to the CVSD decoder.
6	4	0	Selects the $T_X$ 1010 Generator to the scrambler.
7	14	0	Disables the CVSD charge compensation circuit, which affects idle channel performance.

## Idle Channel Detector

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
5	14 – 11	0111	Sets the 4-bit idle channel counter to set the response delay for the idle channel detect circuit.
5	17 – 15	100	Sets the idle channel detect threshold level. See Table 4.
5	21	N/A	Indicates an idle channel condition has been detected (Output). This output is unaffected by bit 7/2.
7	2	0	Disables the automatic idle channel detect at the CVSD encoder. Bit 5/21 is still active.

# MC33410

**Table 13. Control Bit Listing (By Function) (continued)**

## Data Transmission/Reception

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
5	19	0	Inverts Data Slicer output.
5	20	0	Sets Data Modem mode.
5	22	N/A	The Status Output (same as Pin 13) is read out from this bit. A logic 1 indicates the Data Detect register has detected a code word.
7	0	0	Bypass the Clock Recovery Block (Data slicer output goes directly to the descrambler).
7	3	0	Bypass the Data Detect block (Descrambler output goes directly to the CVSD Decoder).
7	11	1	Sets the code word size to be sent out via the T <sub>X</sub> Data Register to 24 bits. If this bit is 0, the code word size is 16 bits.
7	12	1	Sets the data word size to be sent out via the T <sub>X</sub> Data Register to 24 bits. If this bit is 0, the data word size is 16 bits.
8	23 – 0	\$000000	Code word for the T <sub>X</sub> Data Register is entered into this register.
9	23 – 0	\$000000	Data word for the T <sub>X</sub> Data Register is entered into this register.
10	23 – 0	\$000000	The data word received into the R <sub>X</sub> Data Register is read out via the μP port from this register.

## Scrambler/Descrambler

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
7	1	0	Bypass the scrambler and descrambler.
7	10 – 8	010	Selects one of 8 programmable taps in the scrambler and descrambler. See Table 5.

## Multi Purpose Pin Control

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
7	5 – 4	00	Determines the function for Pin 36 (MP1). See Table 6.
7	7 – 6	00	Determines the function for Pin 39 (MP2). See Table 7.

## Audio Paths

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
4	17 – 12	100000	Sets the 6-bit counter for the Switched Capacitor Filter clock.
6	0	0	Mutes the power amplifiers (Pins 27 to 29).
6	1	0	Mutes the receive speech processing path (Pin 30).
6	2	0	Mutes the transmit speech processing path (Pin 22).
6	10 – 6	01111	Provides 19 steps, 1.5 dB each (28.5 dB range), of gain adjust in the receive speech audio path (Pins 32 to 30). See Table 8.
6	15 – 11	00100	Provides 4 steps of 4.0 dB each, of gain adjust in the transmit speech audio path (Pins 23 to 20).

## Low Battery/Carrier Detection

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
3	20 – 17	0111	Adjusts the VB reference voltage ( $\approx 1.5$ V) to improve low battery detection accuracy. Total adjustment range is $\approx \pm 9\%$ .
3	23 – 21	011	Selects the threshold for Low Battery Detection or Carrier Signal Detection. See Table 10.
5	23	N/A	The output of the Low Battery/Carrier Detect Circuit is read from this bit.
6	5	0	Sets Carrier Detect Mode vs. Low Battery Mode

# MC33410

Table 13. Control Bit Listing (By Function) (continued)

## Power Down Control

Register	Bit No.	Power Up Default	Function (when bit = 1 if appropriate)
5	0	0	Power down the Reference Oscillator
5	1	0	Power down the T <sub>X</sub> PLL.
5	2	0	Power down the R <sub>X</sub> PLL.
5	3	0	Power down the LO2 PLL.
5	4	0	Power down the R <sub>X</sub> Data Path. Includes Data Slicer, Clock Recovery, Descrambler, Data Detect, and Status circuits.
5	5	0	Power down the CVSD Decoder.
5	6	0	Power down the R <sub>X</sub> Audio path (Pin 32 to 30). Includes AALPF, LPF, and Gain Adjust circuits.
5	7	0	Power down the Power Amplifiers (Pins 27, 28)
5	8	0	Power down the T <sub>X</sub> Audio Path (Pin 25 to 22). Includes micro-phone amplifier, LPF, and Smoothing LPF circuits.
5	9	0	Power down the CVSD Encoder, Idle Channel Detector, 1010 Generator, T <sub>X</sub> Data Register, and Scrambler circuits.
5	10	0	Power down the Low Battery/Carrier Detect Circuit.
5	18	0	Power down the Idle Channel Detection Circuit.

## 900 MHz Analog Cordless Phone Baseband with Compander

The MC33411 900 MHz Analog Cordless Phone Baseband system is designed to fit the requirements of a 900 MHz analog cordless telephone system. Included are three PLLs (Phase-Locked Loops). Two are intended for use with external VCOs and 64/65 or 128/129 dual modulus prescalers, and can control the transmit and receive (LO1) frequencies for 900 MHz communication. The third PLL is configured as the 2nd local oscillator (LO2), and is functional to 80 MHz. Also included are muting, audio gain adjust (internal and external), low battery/carrier detect, and a wide range for the PLL reference frequency. The power supply range is 2.7 to 5.5 V. "A" version devices have programmable MCU clock out and reference oscillator disable functions, whereas these functions are always enabled for "B" version devices.

- Complete Expander/Compressor for Superior Noise Rejection
- Two PLLs and a LO Suitable for a 900 MHz System
- Minimal External Components
- Transmit Path Includes Adjustable Gain Amplifier, Filters, Mute, Compressor with Bypass and Limiter
- Receive Path Contains Data Slicer, Adjustable Gain Amplifier, Sidetone Attenuator, Filters, Expander with Bypass, Mute, Volume Control and Power Amplifier
- Dual A/Ds are Provided to Monitor RSSI and V<sub>CC</sub>
- Independent Power Amplifier with Differential Outputs and Mute
- Selectable Frequency for Switched Capacitor Filters, PLLs and the LO
- Reference Frequency Source can be a Crystal or System Clock
- Serial  $\mu$ P Port to Control Gain, Mute, Frequency Selection, Phase Detector Gain, Power Down Modes, Low Battery Detect and Others
- Power Supply Range: 2.7 to 5.5 V
- Power Down Modes for Power Conservation

## MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Power Supply Voltage	$V_{CC}$	-0.5 to 6.0	V
Junction Temperature	$T_J$	-6.5 to 150	°C
Maximum Power Dissipation	$P_D$	150	mW

- NOTES:** 1. Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Recommended Operating Conditions, Electrical Characteristics tables or Pin Descriptions section.  
2. Meets Human Body Model (HBM)  $\leq 2000$  V and Machine Model (MM)  $\leq 200$  V. ESD data available upon request.

## RECOMMENDED OPERATING CONDITIONS

Characteristic	Symbol	Min	Typ	Max	Unit
Supply Voltage	$V_{CC}$	2.7	3.6	5.5	Vdc
Operating Ambient Temperature	$T_A$	-20	-	70	°C
Input Voltage Low (Data, CLK, EN)	$V_{il}$	-	-	0.3	V
Input Voltage High (Data, CLK, EN)	$V_{ih}$	Tx PLL $V_{CC} - 0.3$	-	-	V
Frequency Range ( $F_{ref}$ in)	$F_{range}$	4.0	-	18.25	MHz
Bandgap Reference Voltage	$V_B$	-	1.5	-	V

## DC ELECTRICAL CHARACTERISTICS ( $V_{CC} = 3.6$ V, $T_A = 25^\circ\text{C}$ , unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
Static Current					
Active Mode (R5/8 to 0 = 0; R6/7 = 0)	ACT $I_{CC}$	-	15	20	mA
Receive Mode (R5/8, 7, 3, 2, 0 = 0; R6/7 = 0; R5/6,5,4,1 = 1)	Rx $I_{CC}$	-	10	13	mA
Standby Mode (R5/0 = 0; R6/7 = 0; R5/8 to 1 = 1)	STD $I_{CC}$	-	500	1500	$\mu\text{A}$
Inactive Mode, A only (R5/8 to 0 = 1; R6/7 = 1)	INA $I_{CC}$	-	10	15	$\mu\text{A}$
Data Slicer Only	DS $I_{CC}$	-	100	-	$\mu\text{A}$
RSSI/Batt A/D Only	AD $I_{CC}$	-	70	-	$\mu\text{A}$
Tx Audio Only	TxA $I_{CC}$	-	1.4	-	mA
Rx Audio Only	RxA $I_{CC}$	-	1.4	-	mA
PA Only	PA $I_{CC}$	-	1.0	-	mA
2nd LO/ $F_{ref}$ Only	2LO $I_{CC}$	-	6.0	-	mA
Rx PLL/ $F_{ref}$ Only	RxPLL $I_{CC}$	-	1.0	-	mA
Tx PLL/ $F_{ref}$ Only	TxPLL $I_{CC}$	-	1.0	-	mA
Ref Osc Only, "A" version only	ROSC $I_{CC}$	-	500	-	$\mu\text{A}$
Reference Voltage, Unadjusted	$V_B$	1.38	1.5	1.62	V

## ELECTRICAL CHARACTERISTICS ( $V_{CC} = 3.6$ V, $V_B = 1.5$ V, $T_A = 25^\circ\text{C}$ , Active Mode, Rx Gain = 01111, Vol Adj = 0111, $f_{in} = 1.0$ kHz, unless otherwise noted.)

## PIN FUNCTION DESCRIPTION

Pin	Symbol/Type	Description	Description
1	FRx MC (Output)		Modulus Control Output for the Rx PLL section. Can be set to output in current mode or voltage mode, selectable with bit 3/16.
2	FRx (Input)		Receives the signal from the external 64/65 or 128/129 prescaler. DC bias is at 1.3 V.

**NOTE:** 1. All  $V_{CC}$  pins must be within  $\pm 0.5\text{ V}$  of each other.

# MC33411A/B

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol/Type	Description	Description
3	Rx PLL V <sub>CC</sub> (Input)		Supply pin for the Rx PLL section. Allowable range is 2.7 to 5.5 V and must be within 0.5 V of all other V <sub>CC</sub> pins. Good bypassing is required and isolation with a 10 Ω resistor is recommended.
4	Rx PD (Output)		Rx Phase Detector Output. The output either sources or sinks current, or neither, depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the PLL reference frequency are present. Output current is either ±100 μA or ±400 μA, selectable with bit 2/20.
5	PLL Gnd		Ground pin for the PLL section. A direct connection to a ground plane is strongly recommended.
6	Tx PD (Output)	Same as Pin 4, except powered from Tx PLL V <sub>CC</sub> .	Tx Phase Detector Output. Description same as for Pin 4, except bit 1/20 controls the current level.
7	Tx PLL V <sub>CC</sub> (Input)		Supply pin for the Tx PLL section, MCU Serial Interface, MCU Clock Counter, and the Reference Oscillator. Allowable range is 2.7 to 5.5 V and must be within 0.5 V of all other V <sub>CC</sub> pins. Good bypassing is required and isolation with a 10 Ω resistor is recommended.
8	FTx (Input)	Same as Pin 2.	Receives the signal from the external 64/65 or 128/129 prescaler. DC bias is at 1.5 V.
9	FTx MC (Output)		Modulus Control Output for the Tx PLL section. Can be set to output in a current mode or a voltage mode, selectable with bit 3/16.

**NOTE:** 1. All V<sub>CC</sub> pins must be within ±0.5 V of each other.

# MC33411A/B

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol/Type	Description	Description
10	EN (Input)		Enable Input for the MCU Interface section. Hysteresis threshold is within 0.5 V of ground and $V_{CC}$ . See text for proper waveform required at this pin.
11	CLK (Input)	Same as Pin 10.	Clock Input for the MCU Interface section. Hysteresis threshold is within 0.5 V of ground and $V_{CC}$ . Data is written or read out on clock's rising edge. Maximum clock rate is 2.0 MHz.
12	Data (I/O)		Data I/O line for the MCU Interface section. Both address and data are provided to/from this pin. Input threshold is within 0.5 V of ground and $V_{CC}$ . Data is written or read out on clock's rising edge.
13	MCU Clk Out (Output)		<p>The microprocessor clock output is derived from the reference oscillator and a programmable divider with divide ratios of 2 to 312.5. It can be used to drive a microprocessor and thereby reduce the number of crystals required in the system design. The driver has an internal resistor in series with the output which can be combined with an external capacitor to form a low-pass filter to reduce radiated noise on the PCB. This output also functions as the output for the counter test modes.</p> <p>1) For the MC33411A the Clk Out can be disabled via the MCU interface.</p> <p>2) For the MC33411B this output is always active (on).</p>
14	Gnd Digital		Ground for the Data, MCU Clk Out, and $F_{ref}$ Out digital Outputs. A direct connection to the ground plane is strongly recommended.

**NOTE:** 1. All  $V_{CC}$  pins must be within  $\pm 0.5$  V of each other.

# MC33411A/B

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol/Type	Description	Description
15, 16	F <sub>ref</sub> In, F <sub>ref</sub> Out		<p>Reference Frequency Input for various portions of the circuit, including the PLLs, SCF clock, etc. A crystal (4 to 18.25 MHz) may be connected as shown, or an external frequency source may be capacitor coupled to Pin 15. See text for crystal requirements.</p> <ol style="list-style-type: none"> <li>1) For the MC33411A the F<sub>ref</sub> Out can be disabled via the MCU interface.</li> <li>2) For the MC33411B this output is always active (on).</li> </ol>
17	DS Out (Output)		Data Slicer Output (open collector with internal 100 kΩ pull-up resistor).
18	Tx Out (Output)		Tx Out is the Tx path audio output. Internally this pin has a low-pass filter circuitry with -3.0 dB bandwidth of 4.0 kHz. Tx gain and mute are programmable through the MCU interface. This pin is sensitive to load capacitance.
20	C Out (Output)		C Out is the compressor output.
19	Lim In (Input)		Lim In is the limiter input. This pin is internally biased and has an input impedance of 400 kΩ. Lim In must be ac-coupled.
21	C <sub>cap</sub>		C <sub>cap</sub> is the compressor rectifier filter capacitor pin. It is recommended that an external filter capacitor to V <sub>CC</sub> audio be used. A practical capacitor range is 0.1 to 1.0 μF. The recommended value is 0.47 μF.

**NOTE:** 1. All V<sub>CC</sub> pins must be within ±0.5 V of each other.

# MC33411A/B

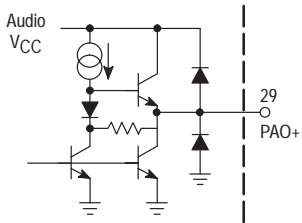

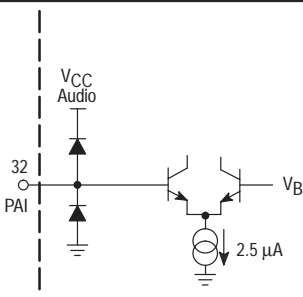

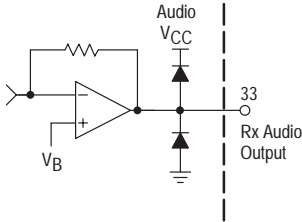

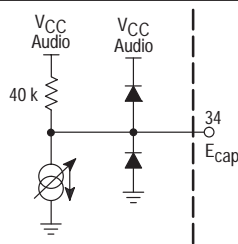

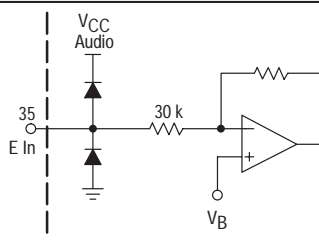

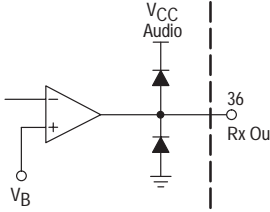

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol/Type	Description	Description
22	C In (Input)		C In is the compressor input. This pin is internally biased and has an input impedance of 12.5 kΩ. C In must be ac-coupled.
23	V <sub>CC</sub> Audio (Input)		Supply input for the audio section, filters, A/D Converters, and Data Slicer. Allowable range is 2.7 to 5.5 V. Good bypassing is required.
24	MCO (Output)		Output of the Microphone amplifier. Maximum output swing is $\approx 3.0 V_{pp}$ for $V_{CC} \geq 3.0 V$ . Maximum output current is $>1.0 mA$ peak.
25	MCI (Input)		Inverting input of the microphone amplifier. Gain and frequency response are set with external resistors and capacitors from this pin to the audio source and to MCO.
26	VAG (Output)		Analog ground for the audio section filters. VAG is equal to V <sub>B</sub> and is buffered from V <sub>B</sub> . Maximum current which can be sourced from this pin is 500 μA.
27	V <sub>B</sub> (Output)		An internal 1.5 V reference for several sections. This voltage is adjustable with bits 3/20–17. Maximum source current is 100 μA. PSRR, noise and crosstalk depends on the external capacitor.
28	V <sub>CC</sub> PA (Input)		Supply pin for the power amplifier outputs. Allowable range is 2.7 to 5.5 V. Good bypassing is required.

**NOTE:** 1. All V<sub>CC</sub> pins must be within  $\pm 0.5 V$  of each other.

# MC33411A/B

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol/Type	Description	Description
29	PAO+ (Output)		Output of the second power amplifier. This amplifier is set for unity inverting gain and is driven by PAO-. Maximum swing is $2.9 V_{pp}$ and maximum output current is $>5.0 \text{ mA}$ peak. DC level is $\approx 1.5 \text{ V}$ .
30	PAO- (Output)	Same as Pin 29.	Output of the first power amplifier. Its gain is set with external resistors and capacitors from this pin to PAI. Output capability is the same as Pin 28.
31	Gnd PA		Ground pin for the power amplifier outputs. A direct connection to a ground plane is strongly recommended.
32	PAI (Input)		Inverting input of the power amplifier. Gain and frequency response are set with external resistors and capacitors from this pin to the audio source and to PAO-.
33	E Out (Output)		Expander output. This output is sensitive to load capacitance. Maximum output signal level is $\approx 2.5 V_{pp}$ . Maximum output current is $>1.0 \text{ mA}$ .
34	Ecap		E <sub>cap</sub> is the expander rectifier filter capacitor pin. Connect an external filter capacitor between V <sub>CC</sub> audio and E <sub>cap</sub> . The recommended capacitance range is 0.1 to 1.0 $\mu\text{F}$ . The suggested value is 0.47 $\mu\text{F}$ .
35	E In (Input)		The expander input pin is internally biased and has input impedance of 30 k $\Omega$ .
36	Rx Out (Output)		Rx Out is the Rx audio output. An internal low-pass filter has a $-3.0 \text{ dB}$ bandwidth of 4.0 kHz.

**NOTE:** 1. All V<sub>CC</sub> pins must be within  $\pm 0.5 \text{ V}$  of each other.

# MC33411A/B

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol/Type	Description	Description
37	RSSI In (Input)		Voltage input to RSSI A/D converter. Full scale is 0 to 1.6 V.
38	Rx Audio In (Input)		Input to the Rx Audio Path. Input impedance is 600 k $\Omega$ . Input signal must be capacitor coupled
39	DS In (Input)		Input for the digital data from the RF Receiver section. Input impedance is 250 k $\Omega$ . Hysteresis is internally provided. Input signal level must be between 50 and 700 mVpp.
40	Gnd Audio		Ground pin for the audio section. A direct connection to a ground plan is strongly recommended.
41	LO2 Out (Output)		Buffered output of the 2nd LO. This high frequency output is a current, requiring an external pullup resistor.
42	LO2 V <sub>CC</sub> (Input)		Supply pin for the LO2 section. Allowable range is 2.7 to 5.5 V and must be within 0.5 V of all other V <sub>CC</sub> pins. Good bypassing is required and isolation with a 10 $\Omega$ resistor is recommended.

**NOTE:** 1. All V<sub>CC</sub> pins must be within  $\pm 0.5$  V of each other.

# MC33411A/B

## PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol/Type	Description	Description
43, 45	LO2+, LO2-		The 2nd LO. External tank components are required. The internal capacitance across the pins is adjustable from 0 to 7.6 pF for fine tuning performance with bits 7/20-18.
44	LO2 Ctl (Input)		LO2 Control is the dc control input for this VCO. Typically it is the output of the low-pass filter fed from the phase detector output.
46	LO2 Gnd		Ground pin for the LO2 section. A direct connection to a ground plane is strongly recommended.
47	LO2PD (Output)		LO2 Phase Detector Output. The output either sources or sinks current, or neither, depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the PLL reference frequency are present. Output current is either $\pm 100 \mu\text{A}$ or $\pm 400 \mu\text{A}$ , selectable with bit 3/14.
48	LO2 Gnd		Ground pin for the LO2 section. A direct connection to a ground plane is strongly recommended.

**NOTE:** 1. All  $V_{CC}$  pins must be within  $\pm 0.5$  V of each other.

# MC33411A/B

## FUNCTIONAL DESCRIPTION

The following text, graphics, tables and schematics are provided to the user as a source of valuable technical information about the MC33411. This information originates from thorough evaluation of the device performance. This data was obtained by using units from typical wafer lots. It is important to note that the forgoing data and information was from a limited number of units. By no means is the user to assume that the data following is a guaranteed parametric. Only the minimum and maximum limits identified in the electrical characteristics tables found earlier in the spec are guaranteed.

Note: In the following descriptions, control bits in the MCU Serial Interface for the various functions will be identified by register number and bit number. For example, bit 3/19 indicates bit 19 of register 3. Bits 5/14–11 indicates register 5, bits 14 through 11. Please refer to Figure 1.

### General Circuit Description

The MC33411A/B is a low power baseband IC designed to interface with the MC13145 UHF Wideband Receiver and MC13146 Transmitter for applications up to 2.0 GHz. The devices are primarily designated to be used for 900 MHz ISM band in a CT-900, low power, dual conversion cordless phone, but other applications such as data links with analog processing could be developed. This device contains complete baseband transmit and receive processing sections, a transmit and receive PLL section, a programmable PLL second local oscillator usable to 80 MHz,

RSSI and low battery detect circuitry and serial interface for a microprocessor.

"A" versions of the device have the ability to disable either the reference oscillator or MCU clock outputs. This feature is useful for systems where the MCU has an internal clock, allowing the user to place the MC33411 into Inactive (lowest power consumption) mode. The "A" version is also useful for systems where the MCU has a dedicated clock source, allowing for lower power consumption from the MC33411 by disabling the MCU clock output.

"B" versions of the device are intended for systems where the MCU clock will always be driven from the MC33411. These bits are purposefully "hard-wired" to the enable state to ensure proper operation of the reference oscillator and MCU clock output even during battery discharge/recharge cycles.

All internal registers are completely static – no refreshing is required under normal operation conditions.

### DC Current

Figures 2 through 5 are the current consumption for Inactive (MC33411 "A" version only), Standby, Receive, and Active modes versus supply voltages. Figures 6 and 7 show the typical behavior of current consumption in relation to temperature.

Figure 8 illustrates the effect of the MCU clock output frequency to supply current during Active mode.

### Transmit Speech Processing System

This portion of the audio path goes from "Tx Audio" to "Tx Out". The gain of the microphone amplifier is set with external resistors to receive the audio from the microphone hybrid or any other audio source. The MCO output has rail-to-rail capability. The "Tx Audio" pin will be ac-coupled. The audio transmit signal path includes automatic level control (ALC) (also referred to as the Compressor), Tx mute, limiter, filters, and Tx gain adjust. The ALC provides "soft" limiting to the output signal swing as the input voltage slowly increases. With this technique the gain is slightly lowered to help reduce distortion of the audio signal. The limiter section provides hard limiting due to rapidly changing signal levels, or transients. The ALC, TX mute, and limiter functions can be enabled or disabled via the MCU serial interface. The Tx gain adjust can also be remotely controlled to set different desired signal levels.

The adjustable gain stage provides 20 levels of gain in 1.0 dB increments. It is controlled with bits 7/9–5 as shown in Table 1. The effect of the gain setting under various ALC/Limiter On/Off settings is shown in Figure 9.

The Low-Pass Filter before the gain stage is a switched capacitor filter with a corner frequency at 3.7 kHz. This

frequency is dependent upon the SCF clock, nominally set to 165 kHz and is directly proportional to the SCF clock. The filter response for inband, ripple, wideband, as well as phase and group delay, are shown in Figures 10 through 14.

The mute switch at Pin 18 will mute a minimum of 60 dB. Bit 6/2 controls the mute. The limiter can be disabled by programming a logic 1 into 6/5.

The compressor with ALC transfer characteristic is shown in Figure 15. The ALC gain is controlled by bits 6/11–12. If both bits are programmed to a logic 0, the ALC gain is set to 5.0 dB. If bit 6/11 is set to a logic 1, the ALC gain will be set to 10 dB, whereas if bit 6/12 is set to a logic 1 the ALC gain will be 25 dB. The ALC function may be disabled by programming a logic 1 into bit 6/6.

The compressor low maximum gain can be set with bit 6/8. Programming this bit to a logic 0 sets the maximum gain to 23 dB. A lower maximum gain, nominally 13.5 dB, is achieved by programming the bit to a logic 1. The entire compressor can be bypassed (i.e., 0 dB) by programming bit 6/4 to a logic 1.

Figures 16 through 22 describe the characteristics of the compressor, ALC, and limiter.

Figure 22. Tx Output Audio Response (Lim off, R6/12 = 1)

**Data Slicer**

The data slicer will receive the low level digital signal from the RF receiver section at Pin 39. The input signal to the data slicer must be >200 mVpp. Hysteresis of 40 mV is internally provided. The output of the data slicer will be same waveform, but with an amplitude of 0 to V<sub>CC</sub>, and can be observed at Pin 17 if bits 5/9–8 are set to 00. The output can be inverted by setting bit 5/9 = 1. The data slicer can be disabled by setting bit 5/8 = 1.

**Receive Audio Path**

The Receive Audio Path (Pins 38, 36–33) consists of an anti-aliasing filter, a low-pass filter, side tone attenuator, gain adjust stage, a mute switch, expander and volume control.

The switched capacitor low-pass filter is an 8 pole filter, with a corner frequency at 3.8 kHz. This is designed to provide bandwidth limiting in the audio range.

The gain stage provides 20 dB of gain adjustment in 1.0 dB steps, measured from Pin 38 to 36. Bits 7/4–0 are used to set the gain according to Table 3. The mute switch, controlled by bit 6/1, will mute a minimum of 60 dB.

When the compressor output is within 3.0 dB of the expander input level, the Rx output (Pin 36) can be attenuated (referenced to the expander output) by bits 6/10–9. For 6/10–9 = 00, the attenuation is 0 dB. For the other combinations, 6/10–9 = 01, attenuation = 3.0 dB; 6/10–9 = 10, attenuation = 6.0 dB; and 6/10–9 = 11, attenuation = 10.4 dB (See Table 2).

The expander can be bypassed by setting bit 6/3 = 1.

Table 3 shows the various gain control settings which can be accessed in Register 7. Table 5 is the volume control settings, also located in Register 7.

Figures 23 through 31 illustrate the various characteristics of the receive audio path.

**Power Amplifiers**

The power amplifiers (Pins 29, 30, 32) are designed to drive the earpiece in a handset, or the telephone line via a hybrid circuit in the base unit. Each output (PAO+ and PAO-) can source and sink 5.0 mA, and can swing  $1.3 V_{pp}$  each. For high impedance loads, each output can swing  $2.7 V_{pp}$  ( $5.4 V_{pp}$  differential). The gain of the amplifiers is set with a feedback resistor from Pin 30 to 32, and an input resistor at Pin 32. The differential gain is 2x the resistor ratio. Capacitors

can be used for frequency shaping. The pins' dc level is  $V_B$  ( $\approx 1.5 V$ ).

The Mute switch, controlled with bit 6/0, will provide 60 dB of muting with a 50 k $\Omega$  feedback resistor. The amount of muting will depend on the value of the feedback resistor.

Figures 32 and 33 show the power amplifier swing/distortion for  $V_{CC} = 3.6 V$ , and Figure 34 illustrates the maximum swing capability for various value of  $V_{CC}$ .

**Figure 34. Power Amplifier Maximum Output Swing versus VCC**

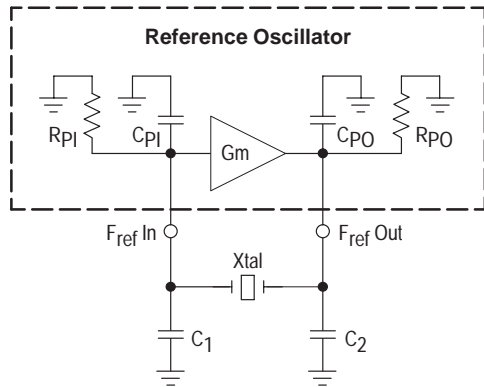

**Reference Oscillator/MCU Clk Out**

The reference oscillator provides the frequency basis for the three PLLs, the switched capacitor filters, and the MCU clock output. The source for the reference clock can be a crystal in the range of 4.0 to 18.25 MHz connected to Pins 15 & 16, or it can be an external source connected to F<sub>ref In</sub> (Pin 15). The reference frequency is directed to:

- d. A programmable 12-bit counter (register bits 4/11-0) to provide the reference frequency for the three PLLs. The 12-bit counter is to be set such that, in conjunction with the programmable counters within each PLL, the proper frequencies can be produced by each VCO.
- e. A programmable 6-bit counter (register bits 4/17-12), followed by a +2 stage, to set the frequency for the switched capacitor filters to 165 kHz, or as close to that as possible.
- f. A programmable 3-bit counter (register bits 7/16-14) which provides the MCU clock output (see Tables 6 and 6).

A representation of the reference oscillator is given by Figures 39 and 36.

**Figure 35. Reference Oscillator Schematic**

**Figure 36. Reference Oscillator Input and Output Impedance**

Input Impedance ( $R_{pI} // C_{pI}$ )	11.6 k $\Omega$ // 2.9 pF
Output Impedance ( $R_{pO} // C_{pO}$ )	4.5 k $\Omega$ // 2.5 pF

Figures 37 and 38 show a typical gain/phase response of the oscillator. Load capacitance ( $C_L$ ), equivalent series resistance (ESR), and even supply voltage will have an effect on the oscillator response as shown in Figures 39 and 40. It should be noted that optimum performance is achieved when  $C_1$  equals  $C_2$  ( $C_1/C_2 = 1$ ).

Figure 41 represents the ESR versus crystal load capacitance for the reference oscillator. This relationship was defined by using a 6.0 dB minimum loop gain margin at 3.6 V. This is considered the minimum gain margin to guarantee oscillator start-up.

Oscillator start-up is also significantly affected by the crystal load capacitance selection. In Figure 39, the relationship between crystal load capacitance and ESR can be seen. The lower the load capacitance the better the performance.

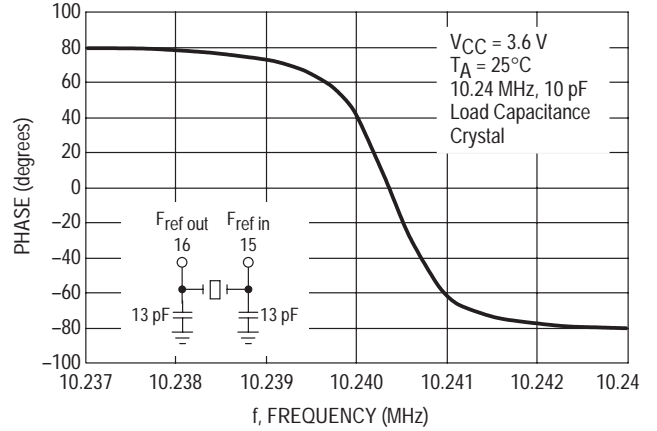

Given the desired crystal load capacitance,  $C_1$  and  $C_2$  can be determined from Figure 42. It should also be pointed out that current consumption increases when  $C_1 \neq C_2$ .

Be careful not to overdrive the crystal. This could cause a noise problem. An external series resistor on the crystal output can be added to reduce the drive level, if necessary.

### Transmit and Receive (LO1) PLL Sections

The transmit and receive PLLs (Pins 6–9 and 1–4, respectively) are designed to be part of a 900 MHz system. In a typical application the Transmit PLL section will be set up to generate the transmit frequency, and the Receive PLL section will be set up to generate the LO1 frequency. The two sections are identical, and function independently. External requirements for each include a low-pass filter, a 900 MHz VCO, and a 64/65 or 128/129 dual modulus prescaler.

The frequency output of the VCO is to be reduced by the dual modulus prescaler, and then input to the MC33411 (at Pin 8 or 2). That frequency is then further reduced by the programmable 13-bit counter (bits 1/19–7 or 2/19–7), and provided to one side of the Phase Detector, where it is compared with the PLL reference frequency. The output of the phase detector (at Pin 6 or 4) is a Three-State charge pump which drives the VCO through the low-pass filter. Bits 1/20 and 2/20 set the gain of each of the two charge pumps to either 100/2π μA/radian or 400/2π μA/radian. The polarity of the two phase detector outputs is set with bits 1/21 and 2/21. If the bit = 0, the appropriate PLL is configured to operate with a non-inverting low-pass filter/VCO combination. If the low-pass filter/VCO combination is inverting, the polarity bit should be set to 1.

The 7-bit A and A' counters (bits 1/6–0 and 2/6–0) are to be set to drive the Modulus Control input of the 64/65 or 128/129 dual modulus prescalers. The Modulus Control outputs (Pins 9 and 1) can be set to either a voltage mode (logic 1) or a current mode (logic 0) with bit 3/16.

To calculate the settings of the N and A registers, the following procedure is used:

$$\frac{f_{VCO}}{f_{PLL}} = Nt \text{ (Nt must be an integer)} \quad (1)$$

$$\frac{Nt}{P} = N \quad (2)$$

$$A = \text{Remainder of Equation 2} \text{ (decimal part of } N \times P) \quad (3)$$

where:  $f_{VCO}$  = the VCO frequency  
 $f_{PLL}$  = the PLL Reference Frequency set within the MC33411  
 P = the smaller divisor of the dual modulus prescaler (64 for a 64/65 prescaler)  
 N = the whole number portion is the setting for the N (or N') counter within the MC33411  
 A = the setting for the A (or A') counter within the MC33411

For example, if the VCO is to provide 910 MHz, and the internal PLL reference frequency is 50 kHz, then the equations yield:

$$Nt = \frac{910 \times 10^6}{50 \times 10^3} = 18,200$$

$$N = \frac{18,200}{64} = 284.375$$

$$A = 0.375 \times 64 = 24$$

The N register setting is 284 (0 0001 0001 1100), and the A register setting is 24 (001 1000).

## MC33411A/B

### 2nd LO (LO2)

This PLL is designed to be the 2nd Local Oscillator in a typical 900 MHz system, and is designed for frequencies up to 80 MHz. The VCO and varactor diodes are included, and are to be used with an external tank circuit (Pins 43–45).

Bits 4/20–18 are used to select an internal capacitor, with a value in the range of 0 to 7.6 pF, to parallel the varactor diodes and the tank's external capacitor. This permits a certain amount of fine tuning of the oscillator's performance. See Table 7.

A buffered output is provided to drive, e.g., a mixer. The frequency is set with the programmable 14-bit counter (bits 3/13–0) in conjunction with the PLL reference frequency. For example, if the reference frequency is 50 kHz,

and the 2nd LO frequency is to be 63.3 MHz, the 14-bit counter needs to be set to 1266<sub>d</sub> (00 0100 1111 0010). The output level is dependent on the value of the impedance at Pin 41, partly determined by the external pull-up resistor.

The output of the phase detector is a Three-State charge pump which drives the varactor diodes through an external low-pass filter. Bit 3/14 sets the gain of the charge pump to either  $100/2\pi$   $\mu\text{A}/\text{radian}$  (logic 0) or  $400/2\pi$   $\mu\text{A}/\text{radian}$  (logic 1). Bit 3/15 sets its polarity – if 0, the PLL is configured to operate with a non-inverting low-pass filter/VCO combination. If the low-pass filter/VCO combination is inverting, the polarity bit should be set to 1. Please note that the 2nd LO VCO on the MC33411 is of the non-inverting type. Figures 43 through 45 describe the response of the 2nd LO.

**Table 7. LO2 Capacitor Select Programming**

**Loop Filter Characteristics**

Let's consider the following discussion on loop filters. The fundamental loop characteristics, such as capture range, loop bandwidth, lock-up time, and transient response are controlled externally by loop filtering.

Figure 96 is the general model for a Phase Lock Loop (PLL).

**Figure 46. PLL Model**

Where:

- $K_{pd}$  = Phase Detector Gain Constant
- $K_f$  = Loop Filter Transfer Function
- $K_o$  = VCO Gain Constant
- $K_n$  = Divide Ratio (N)
- $f_i$  = Input frequency
- $f_o$  = Output frequency
- $f_o/N$  = Feedback frequency divided by N

From control theory the loop transfer function can be represented as follows:

$$A = \frac{K_{pd} K_f K_o}{K_n} \text{ Open loop gain}$$

$K_{pd}$  can be either expressed as being  $200 \mu A/4\pi$  or  $800 \mu A/4\pi$ . More details about performance of different type PLL loops, refer to Motorola application note AN535.

The loop filter can take the form of a simple low pass filter. A current output, type 2 filter will be used in this discussion since it has the advantage of improved step response, velocity, and acceleration.

The type 2 low pass filter discussed here is represented as follows:

**Figure 47. Loop Filter with Additional Integrating Element**

From Figure 97, capacitor C1 forms an additional integrator, providing the type 2 response, and filters the discrete current steps from the phase detector output. The function of the additional components R2 and C2 is to create a pole and a zero (together with C1) around the 0 dB point of the open loop gain. This will create sufficient phase margin for stable loop operation.

In Figure 98, the open loop gain and the phase is displayed in the form of a Bode plot. Since there are two integrating functions in the loop, originating from the loopfilter and the VCO gain, the open loop gain response follows a second order slope (-40 dB/dec) creating a phase of -180 degrees at the lower and higher frequencies. The filter characteristic needs to be determined such that it is adding a

pole and a zero around the 0 dB point to guarantee sufficient phase margin in this design ( $Q_p$  in Figure 98).

**Figure 48. Bode Plot of Gain and Phase in Open Loop Condition**

The open loop gain including the filter response can be expressed as:

$$A_{openloop} = \frac{K_{pd} K_o (1 + j\omega(R_2 C_2))}{j\omega K_n \left( j\omega \left( 1 + j\omega \left( \frac{R_2 C_1 C_2}{C_1 + C_2} \right) \right) \right)} \quad (4)$$

The two time constants creating the pole and the zero in the Bode plot can now be defined as:

$$T_1 = \frac{R_2 C_1 C_2}{C_1 + C_2} \quad T_2 = R_2 C_2 \quad (5)$$

By substituting equation (5) into (4), it follows:

$$A_{openloop} = \left( \frac{K_{pd} K_o T_1}{\omega^2 C_1 K_n T_2} \right) \left( \frac{1 + j\omega T_2}{1 + j\omega T_1} \right) \quad (6)$$

The phase margin (phase + 180) is thus determined by:

$$Q_p = \arctan(\omega T_2) - \arctan(\omega T_1) \quad (7)$$

At  $\omega = \omega_p$ , the derivative of the phase margin may be set to zero in order to assure maximum phase margin occurs at  $\omega_p$  (see also Figure 98). This provides an expression for  $\omega_p$ :

$$\frac{dQ_p}{d\omega} = 0 = \frac{T_2}{1 + (\omega T_2)^2} - \frac{T_1}{1 + (\omega T_1)^2} \quad (8)$$

$$\omega = \omega_p = \frac{1}{\sqrt{T_2 T_1}} \quad (9)$$

Or rewritten:

$$T_1 = \frac{1}{\omega_p^2 T_2} \quad (10)$$

By substituting into equation (7), solve for T2:

$$T_2 = \frac{\tan\left(\frac{Q_p}{2} + \frac{\pi}{4}\right)}{\omega_p} \quad (11)$$

By choosing a value for  $\omega_p$  and  $Q_p$ ,  $T_1$  and  $T_2$  can be calculated. The choice of  $Q_p$  determines the stability of the loop. In general, choosing a phase margin of 45 degrees is a good choice to start calculations. Choosing lower phase margins will provide somewhat faster lock-times, but also generate higher overshoots on the control line to the VCO. This will present a less stable system. Larger values of phase margin provide a more stable system, but also increase lock-times. The practical range for phase margin is 30 degrees up to 70 degrees.

The selection of  $\omega_p$  is strongly related to the desired lock-time. Since it is quite complicated to accurately calculate lock time, a good first order approach is:

$$T_{lock} \approx \frac{3}{\omega_p} \quad (12)$$

Equation (12) only provides an order of magnitude for lock time. It does not clearly define what the exact frequency difference is from the desired frequency and it does not show the effect of phase margin. It assumes, however, that the phase detector steps up to the desired control voltage without hesitation. In practice, such step response approach is not really valid. If the two input frequencies are not locked, their phase maybe momentarily zero and force the phase detector into a high impedance mode. Hence, the lock times may be found to be somewhat higher.

In general,  $\omega_p$  should be chosen far below the reference frequency in order for the filter to provide sufficient attenuation at that frequency. In some applications, the reference frequency might represent the spacing between channels. Any feedthrough to the VCO that shows up as a spur might affect adjacent channel rejection. In theory, with the loop in lock, there is no signal coming from the phase detector. But in practice small current pulses and leakage currents will be supplied to both the VCO and the phase detector. The external capacitors may show some leakage, too. Hence, the lower  $\omega_p$ , the better the reference frequency is filtered, but the longer it takes for the loop to lock.

As shown in Figure 98, the open loop gain at  $\omega_p$  is 1 (or 0 dB), and thus the absolute value of the complex open loop gain as shown in equation (6) solves  $C_1$ :

$$C_1 = \left( \frac{K_{pd}K_oT_1}{\omega^2K_nT_2} \right) \sqrt{\frac{(1 + \omega_pT_2)^2}{(1 + \omega_pT_1)^2}} \quad (13)$$

With  $C_1$  known, and equation (5) solve  $C_2$  and  $R_2$ :

$$C_2 = C_1 \left( \frac{T_2}{T_1} - 1 \right) \quad (14)$$

$$R_2 = \frac{T_2}{C_2} \quad (15)$$

The VCO gain is dependent on the selection of the external inductor and the frequency required. The free running frequency of the VCO is determined by:

$$f = \frac{1}{2\pi\sqrt{LC_T}} \quad (16)$$

In which  $L$  represents the external inductor value and  $C_T$  represents the total capacitance (including internal capacitance) in parallel with the inductor. The VCO gain can be easily calculated via the internal varicap transfer curve shown in Figure 43.

As can be derived from Figure 43, the varicap capacitance changes 2.0 pF over the voltage range from 1.0 V to 3.0 V:

$$\Delta C_{var} = \frac{2.0 \text{ pF}}{2.0 \text{ V}} \quad (17)$$

Combining (16) with (17) the VCO gain can be determined by:

$$K_o = \frac{1}{j2.0V} \left\{ \frac{1}{2\pi\sqrt{LC_T}} - \frac{1}{2\pi\sqrt{L\left(C_T + \frac{\Delta C_{var}}{2}\right)}} \right\} \quad (18)$$

Although the basic loopfilter previously described provides adequate performance for most applications, an extra pole may be added for additional reference frequency filtering. Given that the channel spacing is based on the reference frequency, and any feedthrough to the first LO may effect parameters like adjacent channel rejection and intermodulation. Figure 100 shows a loopfilter architecture incorporating an additional pole.

Figure 49. Loop Filter with Additional Integrating Element

For the additional pole formed by  $R_3$  and  $C_3$  to be efficient, the cut-off frequency must be much lower than the reference frequency. However, it must also be higher than  $\omega_p$  in order not to compromise phase margin too much. The following equations were derived in a similar manner as for the basic filter previously described.

Similarly, it can be shown:

$$A_{\text{openloop}} = -\frac{K_{pd}K_o}{K_n\omega^2((C1 + C2 + C3) - \omega^2C1C2C3R2R3)} + \frac{1 + j\omega T2}{1 + j\omega T1} \quad (19)$$

In which:

$$T1 = \frac{(C1 + C2)T2 + (C1C2)T3}{C1 + C2 + C3 - \omega^2C1T2T3} \quad (20)$$

$$T2 = R2C2 \quad (21) \quad T3 = R3C3 \quad (22)$$

From T1 it can be derived that:

$$C2 = \frac{(T1 + T2)C3 - C1(T2 + T3 - T1 + \omega^2T1T2T3)}{T3 - T1} \quad (23)$$

In analogy with (13), by forcing the loopgain to 1 (0 dB) at  $\omega_p$ , we obtain:

$$C1(T1 + T2) + C2T3 + C3T2 = \left(\frac{K_{pd}K_o}{K_n\omega_p^2}\right) \sqrt{\frac{1 + (\omega_p T2)^2}{1 + (\omega_p T1)^2}} \quad (24)$$

Solving for C1:

$$C1 = \frac{(T2 - T1)T3C3 - (T3 - T1)T2C3 + (T3 - T1)\left(\frac{K_{pd}K_o T1}{\omega_p^2 K_n}\right) \sqrt{\frac{1 + (\omega_p T2)^2}{1 + (\omega_p T1)^2}}}{(T3 - T1)T2 + (T3 - T1)T3 - (T2 + T3 - T1 + \omega_p^2 T1 T2 T3)T3} \quad (25)$$

By selecting  $\omega_p$  via (12), the additional time constant expressed as T3, can be set to:

$$T3 = \frac{1}{K\omega_p} \quad (26)$$

The K-factor shown determines how far the additional pole frequency will be separated from  $\omega_p$ . Selecting too small of a K-factor, the equations may provide negative capacitance or resistor values. Too large of a K-factor may not provide the maximum attenuation.

By selecting R3 to be 100 k $\Omega$ , C3 becomes known and C1 and C2 can be solved from the equations. By using equations (11) and (10), time constants T2 and T1 can be derived by selecting a phase margin. Finally, R2 follows from T2 and C2.

A test circuit with the following components and conditions was constructed with these results:

Loop Filter (See Figure 100):

- C1 = 470 pF
- R2 = 68 k $\Omega$
- C2 = 3.9 nF
- R3 = 270 k $\Omega$
- C3 = 82 pF

LO2 Tank:

- Ctotal = 39.3 pF
- Lext = 150 nH, Q = 50 @ 250 MHz
- Reference Frequency = 10.24 MHz (unadjusted)
- R Counter = 205
- LO2 Counter = 1266
- AC Load = 25  $\Omega$
- Frequency of LO2 = 63.258 MHz
- Phase Noise @ 50 kHz offset = -107 dBc
- Sidebands @ 50 kHz & 100 kHz offsets = -69 dBc

#### Low Battery/ RSSI Voltage Measurement

Both the Low Battery (bits 5/23–18) and RSSI (bits 5/17–12) measurement circuits have a 6-bit A/D converter whose value may be read back via the SPI. The A/D's sample their voltages at a frequency equal to the internal SCF clock frequency divided by 128. The Low Battery Measurement A/D senses and divides by 2.5 the supply voltage (at Pin 23). Please note that the minimum Low Battery Detect (LBD) voltage is 2.7 V, since there is no guarantee that the device will operate below this value. The RSSI Measurement senses the voltage at Pin 37.

## MC33411A/B

These values are compared to the internal reference VB ( $\approx 1.5$  V) which is available at Pin 37. The value read back from the LBD A/D will therefore be approximately:

$$N(\text{for LBD}) \approx \frac{63 (V_{CC})}{2.5(V_B)(1.07)} \quad (27)$$

and for the RSSI

$$N(\text{for RSSI}) \approx \frac{63 (\text{RSSI Voltage})}{(V_B)(1.07)} \quad (28)$$

### VB Voltage Adjust and Characteristics

VB has a production tolerance of  $\pm 8\%$ , and can be adjusted over a  $\pm 9\%$  range using bits 3/20–17. The adjustment steps will be  $\approx 1.2\%$  each (See Table 8). If desired, VB can be used to bias external circuitry, as long as the load current on this pin does not exceed  $10 \mu\text{A}$ . VB varies by less than  $\pm 0.5\%$  over supply voltage, referenced to  $V_{CC} = 3.6$  V.

The value of the de-coupling capacitor connected from VB to ground affects both the noise and crosstalk from the receive and transmit audio paths, so the value should be chosen with caution. Figures 50 and 51 show this relationship.

Table 8. VB Voltage Reference Programming

V <sub>ref</sub> Adjust Bit #20	V <sub>ref</sub> Adjust Bit #19	V <sub>ref</sub> Adjust Bit #18	V <sub>ref</sub> Adjust Bit #17	V <sub>ref</sub> Adjust #	Voltage Reference Adjustment Amount

Figure 51. Crosstalk/Noise from E In to Tx Out versus VB Capacitor

### MCU Serial Interface

The MCU Serial Interface is a 3-wire interface, consisting of a Clock line, an Enable line, and a bi-directional Data line. The interface is always active, i.e., it cannot be powered down as all other sections of the MC33411 are disabled and enabled through this interface.

After the device power-up (or whenever a reset condition is required), the MCU should perform the following steps:

13. Initialize the Data line to a high impedance state.
14. Initialize the Clock line to a logic low.
15. Initialize the Enable line to a logic low.
16. Pulse the Clock line a minimum of once (RZ format) while leaving the Enable line continuously low. This places the SPI port into a known condition.
17. Load all registers with their desired initial values.

The clock (Return-to-Zero format) must be supplied to the MC33411 at Pin 11 to write or read data, and can be any frequency up to 2.0 MHz. The clock need not be present when data is not being transferred. The Enable line must be low when data is not being transferred.

Internally there are 7 data registers, 24-bits each, addressed with 4-bits ranging from \$h1 to \$h7 (see Tables 9 and 10). Register 5, bits 23–12 are read-only bits, while all other register bits are Read/Write. All unused/unimplemented bits are reserved for Motorola use only. The contents of the 7 registers can be read out at any time. All bits are written in, or read out, on the clock's positive transition. The write and read operations are as follows:

Figure 52. Writing Data to the MC33411

#### a. Write Operation:

- To write data to the MC33411, the following sequence is required (see Figure 3):
18. The Enable line is taken high.
  19. Five bits are entered:
    - The first bit must be a 0 to indicate a Write operation.
    - The next four bits identify the register address (0001–0111). The MSB is entered first.
  20. The Enable line is taken low. At this transition, the address is latched in and decoded.
  21. The Enable line is maintained low while the data bits are clocked in. The MSB is entered first, and the LSB last. If 24-bits are written to a register which has less than 24 active bits (e.g., register 6), the unassigned bits are to be 0.
  22. After the last bit is entered, the Enable line is to be taken high and then low. The falling edge of this pulse latches in the just entered data. The clock line must be at a logic low and must not transition in either direction during this Enable pulse.
  23. The Enable line must then be kept low until the next communication.
 

Note: If less than 24 bits are to be written to a data register, it is not necessary to enter the full 24 bits, as long as they are all lower order bits. For example, if bits 0–6 of a register are to be updated, they can be entered as 7 bits with 7 clock cycles in step 4 above. However, if this procedure is used, a minimum of 4 bits, with 4 clock pulses, must be entered.

Figure 53. Reading Data from the MC33411

#### b. Read Operation:

- To read the output bits (bits 5/23–12), or the contents of any register, the following sequence is required (see Figure 4):

1. The Enable line is taken high.
2. Five bits are entered:
  - The first bit must be a 1 to indicate a Read operation.
  - The next four bits identify the register address (0001–0111). The MSB is entered first.
3. The Enable line is taken low. At this transition, the address is latched in and decoded, and the contents of the selected register is loaded into the 24-bit output shift register. At this point, the Data line (Pin 12) is still an input.
4. While maintaining the Enable line low, the data is read out. The first clock rising edge will change the Data line to an output, and the MSB will be present on this line.
5. The full contents of the register are then read out (MSB first, LSB last) with a total of 24 clock rising edges, including the one in step 4 above. It is recommended that the MCU read the bits after the clock's falling edge.
6. After the last clock pulse, the Enable line is to be taken high and then low. The falling edge of this pulse returns the Data Pin to be an input. The clock line must be at a logic low and must not transition in either direction during this Enable pulse.
7. The Enable line must then be kept low until the next communication.

#### Power Supply/Power Saving Modes

The power supply voltage, applied to all  $V_{CC}$  pins, can range from 2.7 to 5.5 V. All  $V_{CC}$  pins must be within  $\pm 0.5$  V of each other, and each must be bypassed. It is recommended a ground plane be used, and all leads to the MC33411 be as short and direct as possible. To reduce the possibility of device latch-up, it is highly recommended that the Audio, Synthesizer and RF  $V_{CC}$  portions of the chip be isolated from the main supply through 10 to 25  $\Omega$  resistors (see the Evaluation PCB Schematic, Figure 54). This also provides RF-to-Audio noise isolation. The supply and ground pins are distributed as follows:

1. Pin 23 provides power to the audio section. Pin 40 is the ground pin.
2. Pin 28 provides power to the speaker amplifier section. Pin 31 is the ground pin.

3. Pin 3 provides power to the Rx PLL section. Pin 5 is the ground pin.
4. Pin 7 provides power to the Tx PLL section, and the MCU interface. Pin 5 is the ground pin.
5. Pin 42 provides power to the 2nd LO section. Pins 46 and 48 are the ground pins.
6. Pin 14 is the ground pin for the digital circuitry. Power for the digital circuitry is derived from Pin 23.

To conserve power, various sections can be individually disabled by using bits 5/7–0 and 6/7 (setting a bit to 1 disables the section).

1. Reference Oscillator Disable (bit 5/0) – The reference oscillator at Pins 15 and 16 is disabled, thereby denying a clock to the three PLLs and the switched capacitor filters. This function is not available on the “B” version.
2. Tx PLL Disable (bit 5/1) – The 13-bit and 7-bit counters, input buffer, phase detector, and modulus control blocks are disabled. The charge pump output at Pin 6 will be in a Hi-Z state.
3. Rx PLL Disable (bit 5/2) – The 13-bit and 7-bit counters, input buffer, phase detector, and modulus control blocks are disabled. The charge pump output at Pin 4 will be in a Hi-Z state.
4. LO2 PLL Disable (bit 5/3) – The VCO, 14-bit counter, output buffer, and phase detector are disabled. The charge pump output at Pin 47 will be in a Hi-Z state.
5. Power Amplifier Disable (bit 5/4) – The two speaker amplifiers are disabled. Their outputs will go to a high impedance state.
6. Rx Audio Path Disable (bit 5/5) – The anti-aliasing filter, low-pass filter, and variable gain stage are disabled.
7. Tx Audio Path Disable (bit 5/6) – Disables the microphone amplifier and low-pass filter.
8. Low Battery/RSSI Measurement Disable (bit 5/7) – Both 6-bit A/Ds are disabled.
9. Data Slicer Disable (bit 5/8) – The data slicer is disabled and DS Out goes to high impedance.
10. MCU Clock Disable (bit 6/7) – The MCU clock counter is disabled and the MCU Clock Output will be in a Hi-Z state. This function is not available on the “B” version.

Note: The 12-bit reference counter is disabled if the three PLLs are disabled (bits 5/1–3 = 1).

## MC33411A/B

### Evaluation PCB

The evaluation PCB is a versatile board which allows the MC33411 to be configured to analyze individual operating parameters or the complete audio transmit and receive paths.

The general purpose schematic and associated parts list for the PCB are given in Figure 54. With the jumpers

positioned as shown in the parts list (either shunt or open), the PCB is configured to analyze complete transmit and receive audio paths.

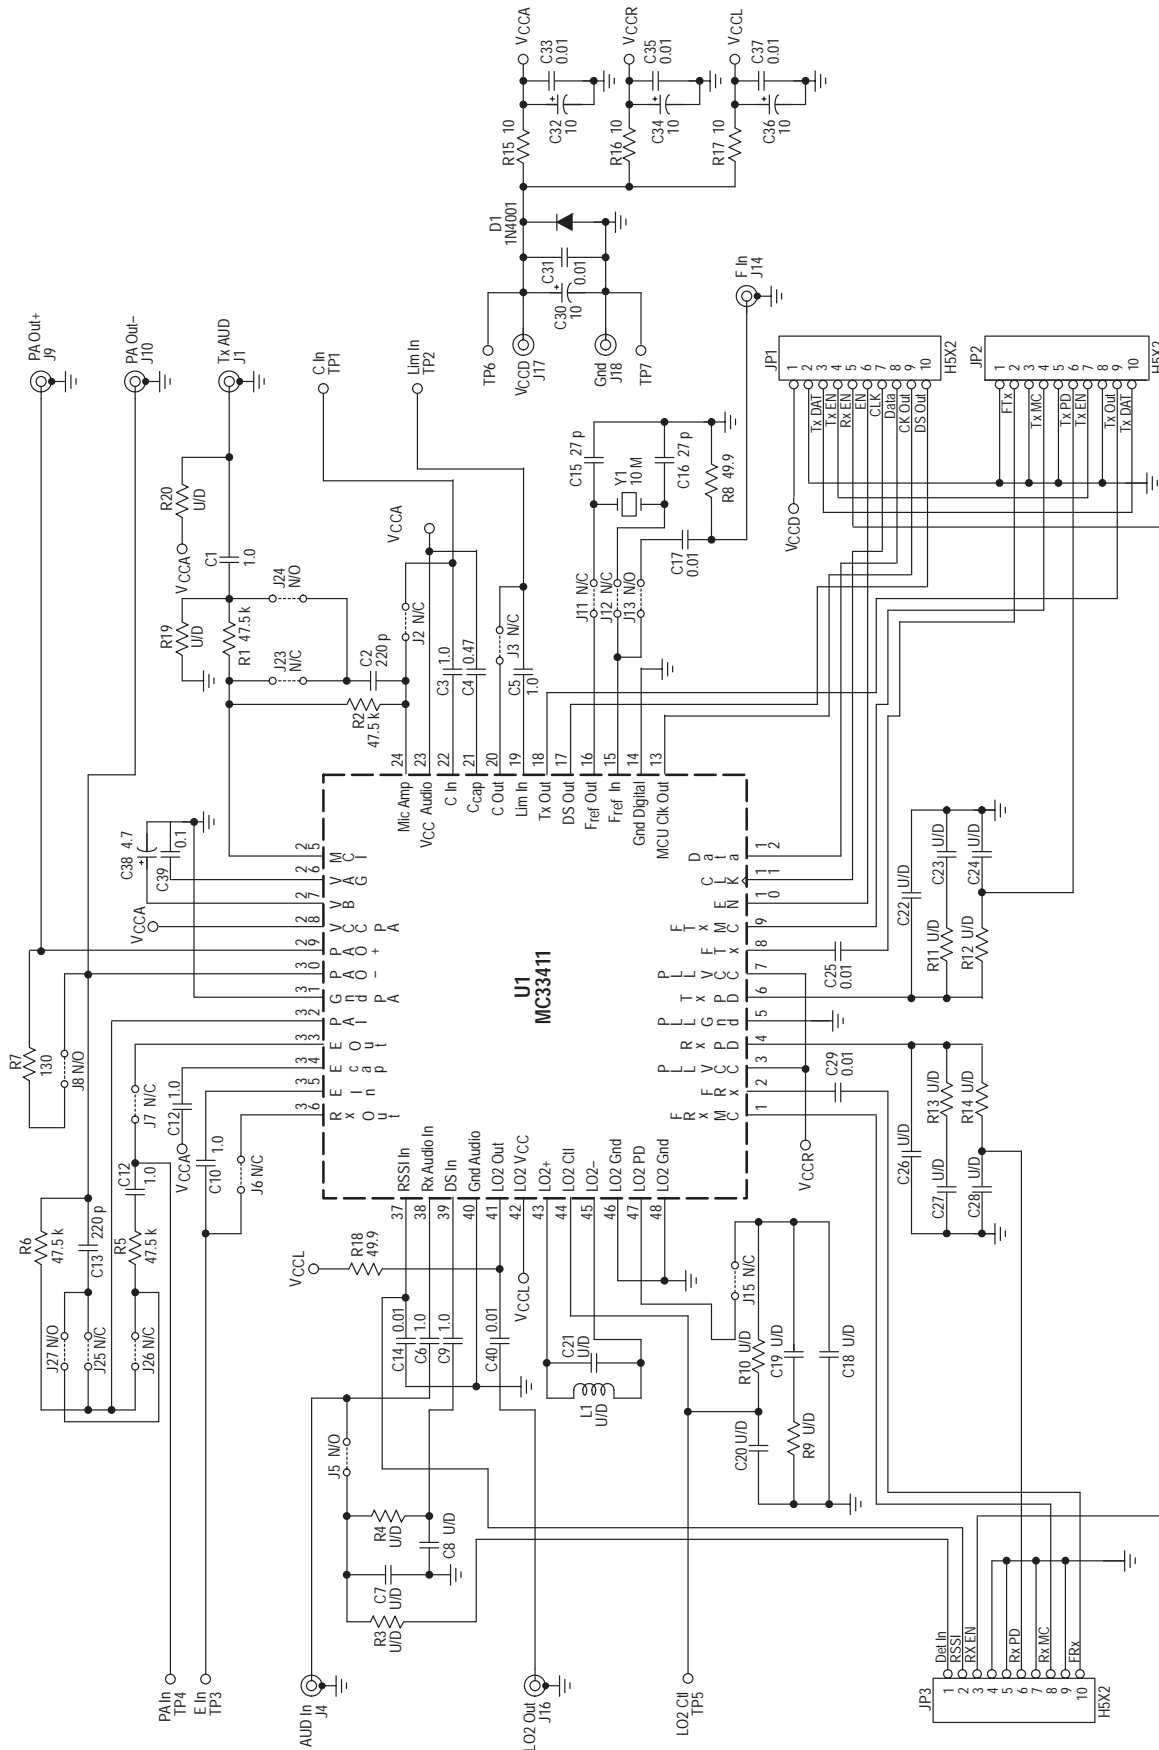

Parts lists as "user defined" can be installed to analyze other functions of the device. Table 3 lists these devices along with their respective functions.

# Digital-to-Analog Converters with Serial Interface

## CMOS LSI

The MC144110 and MC144111 are low-cost 6-bit D/A converters with serial interface ports to provide communication with CMOS microprocessors and microcomputers. The MC144110 contains six static D/A converters; the MC144111 contains four converters.

Due to a unique feature of these DACs, the user is permitted easy scaling of the analog outputs of a system. Over a 5 to 15 V supply range, these DACs may be directly interfaced to CMOS MPUs operating at 5 V.

- Direct R-2R Network Outputs
- Buffered Emitter-Follower Outputs
- Serial Data Input
- Digital Data Output Facilitates Cascading
- Direct Interface to CMOS  $\mu$ P
- Wide Operating Voltage Range: 4.5 to 15 V
- Wide Operating Temperature Range: 0 to 85°C
- Software Information is Contained in Document M68HC11RM/AD

## PIN ASSIGNMENTS

NC = NO CONNECTION

**MAXIMUM RATINGS\*** (Voltages referenced to  $V_{SS}$ )

Parameter	Symbol	Value	Unit
DC Supply Voltage	$V_{DD}$	- 0.5 to + 18	V
Input Voltage, All Inputs	$V_{in}$	- 0.5 to $V_{DD} + 0.5$	V
DC Input Current, per Pin	I	$\pm 10$	mA
Power Dissipation (Per Output) $T_A = 70^\circ\text{C}$ , MC144110 MC144111 $T_A = 85^\circ\text{C}$ , MC144110 MC144111	$P_{OH}$	30 50 10 20	mW
Power Dissipation (Per Package) $T_A = 70^\circ\text{C}$ , MC144110 MC144111 $T_A = 85^\circ\text{C}$ , MC144110 MC144111	$P_D$	100 150 25 50	mW
Storage Temperature Range	$T_{stg}$	- 65 to + 150	$^\circ\text{C}$

\* Maximum Ratings are those values beyond which damage to the device may occur.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields; however, it is advised that precautions be taken to avoid application of voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation it is recommended that  $V_{in}$  and  $V_{out}$  be constrained to the range  $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{DD}$ .

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either  $V_{SS}$  or  $V_{DD}$ ).

**ELECTRICAL CHARACTERISTICS** (Voltages referenced to  $V_{SS}$ ,  $T_A = 0$  to  $85^\circ\text{C}$  unless otherwise indicated)

**LINEARITY ERROR** (integral linearity). A measure of how straight a device's transfer function is, it indicates the worst-case deviation of linearity of the actual transfer function from the best-fit straight line. It is normally specified in parts of an LSB.

**Figure 1. D/A Transfer Function**

**Figure 2. Definition of Step Size**

**Figure 3. Serial Input, Positive Clock**

**Figure 4. Serial Input, Negative Clock**

## PIN DESCRIPTIONS

### INPUTS

#### **D<sub>in</sub>** **Data Input**

Six-bit words are entered serially, MSB first, into digital data input, D<sub>in</sub>. Six words are loaded into the MC144110 during each D/A cycle; four words are loaded into the MC144111.

The last 6-bit word shifted in determines the output level of pins Q1 Out and R1 Out. The next-to-last 6-bit word affects pins Q2 Out and R2 Out, etc.

#### **$\overline{\text{ENB}}$**

#### **Negative Logic Enable**

The  $\overline{\text{ENB}}$  pin must be low (active) during the serial load. On the low-to-high transition of  $\overline{\text{ENB}}$ , data contained in the shift register is loaded into the latch.

#### **CLK**

#### **Shift Register Clock**

Data is shifted into the register on the high-to-low transition of CLK. CLK is fed into the D-input of a transparent latch, which is used for inhibiting the clocking of the shift register when  $\overline{\text{ENB}}$  is high.

The number of clock cycles required for the MC144110 is usually 36. The MC144111 usually uses 24 cycles. See Table 1 for additional information.

## OUTPUTS

#### **D<sub>out</sub>** **Data Output**

The digital data output is primarily used for cascading the DACs and may be fed into D<sub>in</sub> of the next stage.

#### **R1 Out through R<sub>n</sub> Out** **Resistor Network Outputs**

These are the R-2R resistor network outputs. These outputs may be fed to high-impedance input FET op amps to bypass the on-chip bipolar transistors. The R value of the resistor network ranges from 7 to 15 k $\Omega$ .

#### **Q1 Out through Q<sub>n</sub> Out** **NPN Transistor Outputs**

Buffered DAC outputs utilize an emitter-follower configuration for current-gain, thereby allowing interface to low-impedance circuits.

## SUPPLY PINS

#### **V<sub>SS</sub>** **Negative Supply Voltage**

This pin is usually ground.

#### **V<sub>DD</sub>** **Positive Supply Voltage**

The voltage applied to this pin is used to scale the analog output swing from 4.5 to 15 V p-p.

**Table 1. Number of Channels vs Clocks Required**

Number of Channels Required	Number of Clock Cycles	Outputs Used on MC144110	Outputs Used on MC144111
1	6	Q1/R1	Q1/R1
2	12	Q1/R1, Q2/R2	Q1/R1, Q2/R2
3	18	Q1/R1, Q2/R2, Q3/R3	Q1/R1, Q2/R2, Q3/R3
4	24	Q1/R1, Q2/R2, Q3/R3, Q4/R4	Q1/R1, Q2/R2, Q3/R3, Q4/R4
5	30	Q1/R1, Q2/R2, Q3/R3, Q4/R4, Q5/R5	Not Applicable
6	36	Q1/R1, Q2/R2, Q3/R3, Q4/R4, Q5/R5, Q6/R6	Not Applicable

## Encoder and Decoder Pairs CMOS

These devices are designed to be used as encoder/decoder pairs in remote control applications.

The MC145026 encodes nine lines of information and serially sends this information upon receipt of a transmit enable ( $\overline{TE}$ ) signal. The nine lines may be encoded with trinary data (low, high, or open) or binary data (low or high). The words are transmitted twice per encoding sequence to increase security.

The MC145027 decoder receives the serial stream and interprets five of the trinary digits as an address code. Thus, 243 addresses are possible. If binary data is used at the encoder, 32 addresses are possible. The remaining serial information is interpreted as four bits of binary data. The valid transmission (VT) output goes high on the MC145027 when two conditions are met. First, two addresses must be consecutively received (in one encoding sequence) which both match the local address. Second, the 4 bits of data must match the last valid data received. The active VT indicates that the information at the Data output pins has been updated.

The MC145028 decoder treats all nine trinary digits as an address which allows 19,683 codes. If binary data is encoded, 512 codes are possible. The VT output goes high on the MC145028 when two addresses are consecutively received (in one encoding sequence) which both match the local address.

- Operating Temperature Range:  $-40$  to  $+85^{\circ}\text{C}$
- Very-Low Standby Current for the Encoder: 300 nA Maximum @  $25^{\circ}\text{C}$
- Interfaces with RF, Ultrasonic, or Infrared Modulators and Demodulators
- RC Oscillator, No Crystal Required
- High External Component Tolerance; Can Use  $\pm 5\%$  Components

## OPERATING CHARACTERISTICS

### MC145026

The encoder serially transmits trinary data as defined by the state of the A1 – A5 and A6/D6 – A9/D9 input pins. These pins may be in either of three states (low, high, or open) allowing 19,683 possible codes. The transmit sequence is initiated by a low level on the  $\overline{TE}$  input pin. Upon power-up, the MC145026 can continuously transmit as long as  $\overline{TE}$  remains low (also, the device can transmit two-word sequences by pulsing  $\overline{TE}$  low). However, no MC145026 application should be designed to rely upon the first data word transmitted immediately after power-up because this word may be invalid. Between the two data words, no signal is sent for three data periods (see Figure 10).

Each transmitted trinary digit is encoded into pulses (see Figure 11). A logic 0 (low) is encoded as two consecutive short pulses, a logic 1 (high) as two consecutive long pulses, and an open (high impedance) as a long pulse followed by a short pulse. The input state is determined by using a weak “output” device to try to force each input high then low. If only a high state results from the two tests, the input is assumed to be hardwired to  $V_{DD}$ . If only a low state is obtained, the input is assumed to be hardwired to  $V_{SS}$ . If both a high and a low can be forced at an input, an open is assumed and is encoded as such. The “high” and “low” levels are 70% and 30% of the supply voltage as shown in the Electrical Characteristics table. The weak “output” device sinks/sources up to 110  $\mu$ A at a 5 V supply level, 500  $\mu$ A at 10 V, and 1 mA at 15 V.

The  $\overline{TE}$  input has an internal pull-up device so that a simple switch may be used to force the input low. While  $\overline{TE}$  is high and the second-word transmission has timed out, the encoder is completely disabled, the oscillator is inhibited, and the current drain is reduced to quiescent current. When  $\overline{TE}$  is brought low, the oscillator is started and the transmit sequence begins. The inputs are then sequentially selected, and determinations are made as to the input logic states. This information is serially transmitted via the  $D_{Out}$  pin.

### MC145027

This decoder receives the serial data from the encoder and outputs the data, if it is valid. The transmitted data, consisting of two identical words, is examined bit by bit during reception. The first five trinary digits are assumed to be the address. If the received address matches the local address, the next four (data) bits are internally stored, but are not transferred to the output data latch. As the second encoded word is received, the address must again match. If a match occurs, the new data bits are checked against the previously stored data bits. If the two nibbles of data (four bits each) match, the data is transferred to the output data latch by VT and remains until new data replaces it. At the same time, the VT output pin is brought high and remains high until an error is received or until no input signal is received for four data periods (see Figure 10).

Although the address information may be encoded in trinary, the data information must be either a 1 or 0. A trinary (open) data line is decoded as a logic 1.

### MC145028

This decoder operates in the same manner as the MC145027 except that nine address lines are used and no data output is available. The VT output is used to indicate that a valid address has been received. For transmission security, two identical transmitted words must be consecutively received before a VT output signal is issued.

The MC145028 allows 19,683 addresses when trinary levels are used. 512 addresses are possible when binary levels are used.

## PIN DESCRIPTIONS

### MC145026 ENCODER

#### A1 – A5, A6/D6 – A9/D9

#### Address, Address/Data Inputs (Pins 1 – 7, 9, and 10)

These address/data inputs are encoded and the data is sent serially from the encoder via the  $D_{Out}$  pin.

#### RS, CTC, RTC

#### (Pins 11, 12, and 13)

These pins are part of the oscillator section of the encoder (see Figure 9).

If an external signal source is used instead of the internal oscillator, it should be connected to the  $R_S$  input and the  $R_{TC}$  and  $C_{TC}$  pins should be left open.

#### $\overline{TE}$

#### Transmit Enable (Pin 14)

This active-low transmit enable input initiates transmission when forced low. An internal pull-up device keeps this input normally high. The pull-up current is specified in the Electrical Characteristics table.

#### $D_{Out}$

#### Data Out (Pin 15)

This is the output of the encoder that serially presents the encoded data word.

#### $V_{SS}$

#### Negative Power Supply (Pin 8)

The most-negative supply potential. This pin is usually ground.

#### $V_{DD}$

#### Positive Power Supply (Pin 16)

The most-positive power supply pin.

### MC145027 AND MC145028 DECODERS

#### A1 – A5, A1 – A9

#### Address Inputs (Pins 1 – 5) — MC145027,

#### Address Inputs (Pins 1 – 5, 15, 14, 13, 12) — MC145028

These are the local address inputs. The states of these pins must match the appropriate encoder inputs for the VT pin to go high. The local address may be encoded with trinary or binary data.

#### D6 – D9

#### Data Outputs (Pins 15, 14, 13, 12) — MC145027 Only

These outputs present the binary information that is on encoder inputs A6/D6 through A9/D9. Only binary data is

acknowledged; a trinary open at the MC145026 encoder is decoded as a high level (logic 1).

**D<sub>in</sub>**  
**Data In (Pin 9)**

This pin is the serial data input to the decoder. The input voltage must be at CMOS logic levels. The signal source driving this pin must be dc coupled.

**R<sub>1</sub>, C<sub>1</sub>**  
**Resistor 1, Capacitor 1 (Pins 6, 7)**

As shown in Figures 2 and 3, these pins accept a resistor and capacitor that are used to determine whether a narrow pulse or wide pulse has been received. The time constant  $R_1 \times C_1$  should be set to 1.72 encoder clock periods:

$$R_1 C_1 = 3.95 R_{TC} C_{TC}$$

**R<sub>2</sub>/C<sub>2</sub>**  
**Resistor 2/Capacitor 2 (Pin 10)**

As shown in Figures 2 and 3, this pin accepts a resistor and capacitor that are used to detect both the end of a received word and the end of a transmission. The time constant  $R_2 \times C_2$  should be 33.5 encoder clock periods (four data periods per Figure 11):  $R_2 C_2 = 77 R_{TC} C_{TC}$ . This time

constant is used to determine whether the D<sub>in</sub> pin has remained low for four data periods (end of transmission). A separate on-chip comparator looks at the voltage-equivalent two data periods ( $0.4 R_2 C_2$ ) to detect the dead time between received words within a transmission.

**VT**  
**Valid Transmission Output (Pin 11)**

This valid transmission output goes high after the second word of an encoding sequence when the following conditions are satisfied:

1. the received addresses of both words match the local decoder address, and
2. the received data bits of both words match.

VT remains high until either a mismatch is received or no input signal is received for four data periods.

**V<sub>SS</sub>**  
**Negative Power Supply (Pin 8)**

The most-negative supply potential. This pin is usually ground.

**V<sub>DD</sub>**  
**Positive Power Supply (Pin 16)**

The most-positive power supply pin.

This oscillator operates at a frequency determined by the external RC network; i.e.,

$$f \approx \frac{1}{2.3 R_{TC} C_{TC'}} \text{ (Hz)}$$

for  $1 \text{ kHz} \leq f \leq 400 \text{ kHz}$

where:  $C_{TC'} = C_{TC} + C_{\text{layout}} + 12 \text{ pF}$

$R_S \approx 2 R_{TC}$

$R_S \geq 20 \text{ k}$

$R_{TC} \geq 10 \text{ k}$

$400 \text{ pF} < C_{TC} < 15 \text{ }\mu\text{F}$

The value for  $R_S$  should be chosen to be  $\geq 2$  times  $R_{TC}$ . This range ensures that current through  $R_S$  is insignificant compared to current through  $R_{TC}$ . The upper limit for  $R_S$  must ensure that  $R_S \times 5 \text{ pF}$  (input capacitance) is small compared to  $R_{TC} \times C_{TC}$ .

For frequencies outside the indicated range, the formula is less accurate. The minimum recommended oscillation frequency of this circuit is 1 kHz. Susceptibility to externally induced noise signals may occur for frequencies below 1 kHz and/or when resistors utilized are greater than 1 M $\Omega$ .

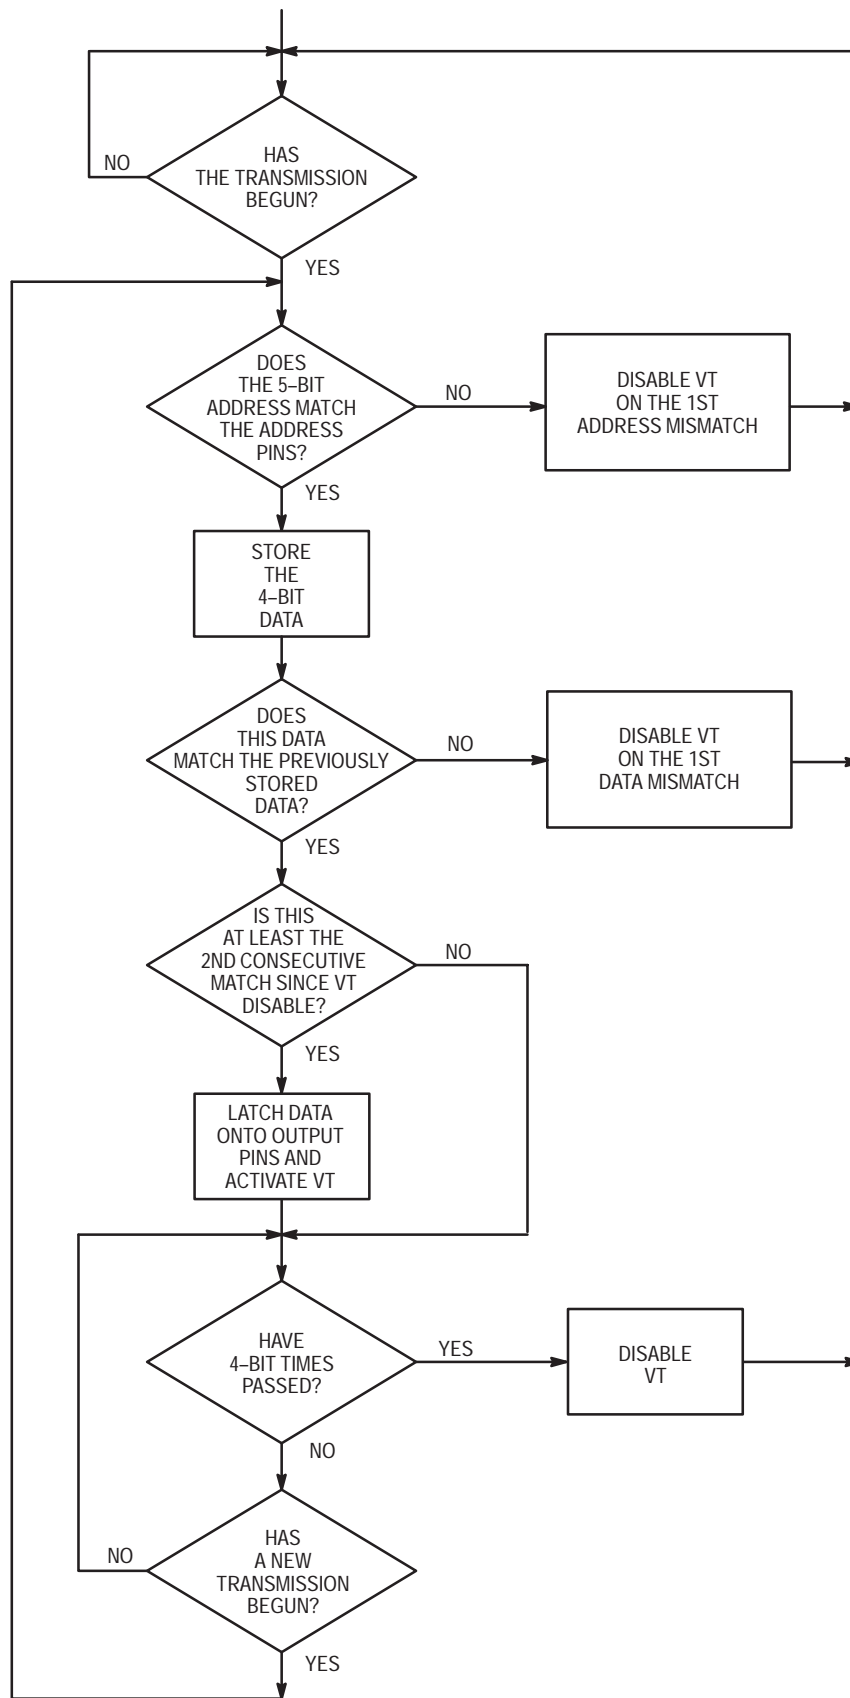

Figure 13. MC145027 Flowchart

Figure 14. MC145028 Flowchart

## MC145027 AND MC145028 TIMING

To verify the MC145027 or MC145028 timing, check the waveforms on C1 (Pin 7) and R2/C2 (Pin 10) as compared to the incoming data waveform on  $D_{in}$  (Pin 9).

The R–C decay seen on C1 discharges down to  $1/3 V_{DD}$  before being reset to  $V_{DD}$ . This point of reset (labelled “DOS” in Figure 15) is the point in time where the decision is made whether the data seen on  $D_{in}$  is a 1 or 0. DOS should not be too close to the  $D_{in}$  data edges or intermittent operation may occur.

The other timing to be checked on the MC145027 and MC145028 is on R2/C2 (see Figure 16). The R–C decay is continually reset to  $V_{DD}$  as data is being transmitted. Only between words and after the end-of-transmission (EOT) does R2/C2 decay significantly from  $V_{DD}$ . R2/C2 can be used to identify the internal end-of-word (EOW) timing edge which is generated when R2/C2 decays to  $2/3 V_{DD}$ . The internal EOT timing edge occurs when R2/C2 decays to  $1/3 V_{DD}$ . When the waveform is being observed, the R–C decay should go down between the  $2/3$  and  $1/3 V_{DD}$  levels, but not too close to either level before data transmission on  $D_{in}$  resumes.

Verification of the timing described above should ensure a good match between the MC145026 transmitter and the MC145027 and MC145028 receivers.

**Figure 17. Typical Application**

## APPLICATIONS INFORMATION

### INFRARED TRANSMITTER

In Figure 18, the MC145026 encoder is set to run at an oscillator frequency of about 4 to 9 kHz. Thus, the time required for a complete two-word encoding sequence is about 20 to 40 ms. The data output from the encoder gates an RC oscillator running at 50 kHz; the oscillator shown starts rapidly enough to be used in this application. When the "send" button is not depressed, both the MC145026 and oscillator are in a low-power standby state. The RC oscillator has to be trimmed for 50 kHz and has some drawbacks for frequency stability. A superior system uses a ceramic resonator oscillator running at 400 kHz. This oscillator feeds a divider as shown in Figure 19. The unused inputs of the MC14011UB must be grounded.

The MLED81 IRED is driven with the 50 kHz square wave at about 200 to 300 mA to generate the carrier. If desired, two IREDs wired in series can be used (see Application Note AN1016 for more information). The bipolar IRED switch, shown in Figure 18, offers two advantages over a FET. First, a logic FET has too much gate capacitance for the MC14011UB to drive without waveform distortion. Second, the bipolar drive permits lower supply voltages, which are an advantage in portable battery-powered applications.

The configuration shown in Figure 18 operates over a supply range of 4.5 to 18 V. A low-voltage system which operates down to 2.5 V could be realized if the oscillator section of a MC74HC4060 is used in place of the MC14011UB. The data output of the MC145026 is inverted and fed to the RESET pin of the MC74HC4060. Alternately, the MC74HCU04 could be used for the oscillator.

Information on the MC14011UB is in book number DL131/D. The MC74HCU04 and MC74HC4060 are found in book number DL129/D.

### INFRARED RECEIVER

The receiver in Figure 20 couples an IR-sensitive diode to input preamp A1, followed by band-pass amplifier A2 with a gain of about 10. Limiting stage A3 follows, with an output of about 800 mV p-p. The limited 50 kHz burst is detected by comparator A4 that passes only positive pulses, and peak-

detected and filtered by a diode/RC network to extract the data envelope from the burst. Comparator A5 boosts the signal to logic levels compatible with the MC145027/28 data input. The  $D_{in}$  pin of these decoders is a standard CMOS high-impedance input which must **not** be allowed to float. Therefore, direct coupling from A5 to the decoder input is utilized.

Shielding should be used on at least A1 and A2, with good ground and high-sensitivity circuit layout techniques applied.

For operation with supplies higher than +5 V, limiter A4's positive output swing needs to be limited to 3 to 5 V. This is accomplished via adding a zener diode in the negative feedback path, thus avoiding excessive system noise. The biasing resistor stack should be adjusted such that V3 is 1.25 to 1.5 V.

This system works up to a range of about 10 meters. The gains of the system may be adjusted to suit the individual design needs. The 100  $\Omega$  resistor in the emitter of the first 2N5088 and the 1 k $\Omega$  resistor feeding A2 may be altered if different gain is required. In general, more gain does not necessarily result in increased range. This is due to noise floor limitations. The designer should increase transmitter power and/or increase receiver aperture with Fresnel lensing to greatly improve range. See Application Note AN1016 for additional information.

Information on the MC34074 is in data book DL128/D.

### TRINARY SWITCH MANUFACTURERS

Midland Ross—Electronic Connector Div.  
Greyhill  
Augat/Alcoswitch  
Aries Electronics

The above companies may not have the switches in a DIP. For more information, call them or consult *eem Electronic Engineers Master Catalog* or the *Gold Book*. **Ask for SPDT with center OFF.**

Alternative: An SPST can be placed in series between a SPDT and the Encoder or Decoder to achieve trinary action.

Motorola cannot recommend one supplier over another and in no way suggests that this is a complete listing of trinary switch manufacturers.

# 10-Bit A/D Converter with Serial Interface CMOS

These ratiometric 10-bit ADCs have serial interface ports to provide communication with MCUs and MPUs. *Either a 10- or 16-bit format can be used.* The 16-bit format can be one continuous 16-bit stream or two intermittent 8-bit streams. The converters operate from a single power supply with no external trimming required. Reference voltages down to 4.0 V are accommodated.

The MC145050 has the same pin out as the 8-bit MC145040 which allows an external clock (ADCLK) to operate the dynamic A/D conversion sequence. The MC145051 has the same pin out as the 8-bit MC145041 which has an internal clock oscillator and an end-of-conversion (EOC) output.

- 11 Analog Input Channels with Internal Sample-and-Hold
- Operating Temperature Range: - 40 to 125° C
- Successive Approximation Conversion Time:
  - MC145050 — 21  $\mu$ s (with 2.1 MHz ADCLK)
  - MC145051 — 44  $\mu$ s Maximum
- Maximum Sample Rate: MC145050 — 38 ks/s  
MC145051 — 20.4 ks/s
- Analog Input Range with 5-Volt Supply: 0 to 5 V
- Monotonic with No Missing Codes
- Direct Interface to Motorola SPI and National MICROWIRE Serial Data Ports
- Digital Inputs/Outputs are TTL, NMOS, and CMOS Compatible
- Low Power Consumption: 14 mW
- Chip Complexity: 1630 Elements (FETs, Capacitors, etc.)
- See Application Note AN1062 for Operation with QSPI

## ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Value	Unit
V <sub>DD</sub>	DC Supply Voltage (Referenced to V <sub>SS</sub> )	- 0.5 to + 6.0	V
V <sub>ref</sub>	DC Reference Voltage	V <sub>AG</sub> to V <sub>DD</sub> + 0.1	V
V <sub>AG</sub>	Analog Ground	V <sub>SS</sub> - 0.1 to V <sub>ref</sub>	V
V <sub>in</sub>	DC Input Voltage, Any Analog or Digital Input	V <sub>SS</sub> - 0.5 to V <sub>DD</sub> + 0.5	V
V <sub>out</sub>	DC Output Voltage	V <sub>SS</sub> - 0.5 to V <sub>DD</sub> + 0.5	V
I <sub>in</sub>	DC Input Current, per Pin	± 20	mA
I <sub>out</sub>	DC Output Current, per Pin	± 25	mA
I <sub>DD</sub> , I <sub>SS</sub>	DC Supply Current, V <sub>DD</sub> and V <sub>SS</sub> Pins	± 50	mA
T <sub>stg</sub>	Storage Temperature	- 65 to 150	°C
T <sub>L</sub>	Lead Temperature, 1 mm from Case for 10 Seconds	260	°C

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V<sub>in</sub> and V<sub>out</sub> should be constrained to the range V<sub>SS</sub> ≤ (V<sub>in</sub> or V<sub>out</sub>) ≤ V<sub>DD</sub>.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V<sub>SS</sub> or V<sub>DD</sub>). Unused outputs must be left open.

\* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the Operation Ranges below..

## OPERATION RANGES (Applicable to Guaranteed Limits)

Symbol	Parameter	Value	Unit
V <sub>DD</sub>	DC Supply Voltage, Referenced to V <sub>SS</sub>	4.5 to 5.5	V
V <sub>ref</sub>	DC Reference Voltage	V <sub>AG</sub> + 4.0 to V <sub>DD</sub> + 0.1	V
V <sub>AG</sub>	Analog Ground	V <sub>SS</sub> - 0.1 to V <sub>ref</sub> - 4.0	V
V <sub>AI</sub>	Analog Input Voltage (See Note)	V <sub>AG</sub> to V <sub>ref</sub>	V
V <sub>in</sub> , V <sub>out</sub>	Digital Input Voltage, Output Voltage	V <sub>SS</sub> to V <sub>DD</sub>	V
T <sub>A</sub>	Ambient Operating Temperature	- 40 to 125	°C

NOTE: Analog input voltages greater than V<sub>ref</sub> convert to full scale. Input voltages less than V<sub>AG</sub> convert to zero. See V<sub>ref</sub> and V<sub>AG</sub> pin descriptions.

—	$C_{out}$	Maximum Three-State Output Capacitance $D_{out}$	15	pF

### NOTES:

- After the 10th SCLK falling edge ( $\leq 2$  V), at least 1 SCLK rising edge ( $\geq 2$  V) must occur within 38 ADCLKs (MC145050) or 18.5  $\mu$ s (MC145051).
- On the MC145051, a  $\overline{CS}$  edge may be received immediately after an active transition on the EOC pin.

## PIN DESCRIPTIONS

### DIGITAL INPUTS AND OUTPUT

The various serial bit-stream formats for the MC145050/51 are illustrated in the timing diagrams of Figures 9 through 14. Table 1 assists in selection of the appropriate diagram. Note that the ADCs accept 16 clocks which makes them SPI (Serial Peripheral Interface) compatible.

**Table 1. Timing Diagram Selection**

No. of Clocks in Serial Transfer	Using $\overline{CS}$	Serial Transfer Interval	Figure No.
10	Yes	Don't Care	9
10	No	Don't Care	10
11 to 16	Yes	Shorter than Conversion	11
16	No	Shorter than Conversion	12
11 to 16	Yes	Longer than Conversion	13
16	No	Longer than Conversion	14

### $\overline{CS}$

#### Active-Low Chip Select Input (Pin 15)

Chip select initializes the chip to perform conversions and provides 3-state control of the data output pin ( $D_{OUT}$ ). While inactive high,  $\overline{CS}$  forces  $D_{OUT}$  to the high-impedance state and disables the data input ( $D_{IN}$ ) and serial clock (SCLK) pins. A high-to-low transition on  $\overline{CS}$  resets the serial data port and synchronizes it to the MPU data stream.  $\overline{CS}$  can remain active during the conversion cycle and can stay in the active low state for multiple serial transfers or  $\overline{CS}$  can be inactive high after each transfer. If  $\overline{CS}$  is kept active low between transfers, the length of each transfer is limited to either 10 or 16 SCLK cycles. If  $\overline{CS}$  is in the inactive high state between transfers, each transfer can be anywhere from 10 to 16 SCLK cycles long. See the SCLK pin description for a more detailed discussion of these requirements.

On the MC145050/51 spurious chip selects caused by system noise are minimized by the internal circuitry.

Any transitions on the MC145050  $\overline{CS}$  pin are recognized as valid only if the level is maintained for a setup time plus two falling edges of ADCLK after the transition.

Transitions on the MC145051  $\overline{CS}$  pin are recognized as valid only if the level is maintained for about 2  $\mu$ s after the transition.

#### NOTE

If  $\overline{CS}$  is inactive high after the 10th SCLK cycle and then goes active low before the A/D conversion is complete, the conversion is aborted and the chip enters the initial state, ready for another serial transfer/conversion sequence. At this point, the output data register contains the result from the conversion before the aborted conversion. Note that the last step of the A/D conversion sequence is to update the output data register with the result. Therefore, if  $\overline{CS}$  goes active low in an attempt to abort the conversion too close to the end of the conversion sequence, the result register may be corrupted and the chip could be thrown out of sync with the processor until  $\overline{CS}$  is toggled again (refer to the AC Electrical Characteristics in the spec tables).

### $D_{OUT}$

#### Serial Data Output of the A/D Conversion Result (Pin 16)

This output is in the high-impedance state when  $\overline{CS}$  is inactive high. When the chip recognizes a valid active low on  $\overline{CS}$ ,  $D_{OUT}$  is taken out of the high-impedance state and is driven with the MSB of the previous conversion result. (For the first transfer after power-up, data on  $D_{OUT}$  is undefined for the entire transfer.) The value on  $D_{OUT}$  changes to the second most significant result bit upon the first falling edge of SCLK. The remaining result bits are shifted out in order, with the LSB appearing on  $D_{OUT}$  upon the ninth falling edge of SCLK. Note that the order of the transfer is MSB to LSB. Upon the 10th falling edge of SCLK,  $D_{OUT}$  is immediately driven low (if allowed by  $\overline{CS}$ ) so that transfers of more than 10 SCLKs read zeroes as the unused LSBs.

When  $\overline{CS}$  is held active low between transfers,  $D_{OUT}$  is driven from a low level to the MSB of the conversion result for three cases: Case 1 — upon the 16th SCLK falling edge if the transfer is longer than the conversion time (Figure 14); Case 2 — upon completion of a conversion for a 16-bit transfer interval shorter than the conversion (Figure 12); Case 3 — upon completion of a conversion for a 10-bit transfer (Figure 10).

### $D_{IN}$

#### Serial Data Input (Pin 17)

The four-bit serial input stream begins with the MSB of the analog mux address (or the user test mode) that is to be converted next. The address is shifted in on the first four rising edges of SCLK. After the four mux address bits have been received, the data on  $D_{IN}$  is ignored for the remainder of the present serial transfer. See Table 2 in **Applications Information**.

### SCLK

#### Serial Data Clock (Pin 18)

This clock input drives the internal I/O state machine to perform three major functions: (1) drives the data shift registers to simultaneously shift in the next mux address from the  $D_{IN}$  pin and shift out the previous conversion result on the  $D_{OUT}$  pin, (2) begins sampling the analog voltage onto the RC DAC as soon as the new mux address is available, and (3) transfers control to the A/D conversion state machine (driven by ADCLK) after the last bit of the previous conversion result has been shifted out on the  $D_{OUT}$  pin.

The serial data shift registers are completely static, allowing SCLK rates down to the dc. There are some cases, however, that require a minimum SCLK frequency as discussed later in this section. SCLK need not be synchronous to ADCLK. At least ten SCLK cycles are required for each simultaneous data transfer. If the 16-bit format is used, SCLK can be one continuous 16-bit stream or two intermittent 8-bit streams. After the serial port has been initiated to perform a serial transfer\*, the new mux address is shifted in on the first

\* The serial port can be initiated in three ways: (1) a recognized  $\overline{CS}$  falling edge, (2) the end of an A/D conversion if the port is performing either a 10-bit or a 16-bit "shorter-than-conversion" transfer with  $\overline{CS}$  active low between transfers, and (3) the 16th falling edge of SCLK if the port is performing 16-bit "longer-than-conversion" transfers with  $\overline{CS}$  active low between transfers.

four rising edges of SCLK, and the previous 10-bit conversion result is shifted out on the first nine falling edges of SCLK. After the fourth rising edge of SCLK, the new mux address is available; therefore, on the next edge of SCLK (the fourth falling edge), the analog input voltage on the selected mux input begins charging the RC DAC and continues to do so until the tenth falling edge of SCLK. After this tenth SCLK edge, the analog input voltage is disabled from the RC DAC and the RC DAC begins the “hold” portion of the A/D conversion sequence. Also upon this tenth SCLK edge, control of the internal circuitry is transferred to ADCLK which drives the successive approximation logic to complete the conversion. If 16 SCLK cycles are used during each transfer, then there is a constraint on the minimum SCLK frequency. Specifically, there must be at least one rising edge on SCLK before the A/D conversion is complete. If the SCLK frequency is too low and a rising edge does not occur during the conversion, the chip is thrown out of sync with the processor and  $\overline{CS}$  needs to be toggled in order to restore proper operation. If 10 SCLKs are used per transfer, then there is no lower frequency limit on SCLK. Also note that if the ADC is operated such that  $\overline{CS}$  is inactive high between transfers, then the number of SCLK cycles per transfer can be anything between 10 and 16 cycles, but the “rising edge” constraint is still in effect if more than 10 SCLKs are used. (If  $\overline{CS}$  stays active low for multiple transfers, the number of SCLK cycles must be either 10 or 16.)

#### **ADCLK** **A/D Conversion Clock Input (Pin 19, MC145050 Only)**

This pin clocks the dynamic A/D conversion sequence, and may be asynchronous to SCLK. Control of the chip passes to ADCLK after the tenth falling edge of SCLK. Control of the chip is passed back to SCLK after the successive approximation conversion sequence is complete (44 ADCLK cycles), or after a valid chip select is recognized. ADCLK also drives the  $\overline{CS}$  recognition logic. The chip ignores transitions on  $\overline{CS}$  unless the state remains for a setup time plus two falling edges of ADCLK. The source driving ADCLK must be free running.

#### **EOC** **End-of-Conversion Output (Pin 19, MC145051 Only)**

EOC goes low on the tenth falling edge of SCLK. A low-to-high transition on EOC occurs when the A/D conversion is complete and the data is ready for transfer.

### **ANALOG INPUTS AND TEST MODE**

#### **AN0 through AN10** **Analog Multiplexer Inputs (Pins 1 – 9, 11, 12)**

The input AN0 is addressed by loading \$0 into the mux address register. AN1 is addressed by \$1, AN2 by \$2, ..., AN10

by \$A. Table 2 shows the input format for a 16-bit stream. The mux features a break-before-make switching structure to minimize noise injection into the analog inputs. The source resistance driving these inputs must be  $\leq 1\text{ k}\Omega$ .

During normal operation, leakage currents through the analog mux from unselected channels to a selected channel and leakage currents through the ESD protection diodes on the selected channel occur. These leakage currents cause an offset voltage to appear across any series source resistance on the selected channel. Therefore, any source resistance greater than  $1\text{ k}\Omega$  (Motorola test condition) may induce errors in excess of guaranteed specifications.

There are three tests available that verify the functionality of all the control logic as well as the successive approximation comparator. These tests are performed by addressing \$B, \$C, or \$D and they convert a voltage of  $(V_{\text{ref}} + V_{\text{AG}})/2$ ,  $V_{\text{AG}}$ , or  $V_{\text{ref}}$ , respectively. The voltages are obtained internally by sampling  $V_{\text{ref}}$  or  $V_{\text{AG}}$  onto the appropriate elements of the RC DAC during the sample phase. Addressing \$B, \$C, or \$D produces an output of \$200 (half scale), \$000, or \$3FF (full scale), respectively, if the converter is functioning properly. However, deviation from these values occurs in the presence of sufficient system noise (external to the chip) on  $V_{\text{DD}}$ ,  $V_{\text{SS}}$ ,  $V_{\text{ref}}$ , or  $V_{\text{AG}}$ .

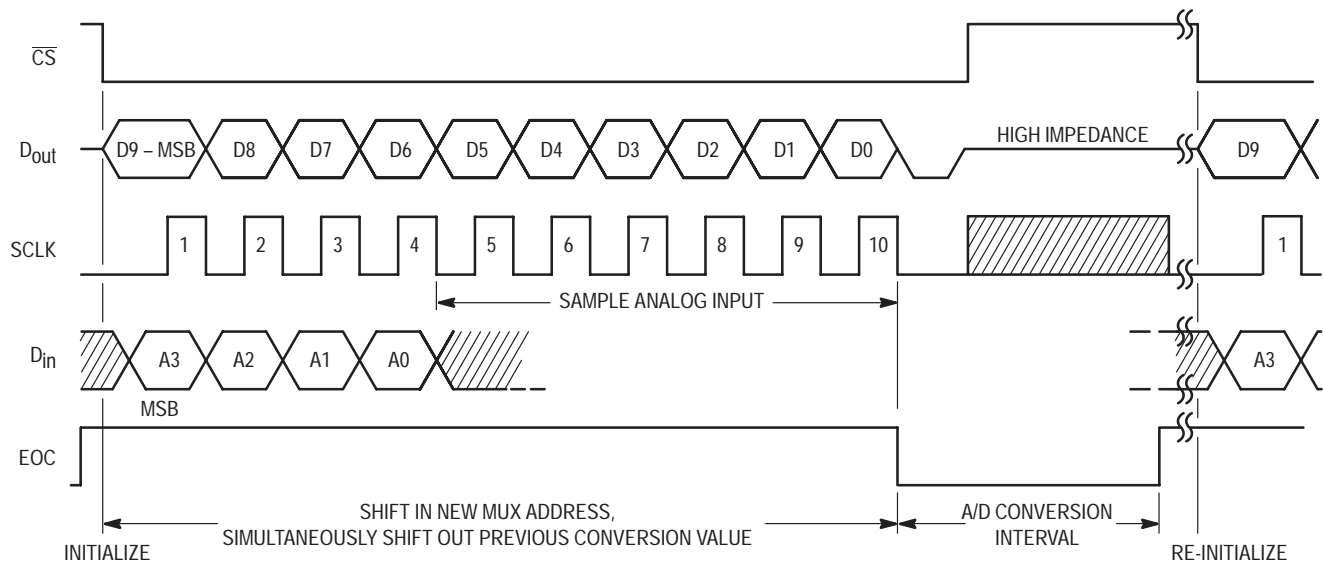

### **POWER AND REFERENCE PINS**

#### **$V_{\text{SS}}$ and $V_{\text{DD}}$** **Device Supply Pins (Pins 10 and 20)**

$V_{\text{SS}}$  is normally connected to digital ground;  $V_{\text{DD}}$  is connected to a positive digital supply voltage. Low frequency ( $V_{\text{DD}} - V_{\text{SS}}$ ) variations over the range of 4.5 to 5.5 volts do not affect the A/D accuracy. (See the Operations Ranges Table for restrictions on  $V_{\text{ref}}$  and  $V_{\text{AG}}$  relative to  $V_{\text{DD}}$  and  $V_{\text{SS}}$ .) Excessive inductance in the  $V_{\text{DD}}$  or  $V_{\text{SS}}$  lines, as on automatic test equipment, may cause A/D offsets  $> \pm 1\text{ LSB}$ . Use of a  $0.1\text{ }\mu\text{F}$  bypass capacitor across these pins is recommended.

#### **$V_{\text{AG}}$ and $V_{\text{ref}}$** **Analog Reference Voltage Pins (Pins 13 and 14)**

Analog reference voltage pins which determine the lower and upper boundary of the A/D conversion. Analog input voltages  $\geq V_{\text{ref}}$  produce a full scale output and input voltages  $\leq V_{\text{AG}}$  produce an output of zero. CAUTION: The analog input voltage must be  $\geq V_{\text{SS}}$  and  $\leq V_{\text{DD}}$ . The A/D conversion result is ratiometric to  $V_{\text{ref}} - V_{\text{AG}}$ .  $V_{\text{ref}}$  and  $V_{\text{AG}}$  must be as noise-free as possible to avoid degradation of the A/D conversion. Ideally,  $V_{\text{ref}}$  and  $V_{\text{AG}}$  should be single-point connected to the voltage supply driving the system's transducers. Use of a  $0.22\text{ }\mu\text{F}$  bypass capacitor across these pins is strongly urged.

Figure 14. Timing for 16-Clock Transfer Not Using  $\overline{CS}^*$  (Serial Transfer Interval Longer Than Conversion)

NOTES:

- D9, D8, D7, . . . , D0 = the result of the previous A/D conversion.
- A3, A2, A1, A0 = the mux address for the next A/D conversion.

\*NOTES:

1. This figure illustrates the behavior of the MC145051. The MC145050 behaves identically except there is no EOC signal and the conversion time is 44 ADCLK cycles (user-controlled time).
2. The 11th SCLK rising edge must occur before the conversion is complete. Otherwise the serial port is thrown out of sync with the microprocessor for the remainder of the transfer.

## APPLICATIONS INFORMATION

### DESCRIPTION

This example application of the MC145050/MC145051 ADCs interfaces three controllers to a microprocessor and processes data in real-time for a video game. The standard joystick X-axis (left/right) and Y-axis (up/down) controls as well as engine thrust controls are accommodated.

Figure 15 illustrates how the MC145050/MC145051 is used as a cost-effective means to simplify this type of circuit design. Utilizing one ADC, three controllers are interfaced to a CMOS or NMOS microprocessor with a serial peripheral interface (SPI) port. Processors with National Semiconductor's MICROWIRE serial port may also be used. Full duplex operation optimizes throughput for this system.

### DIGITAL DESIGN CONSIDERATIONS

Motorola's MC68HC05C4 CMOS MCU may be chosen to reduce power supply size and cost. The NMOS MCUs may be used if power consumption is not critical. A  $V_{DD}$  or  $V_{SS}$  0.1  $\mu$ F bypass capacitor should be closely mounted to the ADC.

Both the MC145050 and MC145051 accommodate all the analog system inputs. The MC145050, when used with a 2 MHz MCU, takes 27  $\mu$ s to sample the analog input, perform the conversion, and transfer the serial data at 2 MHz. Forty-four ADCLK cycles (2 MHz at input pin 19) must be provided and counted by the MCU before reading the ADC results. The MC145051 has the end-of-conversion (EOC) signal (at output pin 19) to define when data is ready, but has a slower 49  $\mu$ s cycle time. However, the 49  $\mu$ s is constant for serial data rates of 2 MHz independent of the MCU clock frequency. Therefore, the MC145051 may be used with the CMOS MCU operating at reduced clock rates to minimize power consumption without severely sacrificing ADC cycle times, with EOC being used to generate an interrupt. (The MC145051 may also be used with MCUs which do not provide a system clock.)

### ANALOG DESIGN CONSIDERATIONS

Controllers with output impedances of less than 1 k $\Omega$  may be directly interfaced to these ADCs, eliminating the need for buffer amplifiers. Separate lines connect the  $V_{ref}$  and  $V_{AG}$  pins on the ADC with the controllers to provide isolation from system noise.

Although not indicated in Figure 15, the  $V_{ref}$  and controller output lines may need to be shielded, depending on their

length and electrical environment. This should be verified during prototyping with an oscilloscope. If shielding is required, a twisted pair or foil-shielded wire (not coax) is appropriate for this low frequency application. One wire of the pair or the shield must be  $V_{AG}$ .

A reference circuit voltage of 5 volts is used for this application. The reference circuitry may be as simple as tying  $V_{AG}$  to system ground and  $V_{ref}$  to the system's positive supply. (See Figure 16.) However, the system power supply noise may require that a separate supply be used for the voltage reference. This supply must provide source current for  $V_{ref}$  as well as current for the controller potentiometers.

A bypass capacitor of approximately 0.22  $\mu$ F across the  $V_{ref}$  and  $V_{AG}$  pins is recommended. These pins are adjacent on the ADC package which facilitates mounting the capacitor very close to the ADC.

### SOFTWARE CONSIDERATIONS

The software flow for acquisition is straightforward. The nine analog inputs, AN0 through AN8, are scanned by reading the analog value of the previously addressed channel into the MCU and sending the address of the next channel to be read to the ADC, simultaneously.

If the design is realized using the MC145050, 44 ADCLK cycles (at pin 19) must be counted by the MCU to allow time for A/D conversion. The designer utilizing the MC145051 has the end-of-conversion signal (at pin 19) to define the conversion interval. EOC may be used to generate an interrupt, which is serviced by reading the serial data from the ADC. The software flow should then process and format the data, and transfer the information to the video circuitry for updating the display.

When these ADCs are used with a 16-bit (2-byte) transfer, there are two types of offsets involved. In the first type of offset, the channel information sent to the ADCs is offset by 12 bits. That is, in the 16-bit stream, only the first 4 bits (4 MSBs) contain the channel information. The balance of the bits are don't cares. This results in 3 don't-care nibbles, as shown in Table 2. The second type of offset is in the conversion result returned from the ADCs; this is offset by 6 bits. In the 16-bit stream, the first 10 bits (10 MSBs) contain the conversion results. The last 6 bits are zeroes. The hexadecimal result is shown in the first column of Table 3. The second column shows the result after the offset is removed by a microprocessor routine. If the 16-bit format is used, these ADCs can transfer one continuous 16-bit stream or two intermittent 8-bit streams.

# 10-Bit A/D Converter with Serial Interface

## CMOS

This ratiometric 10-bit ADC has a serial interface port to provide communication with MCUs and MPUs. *Either a 10- or 16-bit format can be used.* The 16-bit format can be one continuous 16-bit stream or two intermittent 8-bit streams. The converter operates from a single power supply with no external trimming required. Reference voltages down to 4.0 V are accommodated.

The MC145053 has an internal clock oscillator to operate the dynamic A/D conversion sequence and an end-of-conversion (EOC) output.

- 5 Analog Input Channels with Internal Sample-and-Hold
- Operating Temperature Range: - 40 to 125° C
- Successive Approximation Conversion Time: 44 μs Maximum
- Maximum Sample Rate: 20.4 ks/s
- Analog Input Range with 5-Volt Supply: 0 to 5 V
- Monotonic with No Missing Codes
- Direct Interface to Motorola SPI and National MICROWIRE Serial Data Ports
- Digital Inputs/Outputs are TTL, NMOS, and CMOS Compatible
- Low Power Consumption: 14 mW
- Chip Complexity: 1630 Elements (FETs, Capacitors, etc.)
- See Application Note AN1062 for Operation with QSPI

### BLOCK DIAGRAM

## MAXIMUM RATINGS\*

Symbol	Parameter	Value	Unit
V <sub>DD</sub>	DC Supply Voltage (Referenced to V <sub>SS</sub> )	- 0.5 to + 6.0	V
V <sub>ref</sub>	DC Reference Voltage	V <sub>AG</sub> to V <sub>DD</sub> + 0.1	V
V <sub>AG</sub>	Analog Ground	V <sub>SS</sub> - 0.1 to V <sub>ref</sub>	V
V <sub>in</sub>	DC Input Voltage, Any Analog or Digital Input	V <sub>SS</sub> - 0.5 to V <sub>DD</sub> + 0.5	V
V <sub>out</sub>	DC Output Voltage	V <sub>SS</sub> - 0.5 to V <sub>DD</sub> + 0.5	V
I <sub>in</sub>	DC Input Current, per Pin	± 20	mA
I <sub>out</sub>	DC Output Current, per Pin	± 25	mA
I <sub>DD</sub> , I <sub>SS</sub>	DC Supply Current, V <sub>DD</sub> and V <sub>SS</sub> Pins	± 50	mA
T <sub>stg</sub>	Storage Temperature	- 65 to 150	°C
T <sub>L</sub>	Lead Temperature, 1 mm from Case for 10 Seconds	260	°C

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V<sub>in</sub> and V<sub>out</sub> should be constrained to the range V<sub>SS</sub> ≤ (V<sub>in</sub> or V<sub>out</sub>) ≤ V<sub>DD</sub>.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V<sub>SS</sub> or V<sub>DD</sub>). Unused outputs must be left open.

\* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the Operation Ranges below..

## OPERATION RANGES (Applicable to Guaranteed Limits)

Symbol	Parameter	Value	Unit
V <sub>DD</sub>	DC Supply Voltage, Referenced to V <sub>SS</sub>	4.5 to 5.5	V
V <sub>ref</sub>	DC Reference Voltage	V <sub>AG</sub> + 4.0 to V <sub>DD</sub> + 0.1	V
V <sub>AG</sub>	Analog Ground	V <sub>SS</sub> - 0.1 to V <sub>ref</sub> - 4.0	V
V <sub>AI</sub>	Analog Input Voltage (See Note)	V <sub>AG</sub> to V <sub>ref</sub>	V
V <sub>in</sub> , V <sub>out</sub>	Digital Input Voltage, Output Voltage	V <sub>SS</sub> to V <sub>DD</sub>	V
T <sub>A</sub>	Ambient Operating Temperature	- 40 to 125	°C

NOTE: Analog input voltages greater than V<sub>ref</sub> convert to full scale. Input voltages less than V<sub>AG</sub> convert to zero. See V<sub>ref</sub> and V<sub>AG</sub> pin descriptions.

## DC ELECTRICAL CHARACTERISTICS

(Voltages Referenced to V<sub>SS</sub>, Full Temperature and Voltage Ranges per Operation Ranges Table, unless otherwise indicated)

Symbol	Parameter	Test Condition	Guaranteed Limit	Unit
V <sub>IH</sub>	Minimum High-Level Input Voltage (D <sub>in</sub> , SCLK, $\overline{CS}$ )		2.0	V

I <sub>DD</sub>	Maximum Power Supply Current	V <sub>in</sub> = V <sub>SS</sub> or V <sub>DD</sub> , All Outputs Open	2.5	mA
I <sub>ref</sub>	Maximum Static Analog Reference Current (V <sub>ref</sub> )	V <sub>ref</sub> = V <sub>DD</sub> , V <sub>AG</sub> = V <sub>SS</sub>	100	μA
I <sub>AI</sub>	Maximum Analog Mux Input Leakage Current between all deselected inputs and any selected input (AN0 - AN4)	V <sub>AI</sub> = V <sub>SS</sub> to V <sub>DD</sub>	± 1	μA

## A/D CONVERTER ELECTRICAL CHARACTERISTICS

(Full Temperature and Voltage Ranges per Operation Ranges Table)

Characteristic	Definition and Test Conditions	Guaranteed Limit	Unit
Resolution	Number of bits resolved by the A/D converter	10	Bits
Maximum Nonlinearity	Maximum difference between an ideal and an actual ADC transfer function	$\pm 1$	LSB
Maximum Zero Error	Difference between the maximum input voltage of an ideal and an actual ADC for zero output code	$\pm 1$	LSB
Maximum Full-Scale Error	Difference between the minimum input voltage of an ideal and an actual ADC for full-scale output code	$\pm 1$	LSB
Maximum Total Unadjusted Error	Maximum sum of nonlinearity, zero error, and full-scale error	$\pm 1$	LSB
Maximum Quantization Error	Uncertainty due to converter resolution	$\pm 1/2$	LSB
Absolute Accuracy	Difference between the actual input voltage and the full-scale weighted equivalent of the binary output code, all error sources included	$\pm 1-1/2$	LSB
Maximum Conversion Time	Total time to perform a single analog-to-digital conversion	44	$\mu\text{s}$
Data Transfer Time	Total time to transfer digital serial data into and out of the device	10 to 16	SCLK cycles
Sample Acquisition Time	Analog input acquisition time window	6	SCLK cycles
Minimum Total Cycle Time	Total time to transfer serial data, sample the analog input, and perform the conversion; SCLK = 2.1 MHz	49	$\mu\text{s}$
Maximum Sample Rate	Rate at which analog inputs may be sampled; SCLK = 2.1 MHz	20.4	ks/s

## AC ELECTRICAL CHARACTERISTICS

## PIN DESCRIPTIONS

### DIGITAL INPUTS AND OUTPUT

The various serial bit-stream formats for the MC145053 are illustrated in the timing diagrams of Figures 9 through 14. Table 1 assists in selection of the appropriate diagram. Note that the ADC accepts 16 clocks which makes it SPI (Serial Peripheral Interface) compatible.

**Table 1. Timing Diagram Selection**

No. of Clocks in Serial Transfer	Using CS	Serial Transfer Interval	Figure No.
10	Yes	Don't Care	9
10	No	Don't Care	10
11 to 16	Yes	Shorter than Conversion	11
16	No	Shorter than Conversion	12
11 to 16	Yes	Longer than Conversion	13
16	No	Longer than Conversion	14

### $\overline{CS}$

#### Active-Low Chip Select Input (Pin 10)

Chip select initializes the chip to perform conversions and provides 3-state control of the data output pin ( $D_{OUT}$ ). While inactive high,  $\overline{CS}$  forces  $D_{OUT}$  to the high-impedance state and disables the data input ( $D_{IN}$ ) and serial clock (SCLK) pins. A high-to-low transition on  $\overline{CS}$  resets the serial data port and synchronizes it to the MPU data stream.  $\overline{CS}$  can remain active during the conversion cycle and can stay in the active low state for multiple serial transfers or  $\overline{CS}$  can be inactive high after each transfer. If  $\overline{CS}$  is kept active low between transfers, the length of each transfer is limited to either 10 or 16 SCLK cycles. If  $\overline{CS}$  is in the inactive high state between transfers, each transfer can be anywhere from 10 to 16 SCLK cycles long. See the SCLK pin description for a more detailed discussion of these requirements.

Spurious chip selects caused by system noise are minimized by the internal circuitry. Any transitions on the  $\overline{CS}$  pin are recognized as valid only if the level is maintained for about 2  $\mu$ s after the transition.

#### NOTE

If  $\overline{CS}$  is inactive high after the 10th SCLK cycle and then goes active low before the A/D conversion is complete, the conversion is aborted and the chip enters the initial state, ready for another serial transfer/conversion sequence. At this point, the output data register contains the result from the conversion before the aborted conversion. Note that the last step of the A/D conversion sequence is to update the output data register with the result. Therefore, if  $\overline{CS}$  goes active low in an attempt to abort the conversion too close to the end of the conversion sequence, the result register may be corrupted and the chip could be thrown out of sync with the processor until  $\overline{CS}$  is toggled again (refer to the AC Electrical Characteristics in the spec tables).

### $D_{OUT}$

#### Serial Data Output of the A/D Conversion Result (Pin 11)

This output is in the high-impedance state when  $\overline{CS}$  is inactive high. When the chip recognizes a valid active low on  $\overline{CS}$ ,  $D_{OUT}$  is taken out of the high-impedance state and is driven with the MSB of the previous conversion result. (For the first transfer after power-up, data on  $D_{OUT}$  is undefined for the entire transfer.) The value on  $D_{OUT}$  changes to the second most significant result bit upon the first falling edge of SCLK. The remaining result bits are shifted out in order, with the LSB appearing on  $D_{OUT}$  upon the ninth falling edge of SCLK. Note that the order of the transfer is MSB to LSB. Upon the 10th falling edge of SCLK,  $D_{OUT}$  is immediately driven low (if allowed by  $\overline{CS}$ ) so that transfers of more than 10 SCLKs read zeroes as the unused LSBs.

When  $\overline{CS}$  is held active low between transfers,  $D_{OUT}$  is driven from a low level to the MSB of the conversion result for three cases: Case 1 — upon the 16th SCLK falling edge if the transfer is longer than the conversion time (Figure 14); Case 2 — upon completion of a conversion for a 16-bit transfer interval shorter than the conversion (Figure 12); Case 3 — upon completion of a conversion for a 10-bit transfer (Figure 10).

### $D_{IN}$

#### Serial Data Input (Pin 12)

The four-bit serial input stream begins with the MSB of the analog mux address (or the user test mode) that is to be converted next. The address is shifted in on the first four rising edges of SCLK. After the four mux address bits have been received, the data on  $D_{IN}$  is ignored for the remainder of the present serial transfer. See Table 2 in **Applications Information**.

### SCLK

#### Serial Data Clock (Pin 13)

This clock input drives the internal I/O state machine to perform three major functions: (1) drives the data shift registers to simultaneously shift in the next mux address from the  $D_{IN}$  pin and shift out the previous conversion result on the  $D_{OUT}$  pin, (2) begins sampling the analog voltage onto the RC DAC as soon as the new mux address is available, and (3) transfers control to the A/D conversion state machine after the last bit of the previous conversion result has been shifted out on the  $D_{OUT}$  pin.

The serial data shift registers are completely static, allowing SCLK rates down to the dc. There are some cases, however, that require a minimum SCLK frequency as discussed later in this section. At least ten SCLK cycles are required for each simultaneous data transfer. If the 16-bit format is used, SCLK can be one continuous 16-bit stream or two intermittent 8-bit streams. After the serial port has been initiated to perform a serial transfer\*, the new mux address is shifted in

\* The serial port can be initiated in three ways: (1) a recognized  $\overline{CS}$  falling edge, (2) the end of an A/D conversion if the port is performing either a 10-bit or a 16-bit "shorter-than-conversion" transfer with  $\overline{CS}$  active low between transfers, and (3) the 16th falling edge of SCLK if the port is performing 16-bit "longer-than-conversion" transfers with  $\overline{CS}$  active low between transfers.

on the first four rising edges of SCLK, and the previous 10-bit conversion result is shifted out on the first nine falling edges of SCLK. After the fourth rising edge of SCLK, the new mux address is available; therefore, on the next edge of SCLK (the fourth falling edge), the analog input voltage on the selected mux input begins charging the RC DAC and continues to do so until the tenth falling edge of SCLK. After this tenth SCLK edge, the analog input voltage is disabled from the RC DAC and the RC DAC begins the “hold” portion of the A/D conversion sequence. Also upon this tenth SCLK edge, control of the internal circuitry is transferred to the internal clock oscillator which drives the successive approximation logic to complete the conversion. If 16 SCLK cycles are used during each transfer, then there is a constraint on the minimum SCLK frequency. Specifically, there must be at least one rising edge on SCLK before the A/D conversion is complete. If the SCLK frequency is too low and a rising edge does not occur during the conversion, the chip is thrown out of sync with the processor and  $\overline{CS}$  needs to be toggled in order to restore proper operation. If 10 SCLKs are used per transfer, then there is no lower frequency limit on SCLK. Also note that if the ADC is operated such that  $\overline{CS}$  is inactive high between transfers, then the number of SCLK cycles per transfer can be anything between 10 and 16 cycles, but the “rising edge” constraint is still in effect if more than 10 SCLKs are used. (If  $\overline{CS}$  stays active low for multiple transfers, the number of SCLK cycles must be either 10 or 16.)

## EOC

### End-of-Conversion Output (Pin 1)

EOC goes low on the tenth falling edge of SCLK. A low-to-high transition on EOC occurs when the A/D conversion is complete and the data is ready for transfer.

## ANALOG INPUTS AND TEST MODES

### AN0 through AN4

#### Analog Multiplexer Inputs (Pins 2 – 6)

The input AN0 is addressed by loading \$0 into the mux address register. AN1 is addressed by \$1, AN2 by \$2, AN3 by \$3, and AN4 by \$4. Table 2 shows the input format for a 16-bit stream. The mux features a break-before-make switching structure to minimize noise injection into the analog inputs. The source resistance driving these inputs must be  $\leq 1\text{ k}\Omega$ .

During normal operation, leakage currents through the analog mux from unselected channels to a selected channel

and leakage currents through the ESD protection diodes on the selected channel occur. These leakage currents cause an offset voltage to appear across any series source resistance on the selected channel. Therefore, any source resistance greater than  $1\text{ k}\Omega$  (Motorola test condition) may induce errors in excess of guaranteed specifications.

There are three tests available that verify the functionality of all the control logic as well as the successive approximation comparator. These tests are performed by addressing \$B, \$C, or \$D and they convert a voltage of  $(V_{\text{ref}} + V_{\text{AG}})/2$ ,  $V_{\text{AG}}$ , or  $V_{\text{ref}}$ , respectively. The voltages are obtained internally by sampling  $V_{\text{ref}}$  or  $V_{\text{AG}}$  onto the appropriate elements of the RC DAC during the sample phase. Addressing \$B, \$C, or \$D produces an output of \$200 (half scale), \$000, or \$3FF (full scale), respectively, if the converter is functioning properly. However, deviation from these values occurs in the presence of sufficient system noise (external to the chip) on  $V_{\text{DD}}$ ,  $V_{\text{SS}}$ ,  $V_{\text{ref}}$ , or  $V_{\text{AG}}$ .

## POWER AND REFERENCE PINS

### $V_{\text{SS}}$ and $V_{\text{DD}}$

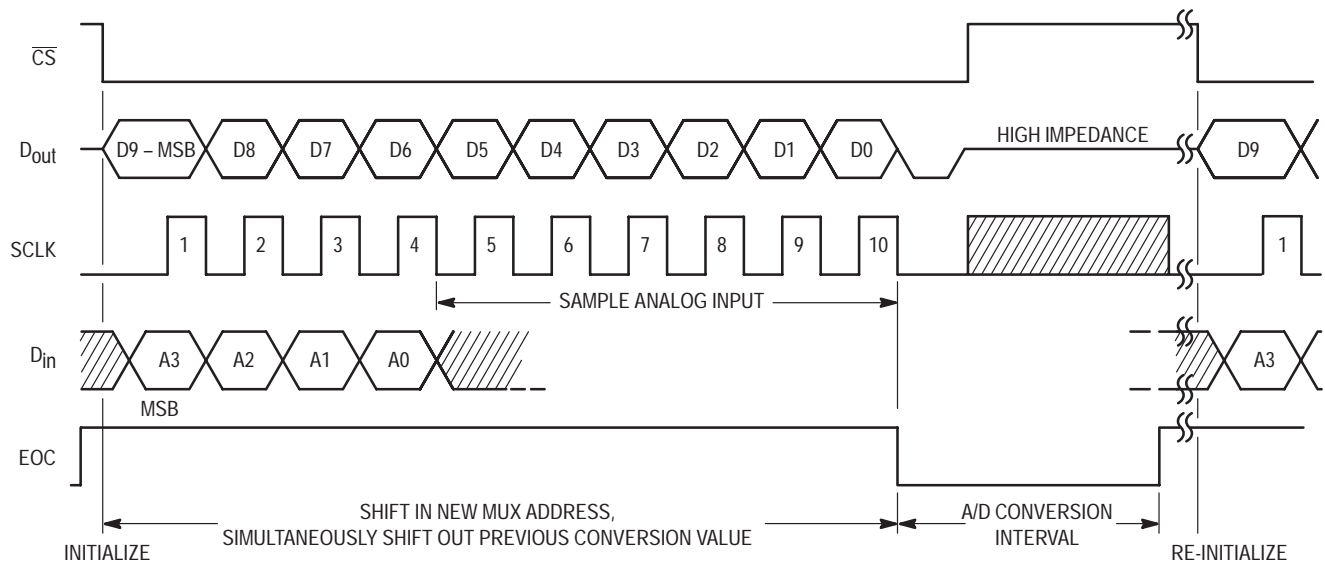

#### Device Supply Pins (Pins 7 and 14)

$V_{\text{SS}}$  is normally connected to digital ground;  $V_{\text{DD}}$  is connected to a positive digital supply voltage. Low frequency ( $V_{\text{DD}} - V_{\text{SS}}$ ) variations over the range of 4.5 to 5.5 volts do not affect the A/D accuracy. (See the Operations Ranges Table for restrictions on  $V_{\text{ref}}$  and  $V_{\text{AG}}$  relative to  $V_{\text{DD}}$  and  $V_{\text{SS}}$ .) Excessive inductance in the  $V_{\text{DD}}$  or  $V_{\text{SS}}$  lines, as on automatic test equipment, may cause A/D offsets  $> \pm 1\text{ LSB}$ . Use of a  $0.1\text{ }\mu\text{F}$  bypass capacitor across these pins is recommended.

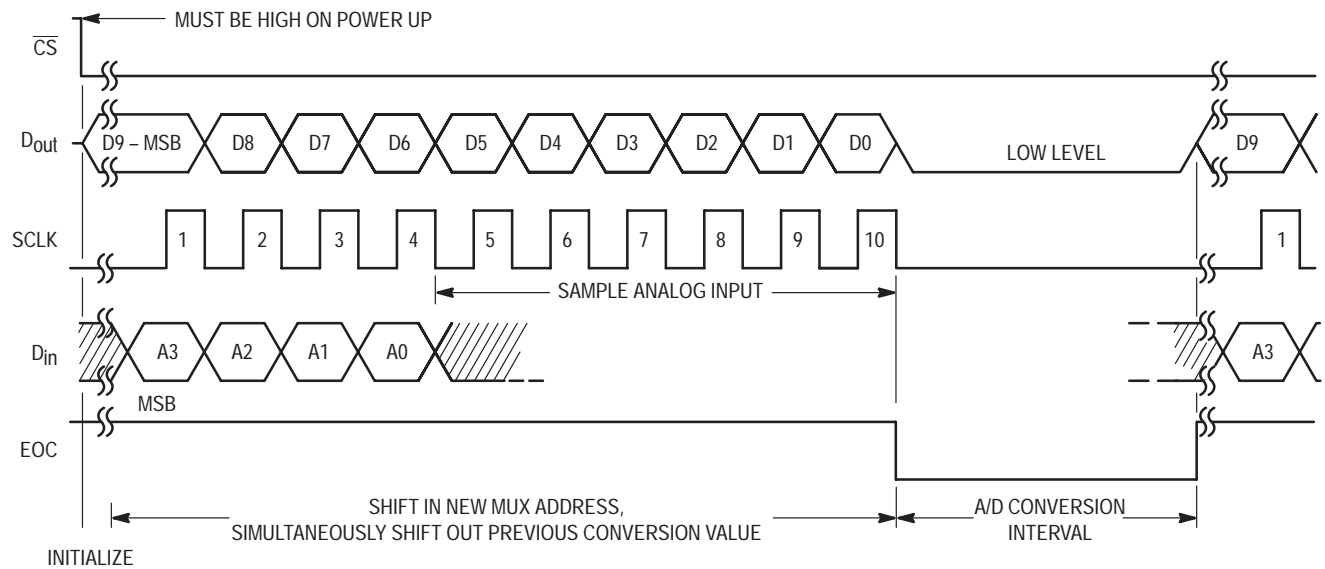

### $V_{\text{AG}}$ and $V_{\text{ref}}$

#### Analog Reference Voltage Pins (Pins 8 and 9)

Analog reference voltage pins which determine the lower and upper boundary of the A/D conversion. Analog input voltages  $\geq V_{\text{ref}}$  produce a full scale output and input voltages  $\leq V_{\text{AG}}$  produce an output of zero. CAUTION: The analog input voltage must be  $\geq V_{\text{SS}}$  and  $\leq V_{\text{DD}}$ . The A/D conversion result is ratiometric to  $V_{\text{ref}} - V_{\text{AG}}$ .  $V_{\text{ref}}$  and  $V_{\text{AG}}$  must be as noise-free as possible to avoid degradation of the A/D conversion. Ideally,  $V_{\text{ref}}$  and  $V_{\text{AG}}$  should be single-point connected to the voltage supply driving the system's transducers. Use of a  $0.22\text{ }\mu\text{F}$  bypass capacitor across these pins is strongly urged.

**Figure 9. Timing for 10-Clock Transfer Using  $\overline{CS}$**

**Figure 10. Timing for 10-Clock Transfer Not Using  $\overline{CS}$**

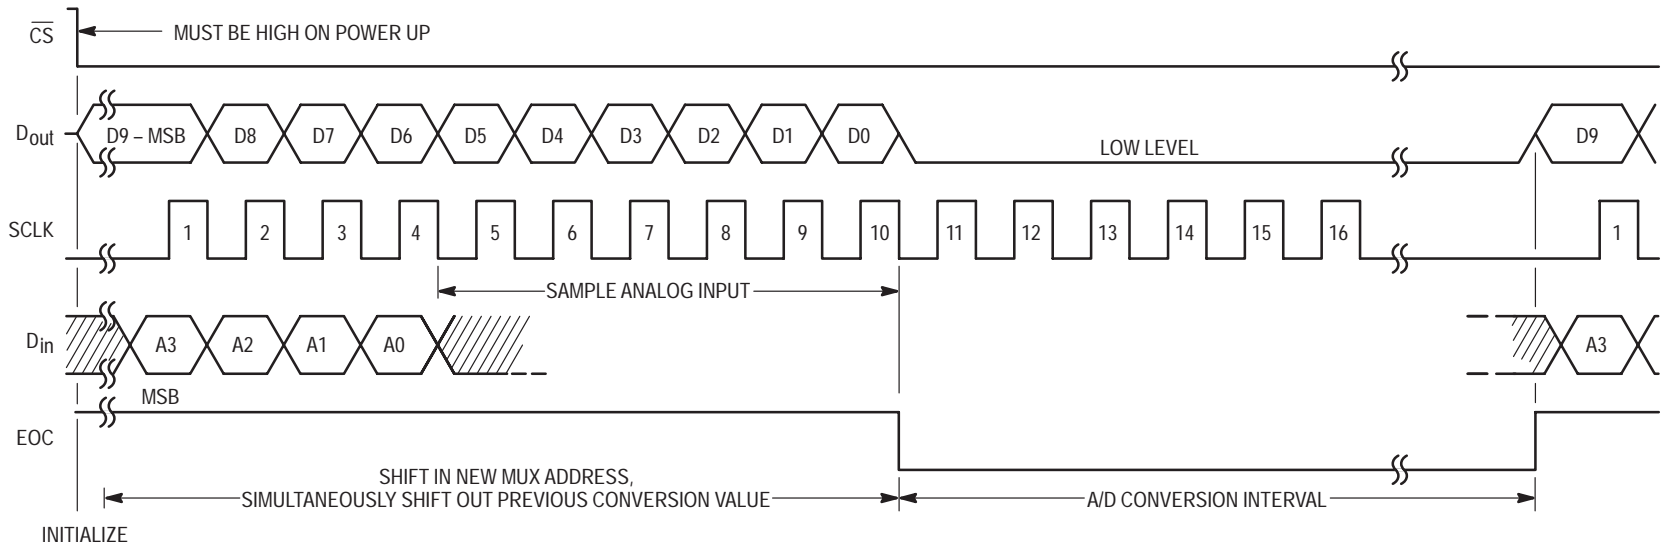

**NOTES:**

1. D9, D8, D7, D6, D5, ..., D0 = the result of the previous A/D conversion.
2. A3, A2, A1, A0 = the mux address for the next A/D conversion.

**Figure 11. Timing for 11- to 16-Clock Transfer Using  $\overline{CS}^*$  (Serial Transfer Interval Shorter than Conversion)**

**Figure 12. Timing for 16-Clock Transfer Not Using  $\overline{CS}^*$  (Serial Transfer Interval Shorter than Conversion)**

NOTES:

D9, D8, D7, . . . , D0 = the result of the previous A/D conversion.

A3, A2, A1, A0 = the mux address for the next A/D conversion.

\*This figure illustrates the behavior of the MC145051. The MC145050 behaves identically except there is no EOC signal and the conversion time is 44 ADCLK cycles (user-controlled time).

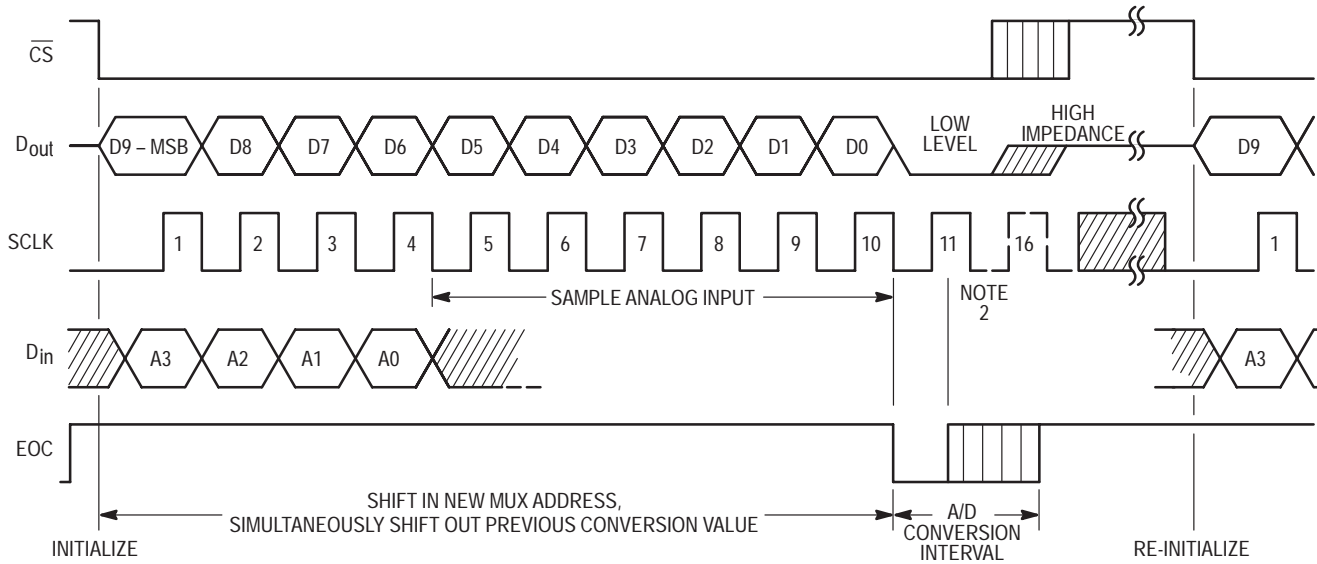

Figure 13. Timing for 11- to 16-Clock Transfer Using  $\overline{CS}^*$  (Serial Transfer Interval Longer Than Conversion)

Figure 14. Timing for 16-Clock Transfer Not Using  $\overline{CS}^*$  (Serial Transfer Interval Longer Than Conversion)

NOTES:

- D9, D8, D7, . . . , D0 = the result of the previous A/D conversion.
- A3, A2, A1, A0 = the mux address for the next A/D conversion.

\*NOTES:

- 1. This figure illustrates the behavior of the MC145051. The MC145050 behaves identically except there is no EOC signal and the conversion time is 44 ADCLK cycles (user-controlled time).
- 2. The 11th SCLK rising edge must occur before the conversion is complete. Otherwise the serial port is thrown out of sync with the microprocessor for the remainder of the transfer.

## APPLICATIONS INFORMATION

### DESCRIPTION

This example application of the MC145053 ADC interfaces four analog signals to a microprocessor.

Figure 15 illustrates how the MC145053 is used as a cost-effective means to simplify this type of circuit design. Utilizing one ADC, four analog inputs are interfaced to a CMOS or NMOS microprocessor with a serial peripheral interface (SPI) port. Processors with National Semiconductor's MICROWIRE serial port may also be used. Full duplex operation optimizes throughput for this system.

### DIGITAL DESIGN CONSIDERATIONS

Motorola's MC68HC05C4 CMOS MCU may be chosen to reduce power supply size and cost. The NMOS MCUs may be used if power consumption is not critical. A  $V_{DD}$  or  $V_{SS}$  0.1  $\mu\text{F}$  bypass capacitor should be closely mounted to the ADC.

The MC145053 has the end-of-conversion (EOC) signal at output pin 1 to define when data is ready.

### ANALOG DESIGN CONSIDERATIONS

Analog signal sources with output impedances of less than 1  $\text{k}\Omega$  may be directly interfaced to the ADC, eliminating the need for buffer amplifiers. Separate lines connect the  $V_{ref}$  and  $V_{AG}$  pins on the ADC with the controllers to provide isolation from system noise.

Although not indicated in Figure 15, the  $V_{ref}$  and sensor output lines may need to be shielded, depending on their length and electrical environment. This should be verified during prototyping with an oscilloscope. If shielding is required, a twisted pair or foil-shielded wire (not coax) is appropriate for this low frequency application. One wire of the pair or the shield must be  $V_{AG}$ .

A reference circuit voltage of 5 volts is used for the application shown in Figure 15. However, the reference circuitry may be simplified by tying  $V_{AG}$  to system ground and  $V_{ref}$  to the system's positive supply. (See Figure 16.)

A bypass capacitor of approximately 0.22  $\mu\text{F}$  across the  $V_{ref}$  and  $V_{AG}$  pins is recommended. These pins are adjacent on the ADC package which facilitates mounting the capacitor very close to the ADC.

### SOFTWARE CONSIDERATIONS

The software flow for acquisition is straightforward. The four analog inputs, AN0 through AN3, are scanned by reading the analog value of the previously addressed channel into the MCU and sending the address of the next channel to be read to the ADC, simultaneously.

The designer utilizing the MC145053 has the end-of-conversion signal (at pin 1) to define the conversion interval. EOC may be used to generate an interrupt, which is serviced by reading the serial data from the ADC. The software flow should then process and format the data.

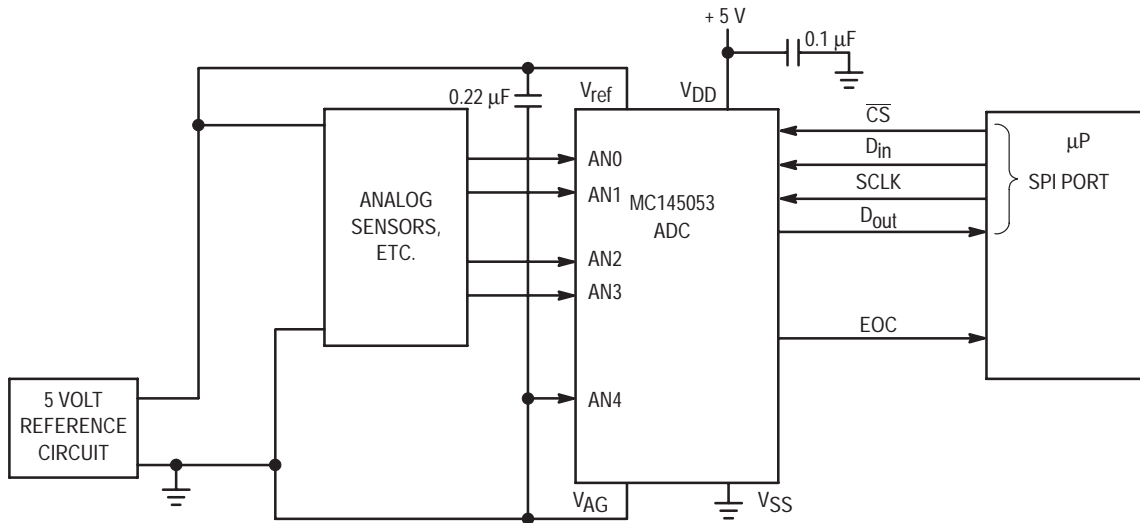

When this ADC is used with a 16-bit (2-byte) transfer, there are two types of offsets involved. In the first type of offset, the channel information sent to the ADCs is offset by 12 bits. That is, in the 16-bit stream, only the first 4 bits (4 MSBs) contain the channel information. The balance of the bits are don't cares. This results in 3 don't-care nibbles, as shown in Table 2. The second type of offset is in the conversion result returned from the ADC; this is offset by 6 bits. In the 16-bit stream, the first 10 bits (10 MSBs) contain the conversion result. The last 6 bits are zeroes. The hexadecimal result is shown in the first column of Table 3. The second column shows the result after the offset is removed by a microprocessor routine. If the 16-bit format is used, the ADC can transfer one continuous 16-bit stream or two intermittent 8-bit streams.

## The MRFIC Line Integrated GPS Downconverter

This integrated circuit is intended for GPS receiver applications. The dual conversion design is implemented in Motorola's low-cost high performance MOSAIC 3 silicon bipolar process and is packaged in a low-cost surface mount TQFP-48 package. In addition to the mixers, a VCO, a PLL and a loop filter are integrated on-chip. Output IF is nominally 9.5 MHz.

- 65 dB Minimum Conversion Gain
- 5 Volts Operation
- 50 mA Typical Current Consumption
- Low-Cost, Low Profile Plastic LQFP Package
- Order MRFIC1502R2 for Tape and Reel.  
R2 Suffix = 1,500 Units per 16 mm, 13 inch Reel.
- Device Marking = M1502

## APPLICATION INFORMATION

### Design Philosophy

The MRFIC1502 design is a standard dual downconversion configuration with an integrated fixed frequency phase-locked loop to generate the two local oscillators and the buffer to generate the sampling clock for a digital correlator and decimator. The active device for the L-band VCO is also integrated on the chip. This chip is designed in the third generation of Motorola's Oxide Self Aligned Integrated Circuits (MOSAIC 3) silicon bipolar process.

### Circuit Considerations

The RF input to the MRFIC1502 is internally matched to 50 ohms. Therefore, only AC coupling is required on the input. The output of the amplifier is fed directly into the first mixer. This mixer is an active Gilbert Cell configuration. The output of the mixer is brought off-chip for filtering of the unwanted mixer products. The amplifier and mixer have their own V<sub>CC</sub> supply (pin 42) in order to reduce the amount of coupling to the other circuits. There are two bypass capacitors on this pin, one for the high frequency components and one for the lower frequency components. These two capacitors should be placed physically as close to the bias pin as possible to reduce the inductance in the path. The capacitors should also be grounded as close to the ground of the IC as possible, preferably through a ground plane.

The output impedance of the first mixer is 50 ohms, while the input impedance to the first IF amplifier is 1 kΩ. There is a trap (zero) designed in at the second LO frequency to limit the amount of LO leakage into the high gain first IF amplifier.

The first IF amplifier is a variable gain amplifier with 25 dB of gain and 40 dB of gain control. The gain control pin can be grounded to provide the maximum gain out of the amplifier. If the baseband design utilizes a multi-bit A/D converter in the digital signal processing chip, this amplifier could be used to control the input to the A/D converter. The amplifier has an external bypassing capacitor. This capacitor should be on the order of 0.01 μF, and again should be located near the package pin.

The second mixer design is also a Gilbert Cell configuration. The interface between the mixer and the second IF amplifier is differential in order to increase noise immunity. This differential interface is also brought off-chip so that some additional filtering could be added in parallel between the output of the mixer and input to the amplifier.

This filtering is primarily to reduce the amount of LO leakage into the final IF amplifier and is achieved using a single 3.9 pF capacitor across the differential ports. The value of the capacitor determines the high frequency of the low pass structure.

The supply pin for the IF circuits is pin 33. This supply pin should be isolated from the other chip supplies in order to reduce the amount of coupling. The recommended capacitors are a 47 pF and a 0.01 μF, in parallel to bypass the supply to ground and should be placed physically as close to the pin as possible.

The output of the second IF amplifier is 50 ohms with a bandwidth of ±5.0 MHz. This signal must be filtered before being digitized in order to limit the noise entering the A/D converter.

### VCO Resonator Design

The design and layout of the circuits around the voltage controlled oscillator (VCO) are the most sensitive of the entire layout. The active device and biasing resistors are integrated on the MRFIC1502. The external circuits consist of the power supply decoupling, the capacitors for the integrated supply superfilter, the resonator and frequency adjusting elements, and the bypassing capacitor on the emitter of the active device.

The VCO supply is isolated from the rest of the PLL circuits in order to reduce the amount of noise that could cause frequency/phase noise in the VCO. The supply should be filtered using a 22 μH inductor in series and a 27 pF and 0.01 μF in parallel. The 27 pF capacitor should be series resonant at least as high as the VCO frequency to get the most L-band bypassing as possible. The on-chip supply filter requires two capacitors off-chip to filter the supply. The capacitors on the input (pin 8) and output (pin 10) of the filter are 1.0 μF, and the output also has a high frequency bypass capacitor in parallel. The input capacitor should not be smaller than a 1.0 μF to insure stability of the supply filter.

The VCO design is a standard negative resistance cell with a buffer amplifier. The resonating structure is connected to the base of the active device and consists of a coupling capacitor, a hyper-abrupt varactor diode, and a wire wound chip inductor. With the values shown on the application

circuit, the VCO is centered at 1527.7 MHz, and the gain of the VCO is approximately 20 MHz/Volt.

The above performance is heavily dependent on the capacitive structure that is used as the emitter bypass on pin 6. The total capacitance should be approximately 1.0 pF; that can be achieved using either a discrete element or a microstrip open circuited stub. The evaluation circuit shown uses a 0.4 pF capacitor.

#### **Phase-locked Loop Design**

The VCO signal at 1527.68 MHz is divided by 40 to get the second LO frequency of 38.19 MHz. In addition to providing the LO to the second mixer, the 38 MHz signal is output through a translator and is used as the sampling clock for the digital correlator and decimator circuits. There is an additional divide by two so the signal used by the phase detector is at 19.096 MHz. The reference input to the phase detector (pin 18) has an input sensitivity of 400 mVpp minimum and 2.5 Vpp maximum.

The loop filter design is the standard op-amp loop filter, resulting in a type 2 second order loop. The layout of the

discrete components around the loop filter and VCO is very critical to the performance of the phase-locked loop. Care should be taken in routing the VCO control voltage line from the output of the loop filter to the varactor diode.

The output of the divide by 40 is buffered by a clock translator that converts the low level sine wave into a TTL level square wave. The loading on the buffer is high so the peak currents can reach as high as 50 mA with the maximum load of 1.0 k $\Omega$  in parallel with 40 pF on the output. Therefore, the translator has a dedicated V<sub>CC</sub> supply, pin 28, which requires external bypassing and isolation. The recommended bypassing uses two capacitors in parallel, a 47 pF and a 0.01  $\mu$ F capacitor.

#### **Conclusion**

The MRFIC1502 offers a highly integrated downconverter solution for GPS receivers. For more detailed applications information on GPS system design refer to application note AN1610, "Using Motorola's MRFIC1502 in Global Positioning System Receivers."

# Advance Information

## Integrated GPS Downconverter

This integrated circuit is intended for GPS receiver applications. The dual conversion design is implemented in Motorola's low-cost, high-performance MOSAIC 5™ silicon bipolar process and is packaged in a low-cost surface mount LQFP-48 package. In addition to the mixers, a VCO, PLL, Crystal Oscillator, optional bandpass IF filter, A/D converter and a loop filter are integrated on-chip. Output IF is nominally 4.1 MHz.

- 105 dB Typical Conversion Gain
- 2.7 V Operation
- 27 mA Typical Current Consumption
- Low-Cost, Low-Profile Plastic LQFP Package

MOSAIC 5 is a trademark of Motorola, Inc.

# 900 MHz ISM Band Transceiver Demonstration and Evaluation System

## INTRODUCTION

The DataRadioEVS1 is comprised of two individual components, the YS1CTRL (i.e. controller) and RFMOD2 Transceiver with Baseband (i.e. target). This system allows an individual to quickly evaluate and prototype a 902–928MHz ISM band, low–power transceiver for either full–duplex voice or data applications and can be used with a Motorola MC74HC05 based M68MMEVS05 system to develop and debug assembly code for the final product.

The controller is a MC68HC705C8A MCU based design complete with numeric keypad and display. The controller is used to access, read and set the internal registers of the baseband IC located on the target, and enable or disable the receiver and transmitter ICs. Additionally, revisions 2.0 and greater of the MCU support a simple data transmission/reception scheme which can be used to investigate low data rate operation.

The target is a MC13145 RF Receiver, MC13146 RF Transmitter, and MC33411 Analog Baseband system. This system supports low–power, FM transmission and reception in the unlicensed (i.e. FCC Part 15) 900 MHz ISM band and contains complete audio processing sections for both transmit and receive paths.

Additional literature, including the MC33411A/D or MC33410A/D, MC13145/D and MC13146/D data sheets, and AN1687/D and AN1691/D application notes should be consulted in conjunction with this manual. Please refer to the schematics, parts lists, and assembly diagrams at the end of this manual for additional detailed information.

## GETTING STARTED: CONTROLLER

The controller requires a 5.0 V power supply to operate the LCD display and a 3.0 to 5.5 V supply to operate the MCU. Since the MCU is specified to operate at about 2.0 MHz at lower supplies and about 4.0 MHz at higher supplies, it is recommended that the controller be operated at 5.0 V only.

Power and ground to the LCD display are connected to J1/J2, respectively, and power/ground for the MCU is connected to JP1, pins 1 and 2, respectively. Under normal operating conditions, the target will supply the MCU power requirements through a ribbon cable connected to this header.

If the target is a MC33411 based system, jumper J3 should be removed. If the target is labeled “Baseset”, jumper J5 should be installed. If the target is labeled “Handset”, jumper J5 should be removed. Jumper J6 can be used to reset the MCU, but should be removed for normal operation.

The controller's MCU system clock can either be provided by the target or by an on–board crystal. In general, it is recommended that the on–board crystal be used for prototyping and debugging purposes. If the on–board crystal will be used, jumpers J7 and J9 should be installed and

jumper J8 removed. If the target will supply the MCU system clock, remove jumpers J7 and J9 and install jumper J8.

Trimpot R1 is used to adjust the LCD contrast for best readability. If the LCD appears blank, the trimpot should be adjusted counterclockwise. If the LCD appears too dark, adjust the trimpot in the clockwise direction.

The 10–pin, 1:1 ribbon cable supplied with the system should be connected from JP1 of the controller to JP1 of the target before power is applied to either board.

## GETTING STARTED: TARGET

The target requires a 2.7 to 5.5 V supply. Since this supply is usually used to power the controller MCU, it should be limited to 3.0 to 5.5 V, and it is recommended that 5.0 V be used. Power and ground are connected to J4 and J5, respectively.

As shipped, the RF signals to/from the target are presented at the SMA (J3) for ease of connection to standard lab equipment. If actual transmission/reception is desired, connect the antenna supplied to the ANT hole using the nut/bolt and insulated washers provided, and remove C5 and re–solder it in C4's position. This redirects the matched RF source from the SMA to the ANT connection.

The target is optimized for 9,600 NRZ (4,800 RZ) data applications with no voice. If data will be supplied by the controller or controller emulator, a jumper should be placed between MTX/TXD and another jumper placed between MRX/RXD. If the data source will be to/from external equipment, transmitted data/ground can be connected to TXD and the ground contact located next to him, and received data can be observed at RXD and the ground contact located next to him.

Most data applications will not require the audio processing sections of the baseband IC. If, however, it is desired to use these audio processing sections in the data path, resistor R35 should be removed and a 1.0  $\mu$ F capacitor should be installed in C121's position (for received data), C120 should be removed and re–installed in C119's location, R41 should be removed, and a low value ( $<51 \Omega$ ) resistor placed in R39's location (for transmit data).

Trimmer capacitor C83 is used to adjust the 10 MHz reference crystal to as close to 10 MHz as possible. Use extreme caution if adjusting this capacitor, as any capacitive load appearing on the Fref test point can affect the reference frequency. Trimpot R40 is used to set the desired transmit peak deviation to a nominal  $\pm 40$  kHz.

## CONTROLLER OPERATION

Once all connections have been made as outlined above, power can be applied to the system. If separate supplies are being used for the controller 5.0 V supply and target  $V_{CC}$ , turn the 5.0 V supply on first.

## DataRadio EVS1

The controller will respond with a short message (YS1CTLR MCU Rx.x), followed by either “Handset” or “Baseset”, depending upon jumper J5’s setting. Next, the baseband device selected will be displayed (i.e. J3). The first register option will then appear. (See Table 2, Register Commands Table).

Once this sequence is complete, the keypad is used to scroll up or down through the register commands until the desired command is reached. The “#” key will scroll down and the “\*” key will scroll up. The “0” key can be depressed to read the contents of the current register. Pressing the “\*” or “#” keys will return the menu back to the previous register command. Entering any digit will begin entry of a new value to download to the device. The controller uses/displays Base 10 values.

When a new value has been entered, the “\*” key can be depressed to abort the download, or the “#” key can be depressed to download the value to the baseband IC. If the value is within the baseband’s acceptable range, the message “Download done!” will be briefly displayed, and the menu will return to the original register selected. If the value is out of range, the message “Error!! Too big!” will be displayed, and the download will be aborted.

Using these features, all of the individual functions associated with the baseband can be observed and modified, if desired. The user should refer to the baseband register map found in the respective baseband data sheet for additional information about these functions.

The baseband transmit, receive, 2nd LO PLL and internal reference counters are initialized to channel 2 operation (see Table 1, Channel Frequencies Table) upon power-up.

### TARGET OPERATION

The RFMOD2 target is arbitrarily referred to as either a “Baseset” or “Handset” unit, and is optimized to receive and transmit on opposite ends of the 900 MHz ISM band. Baseset units can only communicate with handset units, and vice versa.

The target is designed specifically for medium data rate applications, and is useful as configured to observe data communications from about 1,200 Bits/S to about 9,600 Bits/S if Manchester encoding is used. Audio path components have been installed, and audio applications can be investigated but require several modifications to the transmitter (peak deviation), receiver (bandwidth and

demodulator/detector), and baseband (PLL filters). Of course, the controller will have to set and modify the baseband registers for proper and acceptable audio performance.

### DATA MODE

Controller command #47 may be used to transfer a data byte to another receiving controller. A seven-bit data byte is transmitted as a start bit, data byte (LSB to MSB), odd parity bit, and stop bits. Prior to the start of the transmission, a preamble of zeros is transmitted to allow the receiver and transmitter to stabilize.

Controller command #48 is used to place the receiving controller in the data capture mode. This should be executed prior to transmitting the data. The message “Waiting for data” will be displayed once this command has been entered.

Five types of errors can occur with the receiver:

3. The preamble is not properly detected and the receiver will not acknowledge the data transfer. The “\*” (i.e., escape) key can be depressed to abort the receive operation and the receiver will display “Rx Data Aborted!”.
4. The preamble has initialized the receiver but a pulse of too short a duration is detected. The receiver will display “Timing Err Short”.
5. The preamble has initialized the receiver but a pulse of too long a duration is detected. The receiver will display “Timing Err Long”.
6. An even parity byte is detected. The receiver will display “Parity Error!”.
7. A framing error is detected, usually caused by the absence of the stop bit. The receiver will display “Framing error!”.

### GENERAL INFORMATION

With a careful study of the RFMOD2 design, the user will see that the system is very flexible and able to operate under many different conditions. Ultimately, each user’s individual requirements will have to be factored into a final design, and should include considerations such as channel spacing, image rejection, bandwidth, frequency band, tuning range, etc. The system, by its nature, has not been optimized for any one application but rather to be more general purpose in nature and as a vehicle for fast evaluation of the RF chipset and easy of prototyping.

Table 1. Channel Frequencies Table

Ch #	Baseset Tx (MHz)	Baseset Rx (MHz)	Handset Tx (MHz)	Handset (MHz)Rx
0	903.0	924.9	924.9	903.0
1	903.5	925.4	925.4	903.5
2	904.0	925.9	925.9	904.0
3	904.5	926.4	926.4	904.5
4	905.0	926.9	926.9	905.0

# DataRadio EVS1

## SYSTEM CHARACTERISTICS

### Transmitter:

- Transmission Type: FM
- Data Modulation: FSK
- Normal Baseband Operating RF Frequency Range: 904 MHz
- Normal Handset Operating RF Frequency Range: 926 MHz
- Tuning Sensitivity: 13 MHz/V, 0.5 to 2.5 V range
- Modulation Sensitivity:  $\pm 50$  kHz @  $-10$  dBv
- RF Output Power:  $-3.0$  to  $-1.0$  dBm

### Receiver:

- Normal Baseband Operating RF Frequency Range: 926 MHz
- Normal Handset Operating RF Frequency Range: 904 MHz
- 12 dB SINAD Sensitivity:  $-110$  dBm

- 20 dB SINAD Sensitivity:  $-106$  dBm
- 1st LO Tuning Sensitivity: 15 MHz/V, 0.5 to 2.5 V range
- Normal Baseband 1st LO Frequency: 999.7 MHz
- Normal Handset 1st LO Frequency: 977.7 MHz
- 1st IF Frequency: 73.7 MHz
- 2nd LO Frequency: 63 MHz
- 2nd IF Frequency: 10.7 MHz
- 2nd IF Bandwidth: 150 kHz
- Recovered Audio:  $-10$  dBV for  $\pm 40$  kHz Deviation

### Baseband:

- 2nd LO Frequency: 63 MHz
- 2nd LO Output Voltage: 180 mVpp, 25  $\Omega$  Load
- 2nd LO Tuning Sensitivity: 1.1 MHz/V, 0.5 to 2.5 V range
- External Reference Frequency: 10 MHz, crystal controlled
- Internal Reference Frequency: 100 kHz

2500	2.7 to 5.5	9.5	Serial Interface	MC12210	D/751B, DT/948E
2800	4.5 to 5.5	3.5	Fixed Divider	MC12179	D/751

<sup>(46)</sup>To be introduced: a) 1Q00; b) 2Q00; c) 3Q00

## Dual PLL Synthesizers

Maximum Frequency (MHz)	Supply Voltage (V)	Nominal Supply Current (mA)	Phase Detector	Device	Suffix/Case
60 @ 3.0 V both loops	2.5 to 5.5	3 @ 3 V	Serial Interface, Standby	MC145162	P/648, D/751B
85 @ 3.0 V both loops	2.5 to 5.5	3 @ 3 V	Serial Interface, Standby	MC145162-1	D/751B
550, 60	1.8 to 3.6	3	10 MHz Serial Interface, Multiple Standby Modes, Dual 8-Bit DACs, Voltage Multiplier for Phase Detectors (See Note).	MC145181	FTA/873C
1100 both loops	2.7 to 5.5	12	Serial Interface, Standby, Evaluation Kit – MC145220EVK	MC145220	F/803C, DT/948D
1200, 550	1.8 to 3.6	4	10 MHz Serial Interface, Multiple Standby Modes, Dual 8-Bit DACs, Voltage Multiplier for Phase Detectors (See Note).	MC145225	FTA/873C
2200, 550	1.8 to 3.6	5	10 MHz Serial Interface, Multiple Standby Modes, Dual 8-Bit DACs, Voltage Multiplier for Phase Detectors (See Note).	MC145230	FTA/873C

**NOTE:** The MC145230EVK development system may be used with the MC145181, MC145225, or MC145230. The MC145230 is soldered to a tested board; MC145181, MC145225 and MC145230 device samples are included. The user must supply the VCOs for the MC145181.

# PLL Building Blocks

## Prescalers

Frequency (MHz)	Divide Ratios	Single or Dual Modulus	Supply Voltage (V)	Supply Current (mA)	Features	Device	Suffix/Case
1100	64/65, 128/129	Dual	2.7 to 5.5	2.0 max	Low Power	MC12052A	D/751
1100	64/65, 128/129	Dual	2.7 to 5.5	2.5 max	Low Power, Standby	MC12053A	D/751
1100	126/128, 254/256	Dual	2.7 to 5.5	2.0 max	Low Power	MC12058	D/751
1100	10,20,40,80	Single	4.5 to 5.5	5.0 max		MC12080	D/751
1100	2, 4, 8	Single	2.7 to 5.5	4.5 max	Standby	MC12093	D/751
2000	64/65, 128/129	Dual	2.7 to 5.5	2.6 max	Low Power	MC12054A	D/751
2500	2, 4	Single	2.7 to 5.5	14 max	Standby	MC12095	D/751
2800	64, 128, 256	Single	4.5 to 5.5	11.5 max		MC12079	D/751
2800	64, 128	Single	4.5 to 5.5	14.5 max		MC12089	D/751

## Voltage Control Oscillators

Frequency (MHz)	Supply Voltage (V)	Features	Device	Suffix/Case
1300	2.7 to 5.5	Two high drive open collector outputs (Q, QB), Adjustable output amplitude, Low drive output for prescaler	MC12149	D/751

## Phase–Frequency Detectors

Frequency (MHz)	Supply Voltage (V)	Features	Device	Suffix/Case
800 (Typ)	4.75 to 5.5	MECL10H compatible	MCH12140	D/751

## Dual Modulus Prescaler

The MC12015, MC12016 and MC12017 are dual modulus prescalers which will drive divide by 32 and 33, 40 and 41, and 64 and 65, respectively. An internal regulator is provided to allow these devices to be used over a wide range of power-supply voltages. The devices may be operated by applying a supply voltage of 5.0 Vdc  $\pm$ 10% at Pin 7, or by applying an unregulated voltage source from 5.5Vdc to 9.5 Vdc to Pin 8.

- 225 MHz Toggle Frequency
- Low-Power 7.5 mA Maximum at 6.8 V
- Control Input and Output Are Compatible With Standard CMOS
- Connecting Pins 2 and 3 Allows Driving One TTL Load
- Supply Voltage 4.5 V to 9.5 V

## MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Regulated Voltage, Pin 7	$V_{reg}$	8.0	Vdc
Power Supply Voltage, Pin 8	$V_{CC}$	10	Vdc
Operating Temperature Range	$T_A$	-40 to +85	°C
Storage Temperature Range	$T_{stg}$	-65 to +175	°C

**NOTE:** ESD data available upon request.

## ELECTRICAL CHARACTERISTICS ( $V_{CC} = 5.5$ to $9.5$ V; $V_{reg} = 4.5$ to $5.5$ V; $T_A = -40$ to $85$ °C, unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
Toggle Frequency (Sine Wave Input)	$f_{max}$	225	–	–	MHz
	$f_{min}$	–	–	35	
Supply Current	$I_{CC}$	–	6.0	7.8	mA
Control Input HIGH (+32, 40 or 64)	$V_{IH}$	2.0	–	–	V
Control Input LOW (+33, 41 or 65)	$V_{IL}$	–	–	0.8	V
Output Voltage HIGH ( $I_{source} = 50\mu A$ ) [Note 1]	$V_{OH}$	2.5	–	–	V
Output Voltage LOW ( $I_{sink} = 2mA$ ) [Note 1]	$V_{OL}$	–	–	0.5	V
Input Voltage Sensitivity	$V_{in}$	400	–	800	mVpp
		200	–	800	
PLL Response Time [Notes 2 and 3]	$t_{PLL}$	–	–	$t_{out}$ to 70	ns

**NOTES:** 1. Pin 2 connected to Pin 3.

2.  $t_{PLL}$  = the period of time the PLL has from the prescaler rising output transition (50%) to the modulus control input edge transition (50%) to ensure proper modulus selection.

3.  $t_{out}$  = period of output waveform.

# MC12019

## Dual Modulus Prescaler

The MC12019 is a divide by 20 and 21 dual modulus prescaler. It will divide by 20 when the modulus control input is HIGH and divide by 21 when the modulus control input is LOW.

- 225 MHz Toggle Frequency
- Low-Power 7.5 mA Maximum at 5.5 V
- Control Input is Compatible with Standard Motorola CMOS Synthesizers
- Emitter Follower Output

**NOT RECOMMENDED FOR NEW DESIGN  
DEVICE TO BE PHASED OUT.  
No replacement available.**

# 1.1 GHz Dual Modulus Prescaler

The MC12026 is a high frequency, low voltage dual modulus prescaler used in phase-locked loop (PLL) applications.

The MC12026A can be used with CMOS synthesizers requiring positive edges to trigger internal counters such as Motorola's MC145xxx series in a PLL to provide tuning signals up to 1.1 GHz in programmable frequency steps.

The MC12026B can be used with CMOS synthesizers requiring negative edges to trigger internal counters.

A Divide Ratio Control (SW) permits selection of an 8/9 or 16/17 divide ratio as desired.

The Modulus Control (MC) selects the proper divide number after SW has been biased to select the desired divide ratio.

**NOTE: The "B" Version Is Not Recommended for New Designs**

- 1.1 GHz Toggle Frequency
- Supply Voltage 4.5 to 5.5 V
- Low Power 4.0 mA Typical
- Operating Temperature Range of -40 to 85°C
- The MC12026 is Pin Compatible With the MC12022
- Short Setup Time ( $t_{set}$ ) 6ns Typical @ 1.1 GHz
- Modulus Control Input Level is Compatible With Standard CMOS and TTL

MC12026A IS NOT RECOMMENDED FOR NEW DESIGN  
DEVICE TO BE PHASED OUT.  
No replacement available.  
MC12026B is on Life Time Buy

# 1.1 GHz Super Low Power Dual Modulus Prescaler

The MC12052A is a super low power dual modulus prescaler used in phase-locked loop applications. Motorola's advanced Bipolar MOSAIC™ V technology is utilized to achieve low power dissipation of 2.7 mW at a minimum supply voltage of 2.7 V.

The MC12052A can be used with CMOS synthesizers requiring positive edges to trigger internal counters such as Motorola's MC145XXX series in a PLL to provide tuning signals up to 1.1 GHz in programmable frequency steps.

A Divide Ratio Control (SW) permits selection of a 64/65 or 128/129 divide ratio as desired.

The Modulus Control (MC) selects the proper divide number after SW has been biased to select the desired divide ratio.

- 1.1 GHz Toggle Frequency
- The MC12052 is Pin and Functionally Compatible with the MC12022
- Low Power 1.0 mA Typical
- 2.0 mA Maximum, -40 to 85°C, V<sub>CC</sub> = 2.7 to 5.5 Vdc
- Short Setup Time (t<sub>set</sub>) 16 ns Maximum @ 1.1 GHz
- Modulus Control Input Level is Compatible with Standard CMOS and TTL
- Maximum Input Voltage Should Be Limited to 6.5 Vdc

MOSAIC V is a trademark of Motorola

**MOTOROLA**

# 1.1 GHz Super Low Power Dual Modulus Prescaler With Stand-By Mode

The MC12053A is a super low power  $\div 64/65$ ,  $\div 128/129$  dual modulus prescaler. Motorola's advanced Bipolar MOSAIC™ V technology is utilized to achieve low power dissipation of 4.3 mW at a minimum supply voltage of 2.7 V.

The Divide Ratio Control input, SW, permits selection of divide ratio as desired. A HIGH on SW selects  $\div 64/65$ ; an OPEN on SW selects  $\div 128/129$ . The Modulus Control input, MC, selects the proper divide number after SW has been biased to select the desired divide ratio.

Stand-by mode is featured to reduce current drain to 50  $\mu$ A typical at 2.7 V when the stand-by pin, SB, is switched LOW, disabling the prescaler. On-chip output termination provides 500  $\mu$ A (typical) output current, which is sufficient to drive a CMOS synthesizer input high impedance load (8.0 pF typical).

- 1.1 GHz Toggle Frequency
- Supply Voltage of 2.7 to 5.5 V
- Low Power 1.5 mA Typical at  $V_{CC} = 2.7$  V
- Operating Temperature Range of  $-40$  to  $85^{\circ}\text{C}$
- On-Chip Output Termination
- The MC12053A Is Pin and Functionally Compatible With the MC12036
- Modulus Control Input Level Is Compatible With Standard CMOS and TTL

MOSAIC V is a trademark of Motorola

**MOTOROLA**

# 2.0 GHz Super Low Power Dual Modulus Prescaler

The MC12054A is a super low power dual modulus prescaler used in phase-locked loop applications. Motorola's advanced Bipolar MOSAIC™ V technology is utilized to achieve low power dissipation of 5.4 mW at a minimum supply voltage of 2.7 V.

The MC12054A can be used with CMOS synthesizers requiring positive edges to trigger internal counters such as Motorola's MC145XXX series in a PLL to provide tuning signals up to 2.0 GHz in programmable frequency steps.

A Divide Ratio Control (SW) permits selection of a 64/65 or 128/129 divide ratio as desired.

The Modulus Control (MC) selects the proper divide number after SW has been biased to select the desired divide ratio.

- 2.0 GHz Toggle Frequency
- The MC12054 is Pin and Functionally Compatible with the MC12031
- Low Power 2.0 mA Typical
- 2.6mA Maximum, -40 to 85°C, V<sub>CC</sub> = 2.7 to 5.5 Vdc
- Short Setup Time (t<sub>set</sub>) 10ns Maximum @ 2.0 GHz
- Modulus Control Input Level is Compatible with Standard CMOS and TTL
- Maximum Input Voltage Should Be Limited to 6.5 Vdc

MOSAIC V is a trademark of Motorola

## FUNCTIONAL TABLE

# 1.1 GHz Low Power Dual Modulus Prescaler

The MC12058 is a low power  $\div 126/128$ ,  $\div 254/256$  dual modulus prescaler. Motorola's advanced Bipolar MOSAIC™ V technology is utilized to achieve low power dissipation of 3.0 mW at a minimum supply voltage of 2.7 V. The MC12058 can be operated down to a minimum supply voltage of 2.7 V required for battery operated portable systems.

On-chip output termination provides 250  $\mu$ A (typical) output current to drive a 8.0 pF (typical) high impedance load. The Divide Ratio Control input, SW, permits selection of divide ratio as desired. A HIGH on SW selects  $\div 126/128$ ; an OPEN on SW selects  $\div 254/256$ . The Modulus Control input, MC, selects the proper divide number after SW has been biased to select the desired divide ratio.

- 1.1 GHz Toggle Frequency
- Supply Voltage 2.7 to 5.5 V
- Low Power 1.1 mA Typical at  $V_{CC} = 3.0$  V
- Operating Temperature Range of  $-40$  to  $85^{\circ}\text{C}$
- On-Chip Output Termination

## 2.8 GHz Prescaler

The MC12079 is a single modulus divide by 64, 128, 256 prescaler for low power frequency division of a 2.8 GHz (typical) high frequency input signal. Divide ratio control inputs SW1 and SW2 select the required divide ratio of  $\div 64$ ,  $\div 128$ , or  $\div 256$ .

An external load resistor is required to terminate the output. A 1.2 k $\Omega$  resistor is recommended to achieve a 1.6 V<sub>pp</sub> output swing, when dividing a 1.1 GHz input signal by the minimum divide ratio of 64, assuming a 12 pF load. Output current can be minimized dependent on conditions such as output frequency, capacitive load being driven, and output voltage swing required. Typical values for load resistors are included in the V<sub>out</sub> specification for various divide ratios at 2.8 GHz input frequency.

- 2.8 GHz Toggle Frequency
- Supply Voltage 4.5 to 5.5 V
- Low Power 9mA Typical at V<sub>CC</sub> = 5.0 V
- Operating Temperature Range of -40 to 85°C

## 2.8 GHz Prescaler

The MC12089 is a single modulus divide by 64 and 128 prescaler for low power frequency division of a 2.8 GHz high frequency input signal. The low power (10.2 mA typical at 5.0 V) and high operating frequency features make this prescaler ideal in satellite TV receiver applications.

Divide ratio control input SW selects the required divide ratio of ÷64 or ÷128.

On-chip output termination provides 2.5 mA of output current to drive a 12 pF (typical) high impedance load. The output voltage swing under typical supply voltage and temperature conditions is 1.2 V. If additional drive is required for the prescaler output, an external resistor can be added in parallel from the OUT pin to Gnd to increase the output power. Care must be taken not to exceed the maximum allowable current through the output.

- 2.8 GHz Toggle Frequency
- Supply Voltage 4.5 to 5.5 V
- Low Power Dissipation 51 mW Typical
- Operating Temperature Range of -40 to 85°C

**MOTOROLA**

# ÷2, ÷4, ÷8 1.1GHz Low Power Prescaler with Stand-By Mode

The MC12093 is a single modulus prescaler for low power frequency division of a 1.1 GHz high frequency input signal. Motorola's advanced MOSAIC™ V technology is utilized to achieve low power dissipation of 6.75 mW at a minimum supply voltage of 2.7 V.

On-chip output termination provides output current to drive a 2.0 pF (typical) high impedance load. If additional drive is required for the prescaler output, an external resistor can be added parallel from the OUT pin to GND to increase the output power. Care must be taken not to exceed the maximum allowable current through the output.

Divide ratio control inputs SW1 and SW2 select the required divide ratio of ÷2, ÷4, or ÷8.

Stand-By mode is featured to reduce current drain to 50 µA typical when the standby pin SB is switched LOW disabling the prescaler.

- 1.1 GHz Toggle Frequency
- Supply Voltage 2.7 V to 5.5 Vdc
- Low Power 3.0 mA Typical
- Operating Temperature -40 to 85°C
- Divide by 2, 4 or 8 Selected by SW1 and SW2 Pins
- On-Chip Termination

# 2.5 GHz Low Power Prescaler With Stand-By Mode

The MC12095 is a single modulus prescaler for low power frequency division of a 2.5 GHz high frequency input signal. Motorola's advanced MOSAIC™ V technology is utilized to achieve low power dissipation of 24 mW at a minimum supply voltage of 2.7 V.

On-chip output termination provides output current to drive a 2.0 pF (typical) high impedance load. If additional drive is required for the prescaler output, an external resistor can be added in parallel from the OUT pin to GND to increase the output power. Care must be taken not to exceed the maximum allowable current through the output.

Divide ratio control input (SW) selects the required divide ratio of ÷2 or ÷4. Stand-By mode is available to reduce current drain to 100µA typical when the standby pin SB is switched LOW disabling the prescaler.

- 2.5 GHz Toggle Frequency
- Supply Voltage 2.7 V to 5.5 Vdc
- Low Power 8.7 mA Typical
- Operating Temperature -40 to 85°C
- Divide by 2 or 4 Selected by the SW Pin

**NOTE:** For applications up to 1.1 GHz, please consult the MC12093 datasheet. MOSAIC V is a trademark of Motorola

The MC12147 is intended for applications requiring high frequency signal generation up to 1300 MHz. An external tank circuit is used to determine the desired frequency of operation. The VCO is realized using an emitter-coupled pair topology. The MC12147 can be used with an integrated PLL IC such as the MC12202 1.1 GHz Frequency Synthesizer to realize a complete PLL sub-system. The device is specified to operate over a voltage supply range of 2.7 to 5.5 V. It has a typical current consumption of 13 mA at 3.0 V which makes it attractive for battery operated handheld systems.

**NOT RECOMMENDED FOR NEW DESIGN  
DEVICE TO BE PHASED OUT.  
Consider MC12149 for New Designs.**

**NOTE: The MC12147 is NOT suitable as a crystal oscillator.**

- Operates Up to 1.3 GHz
- Space-Efficient 8-Pin SOIC or SSOP Package
- Low Power 13 mA Typical @ 3.0 V Operation
- Supply Voltage of 2.7 to 5.5 V
- Typical 900MHz Performance
  - Phase Noise -105 dBc/Hz @ 100 kHz Offset
  - Tuning Voltage Sensitivity of 20 MHz/V
- Output Amplitude Adjustment Capability
- Two High Drive Outputs With a Typical Range from -8.0 to -2.0 dBm

The device has two high frequency outputs which make it attractive for transceiver applications which require both a transmit and receive local oscillator (LO) signal. The outputs Q and QB are available for servicing the receiver IF and transmitter up-converter single-ended. In receiver applications, the outputs can be used together if it is necessary to generate a differential signal for the receiver IF. Because the Q and QB outputs are open collector, terminations to the V<sub>CC</sub> supply are required for proper operation. Since the outputs are complementary, BOTH outputs must be terminated even if only one is needed. The Q and QB outputs have a nominal drive level of -8dBm to conserve power. If addition signal amplitude is needed, a level adjustment pin (CNTL) is available, which when tied to ground, boosts the nominal output levels to -2.0 dBm.

External components required for the MC12147 are: (1) tank circuit (LC network); (2) Inductor/capacitor to provide the termination for the open collector outputs; and (3) adequate supply voltage bypassing. The tank circuit consists of a high-Q inductor and varactor components. The preferred tank configuration allows the user to tune the VCO across the full supply range. VCO performance such as center frequency, tuning voltage sensitivity, and noise characteristics are dependent on the particular components and configuration of the VCO tank circuit.

## OPERATIONAL CHARACTERISTICS

A simplified schematic of the MC12147 is found in Figure 1. The oscillator incorporates positive feedback by coupling the base of transistor Q2 to the collector of transistor Q1. In order to minimize interaction between the VCO outputs and the oscillator tank transistor pair, a buffer is incorporated into the circuit. This differential buffer is realized by the Q3 and Q4 transistor pair. The differential buffer drives the gate which contains the primary open collector outputs, Q and QB. The output is actually a current which has been set by an internal bias driver to a nominal current of 4mA. Additional circuitry is incorporated into the tail of the current source which allows the current source to be increased to approximately 10mA. This is accommodated by the addition of a resistor which is brought out to the CNTL pin. When this pin is tied to ground, the additional current is sourced through the current source thus increasing the output amplitude of the Q/QB output pair. If less than 10 mA of current is needed, a resistor can be added to ground which reduces the amount of current.

### APPLICATION INFORMATION

Figure 2 illustrates the external components necessary for the proper operation of the VCO buffer. The tank circuit configuration in this figure allows the VCO to be tuned across the full operating voltage of the power supply. This is very important in 3V applications where it is desirable to utilize as much of the operating supply range as possible so as to minimize the VCO sensitivity (MHz/V). In most situations, it is desirable to keep the sensitivity low so the circuit will be less susceptible to external noise influences. An additional benefit to this configuration is that additional regulation/ filtering can

be incorporated into the  $V_{CC}$  line without compromising the tuning range of the VCO. With the AC-coupled tank configuration, the  $V_{tune}$  voltage can be greater than the  $V_{CC}$  voltage supplied to the device.

There are four main areas that the user directly influences the performance of the VCO. These include Tank Design, Output Termination Selection, Power Supply Decoupling, and Circuit Board Layout/Grounding.

The design of the tank circuit is critical to the proper operation of the VCO. This tank circuit directly impacts the main VCO operating characteristics:

- 1) Frequency of Operation
- 2) Tuning Sensitivity
- 3) Voltage Supply Pushing
- 4) Phase Noise Performance

The tank circuit, in its simplest form, is realized as an LC circuit which determines the VCO operating frequency. This is described in Equation 1.

$$f_0 = \frac{1}{2\pi \sqrt{LC}} \quad \text{Equation 1}$$

In the practical case, the capacitor is replaced with a varactor diode whose capacitance changes with the voltage applied, thus changing the resonant frequency at which the VCO tank operates. The capacitive component in Equation 1 also needs to include the input capacitance of the device and other circuit and parasitic elements. Typically, the inductor is realized as a surface mount chip or a wound-coil. In addition, the lead inductance and board inductance and capacitance also have an impact on the final operating point.

Figure 1. Simplified Schematic

# MC12147

Figure 2. MC12147 Typical External Component Connections

1. This input can be left open, tied to ground, or tied with a resistor to ground, depending on the desired output amplitude needed at the Q and QB output pair.
2. Typical values for R1 range from 5.0 kΩ to 10 kΩ.

A simplified linear approximation of the device, package, and typical board parasitics has been developed to aid the designer in selecting the proper tank circuit values. All the parasitic contributions have been lumped into a parasitic capacitive component and a parasitic inductive component. While this is not entirely accurate, it gives the designer a solid starting point for selecting the tank components.

Below are the parameters used in the model.

- Cp Parasitic Capacitance
- Lp Parasitic Inductance
- LT Inductance of Coil
- C1 Coupling Capacitor Value
- Cb Capacitor for decoupling the Bias Pin
- CV Varactor Diode Capacitance (Variable)

The values for these components are substituted into the following equations:

$$C_i = \frac{C_1 \times CV}{C_1 + CV} + C_p \quad \text{Equation 2}$$

$$C = \frac{C_i \times C_b}{C_i + C_b} \quad \text{Equation 3}$$

$$L = L_p + LT \quad \text{Equation 4}$$

From Figure 2, it can be seen that the varactor capacitance (CV) is in series with the coupling capacitor (C1). This is calculated in Equation 2. For analysis purposes, the parasitic capacitances (CP) are treated as a lumped element and placed in parallel with the series combination of C1 and CV. This compound capacitance (Ci) is in series with the bias capacitor (Cb) which is calculated in Equation 3. The influences of the various capacitances; C1, CP, and Cb, impact the design by reducing the variable capacitance effects of the varactor which controls the tank resonant frequency and tuning range.

Now the results calculated from Equation 2, Equation 3 and Equation 4 can be substituted into Equation 1 to calculate the actual frequency of the tank.

To aid in analysis, it is recommended that the designer use a simple spreadsheet based on Equation 1 through Equation 4 to calculate the frequency of operation for various varactor/inductor selections before determining the initial starting condition for the tank.

The two main components at the heart of the tank are the inductor (LT) and the varactor diode (CV). The capacitance of a varactor diode junction changes with the amount of reverse bias voltage applied across the two terminals. This is the element which actually “tunes” the VCO. One characteristic of the varactor is the tuning ratio which is the ratio of the capacitance at specified minimum and maximum voltage points. For characterizing the MC12147, a Matsushita (Panasonic) varactor – MA393 was selected. This device has a typical capacitance of 11 pF at 1V and 3.7 pF at 4V and the C–V characteristic is fairly linear over that range. Similar performance was also achieved with Loral varactors. A multi-layer chip inductor was used to realize the LT component. These inductors had typical Q values in the 35–50 range for frequencies between 500 and 1000MHz.

**Note:** There are many suppliers of high performance varactors and inductors and Motorola can not recommend one vendor over another.

The Q (quality factor) of the components in the tank circuit has a direct impact on the resulting phase noise of the oscillator. In general, the higher the Q, the lower the phase noise of the resulting oscillator. In addition to the LT and CV components, only high quality surface-mount RF chip capacitors should be used in the tank circuit. These capacitors should have very low dielectric loss (high-Q). At a minimum, the capacitors selected should be operating 100 MHz below their series resonance point. As the desired frequency of operation increases, the values of the C1 and Cb capacitors will decrease since the series resonance point

## MC12147

is a function of the capacitance value. To simplify the selection of C1 and Cb, a table has been constructed based on the intended operating frequency to provide recommended starting points. These may need to be altered depending on the value of the varactor selected.

Frequency	C1	Cb
200 – 500 MHz	47 pF	47 pF
500 – 900 MHz	5.1 pF	15 pF
900 – 1200 MHz	2.7 pF	15 pF

The value of the Cb capacitor influences the VCO supply pushing. To minimize pushing, the Cb capacitor should be kept small. Since C1 is in series with the varactor, there is a strong relationship between these two components which influences the VCO sensitivity. Increasing the value of C1 tends to increase the sensitivity of the VCO.

The parasitic contributions Lp and Cp are related to the MC12147 as well as parasitics associated with the layout, tank components, and board material selected. The input capacitance of the device, bond pad, the wire bond, package/lead capacitance, wire bond inductance, lead inductance, printed circuit board layout, board dielectric, and proximity to the ground plane all have an impact on these parasitics. For example, if the ground plane is located directly below the tank components, a parasitic capacitor will be formed consisting of the solder pad, metal traces, board dielectric material, and the ground plane. The test fixture used for characterizing the device consisted of a two sided copper clad board with ground plane on the back. Nominal values were determined by selecting a varactor and characterizing the device with a number of different tank/frequency combinations and then performing a curve fit with the data to determine values for Lp and Cp. The nominal values for the parasitic effects are seen below:

Parasitic Capacitance	Cp	4.2 pF
Parasitic Inductance	Lp	2.2 nH

These values will vary based on the users unique circuit board configuration.

### Basic Guidelines:

1. Select a varactor with high Q and a reasonable capacitance versus voltage slope for the desired frequency range.
2. Select the value of Cb and C1 from the table above .
3. Calculate a value of inductance (L) which will result in achieving the desired center frequency. Note that L includes both LT and Lp.
4. Adjust the value of C1 to achieve the proper VCO sensitivity.
5. Re-adjust value of L to center VCO.
6. Prototype VCO design using selected components. It is important to use similar construction techniques and materials, board thickness, layout, ground plane spacing as intended for the final product.
7. Characterize tuning curve over the voltage operation conditions.
8. Adjust, as necessary, component values – L,C1, and Cb to compensate for parasitic board effects.
9. Evaluate over temperature and voltage limits.

10. Perform worst case analysis of tank component variation to insure proper VCO operation over full temperature and voltage range and make any adjustments as needed.

Outputs Q and QB are open collector outputs and need a inductor to VCC to provide the voltage bias to the output transistor. In most applications, dc-blocking capacitors are placed in series with the output to remove the dc component before interfacing to other circuitry. These outputs are complementary and should have identical inductor values for each output. This will minimize switching noise on the VCC supply caused by the outputs switching. It is important that both outputs be terminated, even if only one of the outputs is used in the application.

Referring to Figure 2, the recommended value for L2a and L2b should be 47 nH and the inductor components resonance should be at least 300 MHz greater than the maximum operating frequency. For operation above 1100 MHz, it may be necessary to reduce that inductor value to 33 nH. The recommended value for the coupling capacitors C6a, C6b, and C7 is 47 pF. Figure 2 also includes decoupling capacitors for the supply line as well as decoupling for the output inductors. Good RF decoupling practices should be used with a series of capacitors starting with high quality 100 pF chip capacitors close to the device. A typical layout is shown below in Figure 3.

The output amplitude of the Q and QB can be adjusted using the CNTL pin. Referring to Figure 1, if the CNTL pin is connected to ground, additional current will flow through the current source. When the pin is left open, the nominal current flowing through the outputs is 4 mA. When the pin is grounded, the current increases to a nominal value of 10 mA. So if a 50 ohm resistor was connected between the outputs and VCC, the output amplitude would change from 200 mV pp to 500 mV pp with an additional current drain for the device of 6 mA. To select a value between 4 and 10 mA, an external resistor can be added to ground. The equation below is used to calculate the current.

$$I_{out(nom)} = \frac{(200 + 136 + R_{ext}) \times 0.8V}{200 \times (136 + R_{ext})}$$

Figure 4 through Figure 13 illustrate typical performance achieved with the MC12147. The curves illustrate the tuning curve, supply pushing characteristics, output power, current drain, output spectrum, and phase noise performance. In most cases, data is present for both a 750 MHz and 1200 MHz tank design. The table below illustrates the component values used in the designs.

Component	750MHz Tank	1200MHz Tank	Units
R1	5000	5000	Ω
C1	5.1	2.7	pF
LT	4.7	1.8	nH
CV	3.7 @ 1.0 V 11 @ 4.0 V	3.7 @ 1.0 V 11 @ 4.0 V	pF
Cb	100*	15	pF
C6, C7	47	33	pF
L2	47	47	nH

\* The value of Cb should be reduced to minimize pushing.

# Low Power Voltage Controlled Oscillator

The MC12148 requires an external parallel tank circuit consisting of the inductor (L) and capacitor (C). A varactor diode may be incorporated into the tank circuit to provide a voltage variable input for the oscillator (VCO). This device may also be used in many other applications requiring a fixed frequency clock.

The MC12148 is ideal in applications requiring a local oscillator. Systems include electronic test equipment and digital high-speed telecommunications.

The MC12148 is based on the VCO circuit topology of the MC1648. The MC12148 has been realized utilizing Motorola's MOSAIC III advanced bipolar process technology which results in a design which can operate at a much higher frequency than the MC1648 while utilizing half the current. Please consult with the MC1648 data sheet for additional background information.

The ECL output circuitry of the MC12148 is not a traditional open emitter output structure and instead has an on-chip termination resistor with a nominal value of 500 ohms. This facilitates direct ac-coupling of the output signal into a transmission line. Because of this output configuration, an external pull-down resistor is not required to provide the output with a dc current path. This output is intended to drive one ECL load. If the user needs to fanout the signal, an ECL buffer such as the MC10EL16 Line Receiver/Driver should be used.

**NOTE: The MC12148 is NOT useable as a crystal oscillator.**

- Typical Operating Frequency Up to 1100 MHz
- Low-Power 20 mA at 5.0 Vdc Power Supply
- 8-Pin SOIC Package
- Phase Noise -90 dBc/Hz at 25 kHz Typical

NOT RECOMMENDED FOR NEW DESIGN  
DEVICE TO BE PHASED OUT.  
Consider MC12149 for New Designs.

# Low Power Voltage Controlled Oscillator Buffer

The MC12149 is intended for applications requiring high frequency signal generation up to 1300 MHz. An external tank circuit is used to determine the desired frequency of operation. The VCO is realized using an emitter-coupled pair topology. The MC12149 can be used with an integrated PLL IC such as the MC12202 1.1 GHz Frequency Synthesizer to realize a complete PLL sub-system. The device is specified to operate over a voltage supply range of 2.7 to 5.5 V. It has a typical current consumption of 15 mA at 3.0 V which makes it attractive for battery operated handheld systems.

**NOTE: The MC12149 is NOT suitable as a crystal oscillator.**

- Operates Up to 1.3 GHz
- Space-Efficient 8-Pin SOIC or SSOP Package
- Low Power 15 mA Typical @ 3.0 V Operation
- Supply Voltage of 2.7 to 5.5 V
- Typical 900 MHz Performance
  - Phase Noise  $-105$  dBc/Hz @ 100 kHz Offset
  - Tuning Voltage Sensitivity of 20 MHz/V
- Output Amplitude Adjustment Capability
- Two High Drive Outputs With a Typical Range from  $-8.0$  to  $-2.0$  dBm
- One Low-Drive Output for Interfacing to a Prescaler

The device has three high frequency outputs which make it attractive for transceiver applications which require both a transmit and receive local oscillator (LO) signal as well as a lower amplitude signal to drive the prescaler input of the frequency synthesizer. The outputs Q and QB are available for servicing the receiver IF and transmitter up-converter single-ended. In receiver applications, the outputs can be used together if it is necessary to generate a differential signal for the receiver IF. Because the Q and QB outputs are open collector, terminations to the  $V_{CC}$  supply are required for proper operation. Since the outputs are complementary, BOTH outputs must be terminated even if only one is needed. The Q and QB outputs have a nominal drive level of  $-8$  dBm to conserve power. If addition signal amplitude is needed, a level adjustment pin (CNTL) is available, which when tied to ground, boosts the nominal output levels to  $-2.0$  dBm. A low power VCO output (Q2) is also provided to drive the prescaler input of the PLL. The amplitude of this signal is nominally 500 mV which is suitable for most prescalers.

External components required for the MC12149 are: (1) tank circuit (LC network); (2) Inductor/capacitor to provide the termination for the open collector outputs; and (3) adequate supply voltage bypassing. The tank circuit consists of a high-Q inductor and varactor components. The preferred tank configuration allows the user to tune the VCO across the full supply range. VCO performance such as center frequency, tuning voltage sensitivity, and noise characteristics are dependent on the particular components and configuration of the VCO tank circuit.

# MC12149

## OPERATIONAL CHARACTERISTICS

A simplified schematic of the MC12149 is found in Figure 1. The oscillator incorporates positive feedback by coupling the base of transistor Q2 to the collector of transistor Q1. In order to minimize interaction between the VCO outputs and the oscillator tank transistor pair, a buffer is incorporated into the circuit. This differential buffer is realized by the Q3 and Q4 transistor pair. The differential buffer drives the gate which contains the primary open collector outputs, Q and QB. The output is actually a current which has been set by an internal bias driver to a nominal current of 4mA. Additional circuitry is incorporated into the tail of the current source which allows the current source to be increased to approximately 10 mA. This is accommodated by the addition of a resistor which is brought out to the CNTL pin. When this pin is tied to ground, the additional current is sourced through the current source thus increasing the output amplitude of the Q/QB output pair. If less than 10mA of current is needed, a resistor can be added to ground which reduces the amount of current.

The Q/QB outputs drive an additional differential buffer which generate the Q2 output signal. To minimize current, the circuit is realized as an emitter-follower buffer with an on chip pull down resistor. This output is intended to drive the prescaler input of the PLL synthesizer block.

### APPLICATION INFORMATION

Figure 2 illustrates the external components necessary for the proper operation of the VCO buffer. The tank circuit configuration in this figure allows the VCO to be tuned across the full operating voltage of the power supply. This is very important in 3.0 V applications where it is desirable to utilize as much of the operating supply range as possible so as to minimize the VCO sensitivity (MHz/V). In most situations, it is desirable to keep the sensitivity low so the circuit will be less

susceptible to external noise influences. An additional benefit to this configuration is that additional regulation/ filtering can be incorporated into the V<sub>CC</sub> line without compromising the tuning range of the VCO. With the ac-coupled tank configuration, the V<sub>tune</sub> voltage can be greater than the V<sub>CC</sub> voltage supplied to the device.

There are four main areas that the user directly influences the performance of the VCO. These include Tank Design, Output Termination Selection, Power Supply Decoupling, and Circuit Board Layout/Grounding.

The design of the tank circuit is critical to the proper operation of the VCO. This tank circuit directly impacts the main VCO operating characteristics:

- 1) Frequency of Operation
- 2) Tuning Sensitivity
- 3) Voltage Supply Pushing
- 4) Phase Noise Performance

The tank circuit, in its simplest form, is realized as an LC circuit which determines the VCO operating frequency. This is described in Equation 1.

$$f_o = \frac{1}{2\pi \sqrt{LC}} \quad \text{Equation 1}$$

In the practical case, the capacitor is replaced with a varactor diode whose capacitance changes with the voltage applied, thus changing the resonant frequency at which the VCO tank operates. The capacitive component in Equation 1 also needs to include the input capacitance of the device and other circuit and parasitic elements. Typically, the inductor is realized as a surface mount chip or a wound-coil. In addition, the lead inductance and board inductance and capacitance also have an impact on the final operating point.

Figure 1. Simplified Schematic

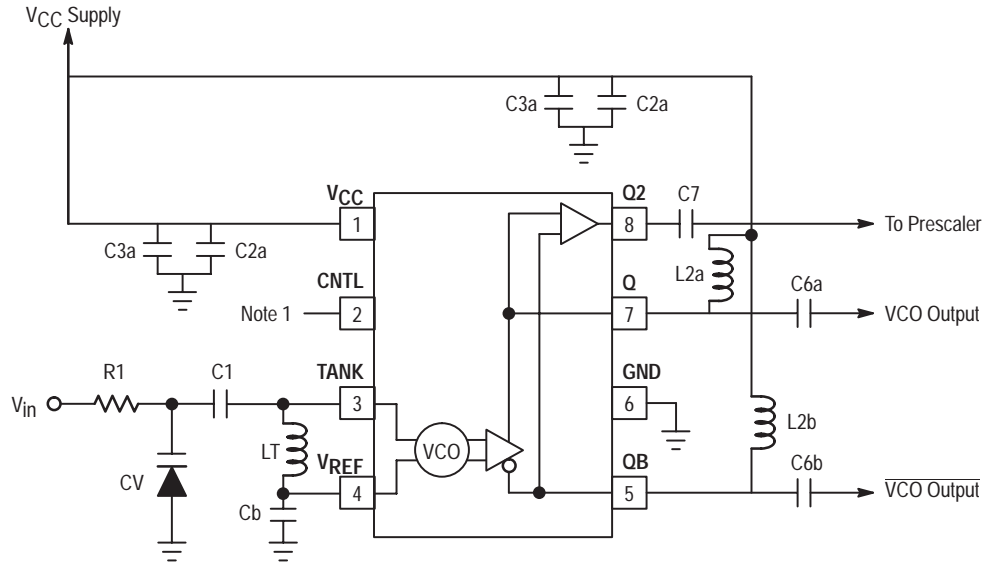

Figure 2. MC12149 Typical External Component Connections

1. This input can be left open, tied to ground, or tied with a resistor to ground, depending on the desired output amplitude needed at the Q and QB output pair.
2. Typical values for R1 range from 5.0 kΩ to 10 kΩ.

A simplified linear approximation of the device, package, and typical board parasitics has been developed to aid the designer in selecting the proper tank circuit values. All the parasitic contributions have been lumped into a parasitic capacitive component and a parasitic inductive component. While this is not entirely accurate, it gives the designer a solid starting point for selecting the tank components.

Below are the parameters used in the model.

- Cp Parasitic Capacitance
- Lp Parasitic Inductance
- LT Inductance of Coil
- C1 Coupling Capacitor Value
- Cb Capacitor for decoupling the Bias Pin
- CV Varactor Diode Capacitance (Variable)

The values for these components are substituted into the following equations:

$$C_i = \frac{C_1 \times C_V}{C_1 + C_V} + C_p \quad \text{Equation 2}$$

$$C = \frac{C_i \times C_b}{C_i + C_b} \quad \text{Equation 3}$$

$$L = L_p + L_T \quad \text{Equation 4}$$

From Figure 2, it can be seen that the varactor capacitance (CV) is in series with the coupling capacitor (C1). This is calculated in Equation 2. For analysis purposes, the parasitic capacitances (CP) are treated as a lumped element and placed in parallel with the series combination of C1 and CV. This compound capacitance (Ci) is in series with the bias capacitor (Cb) which is calculated in Equation 3. The influences of the various capacitances; C1, CP, and Cb, impact the design by reducing the variable capacitance effects of the varactor which controls the tank resonant frequency and tuning range.

Now the results calculated from Equation 2, Equation 3 and Equation 4 can be substituted into Equation 1 to calculate the actual frequency of the tank.

To aid in analysis, it is recommended that the designer use a simple spreadsheet based on Equation 1 through Equation 4 to calculate the frequency of operation for various varactor/inductor selections before determining the initial starting condition for the tank.

The two main components at the heart of the tank are the inductor (LT) and the varactor diode (CV). The capacitance of a varactor diode junction changes with the amount of reverse bias voltage applied across the two terminals. This is the element which actually “tunes” the VCO. One characteristic of the varactor is the tuning ratio which is the ratio of the capacitance at specified minimum and maximum voltage points. For characterizing the MC12149, a Matsushita (Panasonic) varactor – MA393 was selected. This device has a typical capacitance of 11 pF at 1.0 V and 3.7 pF at 4.0 V and the C–V characteristic is fairly linear over that range. Similar performance was also achieved with Loral varactors. A multi-layer chip inductor was used to realize the LT component. These inductors had typical Q values in the 35 to 50 range for frequencies between 500 and 1000 MHz.

**Note:** There are many suppliers of high performance varactors and inductors and Motorola can not recommend one vendor over another.

The Q (quality factor) of the components in the tank circuit has a direct impact on the resulting phase noise of the oscillator. In general, the higher the Q, the lower the phase noise of the resulting oscillator. In addition to the LT and CV components, only high quality surface-mount RF chip capacitors should be used in the tank circuit. These capacitors should have very low dielectric loss (high-Q). At a minimum, the capacitors selected should be operating 100 MHz below their series resonance point. As the desired frequency of operation increases, the values of the C1 and Cb capacitors will decrease since the series resonance point

## MC12149

is a function of the capacitance value. To simplify the selection of C1 and Cb, a table has been constructed based on the intended operating frequency to provide recommended starting points. These may need to be altered depending on the value of the varactor selected.

Frequency	C1	Cb
200 – 500 MHz	47 pF	47 pF
500 – 900 MHz	5.1 pF	15 pF
900 – 1200 MHz	2.7 pF	15 pF

The value of the Cb capacitor influences the VCO supply pushing. To minimize pushing, the Cb capacitor should be kept small. Since C1 is in series with the varactor, there is a strong relationship between these two components which influences the VCO sensitivity. Increasing the value of C1 tends to increase the sensitivity of the VCO.

The parasitic contributions Lp and Cp are related to the MC12149 as well as parasitics associated with the layout, tank components, and board material selected. The input capacitance of the device, bond pad, the wire bond, package/lead capacitance, wire bond inductance, lead inductance, printed circuit board layout, board dielectric, and proximity to the ground plane all have an impact on these parasitics. For example, if the ground plane is located directly below the tank components, a parasitic capacitor will be formed consisting of the solder pad, metal traces, board dielectric material, and the ground plane. The test fixture used for characterizing the device consisted of a two sided copper clad board with ground plane on the back. Nominal values were determined by selecting a varactor and characterizing the device with a number of different tank/frequency combinations and then performing a curve fit with the data to determine values for Lp and Cp. The nominal values for the parasitic effects are seen below:

Parasitic Capacitance	Cp	4.2 pF
Parasitic Inductance	Lp	2.2 nH

These values will vary based on the users unique circuit board configuration.

### Basic Guidelines:

1. Select a varactor with high Q and a reasonable capacitance versus voltage slope for the desired frequency range.
2. Select the value of Cb and C1 from the table above .
3. Calculate a value of inductance (L) which will result in achieving the desired center frequency. Note that L includes both LT and Lp.
4. Adjust the value of C1 to achieve the proper VCO sensitivity.
5. Re-adjust value of L to center VCO.
6. Prototype VCO design using selected components. It is important to use similar construction techniques and materials, board thickness, layout, ground plane spacing as intended for the final product.
7. Characterize tuning curve over the voltage operation conditions.
8. Adjust, as necessary, component values – L, C1, and Cb to compensate for parasitic board effects.
9. Evaluate over temperature and voltage limits.

10. Perform worst case analysis of tank component variation to insure proper VCO operation over full temperature and voltage range and make any adjustments as needed.

Outputs Q and QB are open collector outputs and need a inductor to VCC to provide the voltage bias to the output transistor. In most applications, DC-blocking capacitors are placed in series with the output to remove the DC component before interfacing to other circuitry. These outputs are complementary and should have identical inductor values for each output. This will minimize switching noise on the VCC supply caused by the outputs switching. It is important that both outputs be terminated, even if only one of the outputs is used in the application.

Referring to Figure 2, the recommended value for L2a and L2b should be 47 nH and the inductor components resonance should be at least 300 MHz greater than the maximum operating frequency. For operation above 1100 MHz, it may be necessary to reduce that inductor value to 33 nH. The recommended value for the coupling capacitors C6a, C6b, and C7 is 47 pF. Figure 2 also includes decoupling capacitors for the supply line as well as decoupling for the output inductors. Good RF decoupling practices should be used with a series of capacitors starting with high quality 100 pF chip capacitors close to the device. A typical layout is shown below in Figure 3.

The output amplitude of the Q and QB can be adjusted using the CNTL pin. Referring to Figure 1, if the CNTL pin is connected to ground, additional current will flow through the current source. When the pin is left open, the nominal current flowing through the outputs is 4 mA. When the pin is grounded, the current increases to a nominal value of 10 mA. So if a 50 ohm resistor was connected between the outputs and VCC, the output amplitude would change from 200 mV pp to 500 mV pp with an additional current drain for the device of 6 mA. To select a value between 4 and 10 mA, an external resistor can be added to ground. The equation below is used to calculate the current.

$$I_{out(nom)} = \frac{(200 + 136 + R_{ext}) \times 0.8V}{200 \times (136 + R_{ext})}$$

Figure 4 through Figure 13 illustrate typical performance achieved with the MC12149. The curves illustrate the tuning curve, supply pushing characteristics, output power, current drain, output spectrum, and phase noise performance. In most cases, data is present for both a 750 MHz and 1200 MHz tank design. The table below illustrates the component values used in the designs.

Component	750MHz Tank	1200MHz Tank	Units
R1	5000	5000	Ω
C1	5.1	2.7	pF
LT	4.7	1.8	nH
CV	3.7 @ 1.0 V 11 @ 4.0 V	3.7 @ 1.0 V 11 @ 4.0 V	pF
Cb	100*	15	pF
C6, C7	47	33	pF
L2	47	47	nH

**NOTE:** \* The value of Cb should be reduced to minimize pushing.

**MOTOROLA**

# 500-2800 MHz Single Channel Frequency Synthesizer

The MC12179 is a monolithic Bipolar synthesizer integrating the high frequency prescaler, phase/frequency detector, charge pump, and reference oscillator/buffer functions. When combined with an external loop filter and VCO, the MC12179 serves as a complete PLL subsystem. Motorola's advanced MOSAIC™ V technology is utilized for low power operation at a 5.0 V supply voltage. The device is designed for operation up to 2.8 GHz for high frequency applications such as CATV down converters and satellite receiver tuners.

- 2.8 GHz Maximum Operating Frequency
- Low Power Supply Current of 3.5 mA Typical, Including I<sub>CC</sub> and I<sub>p</sub> Currents
- Supply Voltage of 5.0 V Typical
- Integrated Divide by 256 Prescaler
- On-Chip Reference Oscillator/Buffer
  - 2.0 to 11 MHz Operation When Driven From Reference Source
  - 5.0 to 11 MHz Operation When Used With a Crystal
- Digital Phase/Frequency Detector with Linear Transfer Function
- Balanced Charge Pump Output
- Space Efficient 8-Lead SOIC
- Operating Temperature Range of -40 to 85°C

For additional information on calculating the loop filter components, an *InterActiveApNote*™ document containing software (based on a Microsoft Excel spreadsheet) and an Application Note is available. Please order DK306/D from the Motorola Literature Distribution Center.

## PIN FUNCTION DESCRIPTION

Pin	Symbol	I/O	Function
1	$OSC_{in}$	I	Oscillator Input — An external parallel-resonant, fundamental crystal is connected between $OSC_{in}$ and $OSC_{out}$ to form an internal reference oscillator (crystal mode). External capacitors $C_1$ and $C_2$ , as shown in Figure 1, are required to set the proper crystal load capacitance and oscillator frequency. For an external reference oscillator, an external signal is AC-coupled to the $OSC_{in}$ pin with a 1000 pF coupling capacitor, with no connection to $OSC_{out}$ . In either mode, a resistor with a nominal value of 50 k $\Omega$ MUST be placed across the $OSC_{in}$ and $OSC_{out}$ pins for proper operation.
2	$V_{CC}$	—	Positive Power Supply. Bypass capacitors should be placed as close as possible to the pin and be connected directly to the ground plane.
3	Gnd	—	Ground.
4	$F_{in}$	I	Prescaler Input — The VCO signal is AC coupled into the $F_{in}$ pin.
5	GndP	—	Ground — For charge pump circuitry.
6	$PD_{out}$	O	Single ended phase/frequency detector output (charge pump output). Three-state current sink/source output for use as a loop error signal when combined with an external low pass filter. The phase/frequency detector is characterized by a linear transfer function.
7	$V_P$	—	Positive power supply for charge pump. $V_P$ MUST be equal or greater than $V_{CC}$ . Bypass capacitors should be placed as close as possible to the pin and be connected directly to the ground plane.
8	$OSC_{out}$	O	Oscillator output, for use with an external crystal as shown in Figure 1.

# MC12179

Figure 1. MC12179 Expanded Block Diagram

## PHASE CHARACTERISTICS

The phase comparator in the MC12179 is a high speed digital phase/frequency detector circuit. The circuit determines the “lead” or “lag” phase relationship and time difference between the leading edges of the VCO ( $f_v$ ) signal and the reference ( $f_r$ ) input. The detector can cover a range of  $\pm 2\pi$  radian of  $f_v/f_r$  phase difference. The operation of the charge pump output is shown in Figure 2.

### $f_r$ lags $f_v$ in phase OR $f_v > f_r$ in frequency

When the phase of  $f_r$  lags that of  $f_v$  or the frequency of  $f_v$  is greater than  $f_r$ , the Do output will sink current. The pulse width will be determined by the time difference between the two rising edges.

### $f_r$ leads $f_v$ in phase OR $f_v < f_r$ in frequency

When the phase of  $f_r$  leads that of  $f_v$  or the frequency of  $f_v$  is less than  $f_r$ , the Do output will source current. The pulse width will be determined by the time difference between the two rising edges.

### $f_r = f_v$ in phase and frequency

When the phase and frequency of  $f_r$  and  $f_v$  are equal, the charge pump will be in a quiet state, except for current spikes when signals are in phase. This situation indicates that the loop is in lock and the phase comparator will maintain the loop in its locked state.

Figure 2. Phase/Frequency Detector and Charge Pump Waveforms

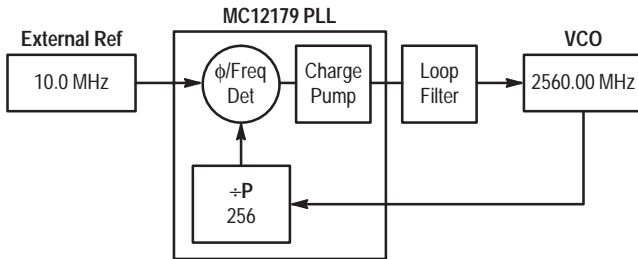

H = High voltage level; L = Low voltage level; Z = High impedance

NOTES: Phase difference detection range:  $\sim -2\pi$  to  $2\pi$

$$K_p\text{-Charge Pump Gain} \approx \frac{|I_{\text{source}}| + |I_{\text{sink}}|}{4\pi} = \frac{|2.2| + |-2.2|}{4\pi} = \frac{1.1 \text{ mA}}{\pi \text{ radian}}$$

The MC12179 is intended for applications where a fixed local oscillator is required to be synthesized. The prescaler on the MC12179 operates up to 2.8GHz which makes the part ideal for many satellite receiver applications as well as applications in the 2nd ISM (Industrial, Scientific, and Medical) band which covers the frequency range of 2400MHz to 2483MHz. The part is also intended for MMDS (Multi-channel Multi-point Distribution System) block downconverter applications. Below is a typical block diagram of the complete PLL.

Figure 3. Typical Block Diagram of Complete PLL

As can be seen from the block diagram, with the addition of a VCO, a loop filter, and either an external oscillator or crystal, a complete PLL sub-system can be realized. Since most of the PLL function is integrated into the MC12179, the user's primary focus is on the loop filter design and the crystal reference circuit. Figure 13 and Figure 14 illustrate typical VCO spectrum and phase noise characteristics. Figure 17 and Figure 18 illustrate the typical input impedance versus frequency for the prescaler input.

### Crystal Oscillator Design

The MC12179 is used as a multiply-by-256 PLL circuit which transfers the high stability characteristic of a low frequency reference source to the high frequency VCO in the PLL loop. To facilitate this, the device contains an input circuit which can be configured as a crystal oscillator or a buffer for accepting an external signal source.

In the external reference mode, the reference source is AC-coupled into the OSC<sub>IN</sub> input pin. The input level signal should be between 500–2200 mVpp. When configured with an external reference, the device can operate with input frequencies down to 2MHz, thus allowing the circuit to control the VCO down to 512 MHz. To optimize the phase noise of the PLL when used in this mode, the input signal amplitude should be closer to the upper specification limit. This maximizes the slew rate of the input signal as it switches against the internal voltage reference.

In the crystal mode, an external parallel-resonant fundamental mode crystal is connected between the OSC<sub>IN</sub> and OSC<sub>OUT</sub> pins. This crystal must be between 5.0 MHz and 11 MHz. External capacitors, C1 and C2 as shown in Figure 1, are required to set the proper crystal load capacitance and oscillator frequency. The values of the capacitors are dependent on the crystal chosen and the input capacitance of the device and any stray board capacitance.

In either mode, a 50kΩ resistor must be connected between the OSC<sub>IN</sub> and the OSC<sub>OUT</sub> pins for proper device operation. The value of this resistor is not critical so a 47kΩ or 51kΩ ±10% resistor is acceptable.

Since the MC12179 is realized with an all-bipolar ECL style design, the internal oscillator circuitry is different from more traditional CMOS oscillator designs which realize the crystal oscillator with a modified inverter topology. These CMOS designs typically excite the crystal with a rail-to-rail signal which may overdrive the crystal resulting in damage or unstable operation. The MC12179 design does not exhibit these phenomena because the swing out of the OSC<sub>OUT</sub> pin is less than 600mV. This has the added advantage of minimizing EMI and switching noise which can be generated by rail-to-rail CMOS outputs. The OSC<sub>OUT</sub> output should not be used to drive other circuitry.

The oscillator buffer in the MC12179 is a single stage, high speed, differential input/output amplifier; it may be considered to be a form of the Pierce oscillator. A simplified circuit diagram is seen in Figure 4.

Figure 4. Simplified Crystal Oscillator/Buffer Circuit

OSC<sub>IN</sub> drives the base of one input of an NPN transistor differential pair. The non-inverting input of the differential pair is internally biased. OSC<sub>OUT</sub> is the inverted input signal and is buffered by an emitter follower with a 70 μA pull-down current and has a voltage swing of about 600 mVpp. Open loop output impedance is about 425Ω. The opposite side of the differential amplifier output is used internally to drive another buffer stage which drives the phase/frequency detector. With the 50 kΩ feedback resistor in place, OSC<sub>IN</sub> and OSC<sub>OUT</sub> are biased to approximately 1.1V below V<sub>CC</sub>. The amplifier has a voltage gain of about 15 dB and a bandwidth in excess of 150 MHz. Adherence to good RF design and layout techniques, including power supply pin decoupling, is strongly recommended.

A typical crystal oscillator application is shown in Figure 1. The crystal and the feedback resistor are connected directly between OSC<sub>IN</sub> and OSC<sub>OUT</sub>, while the loading capacitors, C1 and C2, are connected between OSC<sub>IN</sub> and ground, and OSC<sub>OUT</sub> and ground respectively. It is important to understand that as far as the crystal is concerned, the two loading capacitors are in series (albeit through ground). So when the crystal specification defines a specific loading capacitance, this refers to the total external (to the crystal) capacitance seen across its two pins.

This capacitance consists of the capacitance contributed by the amplifier (IC and packaging), layout capacitance, and the series combination of the two loading capacitors. This is illustrated in the equation below:

Figure 6. Graphical Analysis of Optimum Bandwidth

Figure 7. Closed Loop Frequency Response for  $\zeta = 1$

To simplify analysis further a damping factor of 1 will be selected. The normalized closed loop response is illustrated in Figure 7 where the loop bandwidth is 2.5 times the loop natural frequency (the loop natural frequency is the frequency at which the loop would oscillate if it were unstable). Therefore the optimum loop bandwidth is

15kHz/2.5 or 6kHz (37.7krads) with a damping coefficient,  $\zeta \approx 1$ .  $T(s)$  is the transfer function of the loop filter.

Figure 8. Design Equations for the 2nd Order System

$$T(s) = \frac{R_0 C_0 s + 1}{\left(\frac{N C_0}{K_p K_V}\right) s^2 + R_0 C_0 s + 1} = \frac{\left(\frac{2\zeta}{\omega_0}\right) s + 1}{\left(\frac{1}{\omega_0^2}\right) s^2 + \left(\frac{2\zeta}{\omega_0}\right) s + 1}$$

$$\left(\frac{N C_0}{K_p K_V}\right) = \left(\frac{1}{\omega_0^2}\right) \rightarrow \omega_0 = \sqrt{\frac{K_p K_V}{N C_0}} \rightarrow C_0 \approx \left(\frac{K_p K_V}{N \omega_0^2}\right)$$

$$R_0 C_0 = \left(\frac{2\zeta}{\omega_0}\right) \rightarrow \zeta = \left(\frac{\omega_0 R_0 C_0}{2}\right) \rightarrow R_0 = \left(\frac{2\zeta}{\omega_0 C_0}\right)$$

In summary, follow the steps given below:

- Step 1: Plot the phase noise of crystal reference and the VCO on the same graph.
- Step 2: Increase the phase noise of the crystal reference by the noise contribution of the loop.
- Step 3: Convert the divide-by-N to dB ( $20\log 256 - 48$  dB) and increase the phase noise of the crystal reference by that amount.
- Step 4: The point at which the VCO phase noise crosses the amplified phase noise of the Crystal Reference is the point of the optimum loop bandwidth. This is approximately 15 kHz in Figure 6.
- Step 5: Correlate this loop bandwidth to the loop natural frequency and select components per Figure 8. In this case the 3.0 dB bandwidth for a damping coefficient of 1 is 2.5 times the loop's natural frequency. The relationship between the 3.0 dB loop bandwidth and the loop's "natural" frequency will vary for different values of  $\zeta$ . Making use of the equations defined above in a math tool or spreadsheet is useful. To aid in the use of such a tool the equations are summarized in Figures 9 through 11.

**Appendix: Derivation of Loop Filter Transfer Function**

The purpose of the loop filter is to convert the current from the phase detector to a tuning voltage for the VCO. The total transfer function is derived in two steps. Step 1 is to find the voltage generated by the impedance of the loop filter. Step 2 is to find the transfer function from the input of the loop filter to its output. The “voltage” times the “transfer function” is the

overall transfer function of the loop filter. To use these equations in determining the overall transfer function of a PLL multiply the filter’s impedance by the gain constant of the phase detector then multiply that by the filter’s transfer function (which is unity in the 2nd and 3rd order cases below).

# 125-1000 MHz Frequency Synthesizer

The MC12181 is a monolithic bipolar synthesizer integrating a high performance prescaler, programmable divider, phase/frequency detector, charge pump, and reference oscillator/buffer functions. The device is capable of synthesizing a signal which is 25 to 40 times the input reference signal. The device has a 4-bit parallel interface to set the proper total multiplication which can range from 25 to 40. When combined with an external passive loop filter and VCO, the MC12181 serves as a complete PLL subsystem.

- 2.7 to 5.5 V Operation
- Low power supply current of 4.25 mA typical
- On chip reference oscillator/buffer supporting wide frequency operating range from 5 to 25 MHz
- 4-bit parallel interface for programming divider (N = 25 .... 40)
- Wide 125 – 1000 MHz frequency of operation
- Digital phase/frequency detector with linear transfer function
- Balanced Charge Pump Output
- Space efficient 16 lead SOIC package
- Operating Temperature Range of –40 to 85°C
- > 1000 V ESD Protection (I/O to Ground, I/O to V<sub>CC</sub>)

The device is suitable for applications where a fixed local oscillator (LO) needs to be synthesized or where a limited number of LO frequencies need to be generated. The device also has auxiliary open emitter outputs (Pout and Rout) for observing the inputs to the phase detector for verification purposes. In normal use the pins should be left open. The Reset input is normally LOW. When this input is placed in the HIGH state the reference prescaler is reset and the charge pump output (Do) is placed in the OFF state.

The 4-bit programming interface maps into divider states ranging from 25 to 40. A is the LSB and D is the MSB. The data inputs (A,B,C, and D) are CMOS compatible and have pull-up resistors. The inputs can be tied directly to V<sub>cc</sub> or Ground for programming or can be interfaced to an external data latch/register. Table 1 below has a mapping of the programming states.

The MC12181 is intended for applications where a fixed LO, or a limited number of local oscillator frequencies is required to be synthesized. The device acts as a  $\times 25 - 40$  PLL. The 4-bit parallel interface allows 1 of 16 divide ratios to be selected. Internally there are fixed divide by 8 prescalers in the reference and programmable paths of the PLL. The MC12181 operates from 125 MHz to 1000 MHz which makes the part ideal for FCC Title 47; Part 15 applications in the 260 MHz to 470 MHz band and the 902 to 928 MHz Band. Figure 4 shows a typical block diagram of the application.

Figure 4. Typical Block Diagram of Complete PLL

As can be seen from the block diagram, with the addition of a VCO, a loop filter, and either an external oscillator or crystal, a complete PLL sub-system can be realized. Since most of the PLL functions are integrated into the 12181, the users focus is on the loop filter design and the crystal reference oscillator circuit.

### Crystal Oscillator Design

The PLL is used to transfer the high stability characteristic of a low frequency reference source to the high frequency VCO within the PLL loop. To facilitate this, the device contains an input circuit which can be configured as a crystal oscillator or a buffer for accepting an external signal source.

In the external reference mode, the reference source is ac-coupling into the OSC<sub>in</sub> input pin. The level of this signal should be between 500 – 2200 mV<sub>p-p</sub>. An external low noise reference should be used when it is desired to obtain the best close-in phase noise performance for the PLL. In addition the input reference amplitude should be close to the upper amplitude specification. This maximizes the slew rate of the input signal as it switches against the internal voltage reference.

In the crystal mode, an external parallel-resonant fundamental mode crystal should be connected between the OSC<sub>in</sub> and OSC<sub>out</sub> pins. This crystal must be between 5 and 25 MHz. External capacitors C1 and C2, as shown in Figure 2, are required to set the proper crystal load capacitance and oscillator frequency. The values of the capacitors are dependent on the crystal chosen and the input capacitance of the device as well as stray board capacitance.

Since the MC12181 is realized with an all-bipolar ECL style design, the internal oscillator circuitry is different from more traditional CMOS oscillator designs which realize the crystal oscillator with a modified inverter topology. These CMOS designs typically excite the crystal with a rail-to-rail signal which may overdrive the crystal resulting in damage or unstable operation. The MC12181 design does not exhibit this phenomena because the swing out of the OSC<sub>out</sub> pin is less than 600 mV<sub>p-p</sub>. This has the added advantage of

minimizing EMI and switching noise which can be generated by rail-to-rail CMOS outputs. The OSC<sub>out</sub> output should not be used to drive other circuitry.

The oscillator buffer in the MC12181 is a single stage, high speed, differential input/output amplifier; it may be considered to be a form of the Pierce oscillator. A simplified circuit diagram is seen in Figure 5.

Figure 5. Simplified Crystal Oscillator/Buffer Circuit

OSC<sub>in</sub> drives the base of one input of an NPN transistor differential pair. The non-inverting input of the differential pair is internally biased. OSC<sub>out</sub> is the inverted input signal and is buffered by an emitter follower with a 70  $\mu$ A pull-down current and has a voltage swing of about 600mV<sub>p-p</sub>. Open loop output impedance is approximately 425  $\Omega$ . The opposite side of the differential amplifier output is used internally to drive another buffer stage which drives the phase/frequency detector. With the 50 k $\Omega$  feedback resistor in place, OSC<sub>in</sub> and OSC<sub>out</sub> are biased to approximately 1.1 V below V<sub>CC</sub>. The amplifier has a voltage gain of about 15dB and a bandwidth in excess of 150 MHz. Adherence to good RF design and layout techniques, including power supply pin decoupling, is strongly recommended.

A typical crystal oscillator application is shown in Figure 2. The crystal and the feedback resistor are connected directly between OSC<sub>in</sub> and OSC<sub>out</sub>, while the loading capacitors, C1 and C2, are connected between OSC<sub>in</sub> and ground, and OSC<sub>out</sub> and ground respectively. It is important to understand that as far as the crystal is concerned, the two loading capacitors are in series (albeit through ground). So when the crystal specification defines a specific loading capacitance, this refers to the total external (to the crystal) capacitance seen across its two pins.

This capacitance consists of the capacitance contributed by the amplifier (IC and packaging), layout capacitance, and the series combination of the two loading capacitors. This is illustrated in the equation below:

$$C_l = C_{AMP} + C_{STRAY} + \frac{C_1 \times C_2}{C_1 + C_2}$$

Provided the crystal and associated components are located immediately next to the IC, thus minimizing the stray capacitance, the combined value of C<sub>AMP</sub> and C<sub>STRAY</sub> is approximately 5pF. Note that the location of the OSC<sub>in</sub> and OSC<sub>out</sub> pins at the end of the package, facilitates placing the crystal, resistor and the C1 and C2 capacitors very close to the device. Usually, one of the capacitors is in parallel with an adjustable capacitor used to trim the frequency of oscillation.

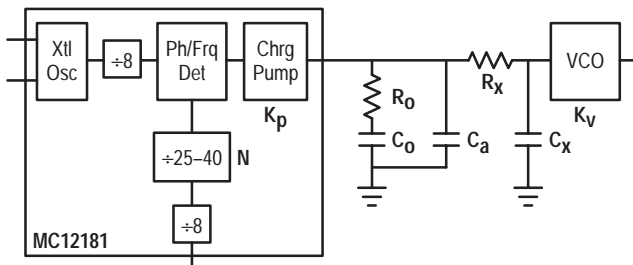

It is important that the total external (to the IC) capacitance seen by either  $OSC_{in}$  or  $OSC_{out}$ , be no greater than 30pF.

In operation, the crystal oscillator will start up with the application of power. If the crystal is in a can that is not grounded it is often possible to monitor the frequency of oscillation by connecting an oscilloscope probe to the can; this technique minimizes any disturbance to the circuit. If this is not possible, a high impedance, low capacitance, FET probe can be connected to either  $OSC_{in}$  or  $OSC_{out}$ . Signals typically seen at those points will be very nearly sinusoidal with amplitudes of roughly 300–600mVp-p. Some distortion is inevitable and has little bearing on the accuracy of the signal going to the phase detector.

**Loop Filter Design**

Because the device is designed for a non-frequency agile synthesizer (i.e., how fast it tunes is not critical) the loop filter design is very straight forward. The current output of the charge pump allows the loop filter to be realized without the need of any active components. The preferred topology for the filter is illustrated in Figure 6.

**Figure 6. Loop Filter**

The  $R_0/C_0$  components realize the primary loop filter.  $C_a$  is added to the loop filter to provide for reference sideband suppression. If additional suppression is needed, the  $R_x/C_x$  realizes an additional filter. In most applications, this will not be necessary. If all components are used, this results in a 4th order PLL, which makes analysis difficult. To simplify this, the loop design will be treated as a 2nd order loop ( $R_0/C_0$ ) and additional guidelines are provided to minimize the influence of the other components. If more rigorous analysis is needed, mathematical/system simulation tools should be used.

Component	Guideline
$C_a$	$<0.1 \times C_0$
$R_x$	$>10 \times R_0$
$C_x$	$<0.1 \times C_0$

The focus of the design effort is to determine what the loop's natural frequency,  $\omega_0$ , should be. This is determined by  $R_0$ ,  $C_0$ ,  $K_p$ ,  $K_v$ , and  $N_t$ . Because  $K_p$ ,  $K_v$ , and  $N_t$  are given, it is only necessary to calculate values for  $R_0$  and  $C_0$ . There are 3 considerations in selecting the loop bandwidth:

- 4) Maximum loop bandwidth for minimum tuning speed

- 5) Optimum loop bandwidth for best phase noise performance
- 6) Minimum loop bandwidth for greatest reference sideband suppression

Usually a compromise is struck between these 3 cases, however, for a fixed frequency application, minimizing the tuning speed is not a critical parameter.

To specify the loop bandwidth for optimal phase noise performance, an understanding of the sources of phase noise in the system and the effect of the loop filter on them is required. There are 3 major sources of phase noise in the phase-locked loop – the crystal reference, the VCO, and the loop contribution. The loop filter acts as a low-pass filter to the crystal reference and the loop contribution. The loop filter acts as a high-pass filter to the VCO with an in-band gain equal to unity. The loop contribution includes the PLL IC, as well as noise in the system; supply noise, switching noise, etc. For this example, a loop contribution of 15dB has been selected, which corresponds to data in Figure 17.

The crystal reference and the VCO are characterized as high-order 1/f noise sources. Graphical analysis is used to determine the optimum loop bandwidth. It is necessary to have noise plots from the manufacturers of both devices. This method provides a straightforward approximation suitable for quickly estimating the optimal bandwidth. The loop contribution is characterized as white-noise or low-order 1/f noise given in the form of a noise factor which combines all the noise effects into a single value. The phase noise of the Crystal Reference is increased by the noise factor of the PLL IC and related circuitry. It is further increased by the total divide-by-N ratio of the loop. This is illustrated in Figure 7.

The point at which the VCO phase noise crosses the amplified phase noise of the Crystal Reference is the point of the optimum loop bandwidth. In the example of Figure 7, the optimum bandwidth is approximately 15 KHz.

**Figure 7. Graphical Analysis of Optimum Bandwidth**

Figure 8. Closed Loop Frequency Response for  $\zeta = 1$

To simplify analysis further a damping factor of 1 will be selected. The normalized closed loop response is illustrated in Figure 8 where the loop bandwidth is 2.5 times the loop natural frequency (the loop natural frequency is the frequency at which the loop would oscillate if it were unstable). Therefore the optimum loop bandwidth is 15 kHz/2.5 or 6.0 kHz (37.7 krads) with a damping coefficient,  $\zeta \approx 1$ . T(s) is the transfer function of the loop filter.

$$T(s) = \frac{R_0 C_0 s + 1}{\left(\frac{N C_0}{K_p K_V}\right) s^2 + R_0 C_0 s + 1} = \frac{\left(\frac{2\zeta}{\omega_0}\right) s + 1}{\left(\frac{1}{\omega_0^2}\right) s^2 + \left(\frac{2\zeta}{\omega_0}\right) s + 1}$$

$$\left(\frac{N C_0}{K_p K_V}\right) = \left(\frac{1}{\omega_0^2}\right) \rightarrow \omega_0 = \sqrt{\frac{K_p K_V}{N C_0}} \rightarrow C_0 = \left(\frac{K_p K_V}{N \omega_0^2}\right)$$

$$R_0 C_0 = \left(\frac{2\zeta}{\omega_0}\right) \rightarrow \zeta = \left(\frac{\omega_0 R_0 C_0}{2}\right) \rightarrow R_0 = \left(\frac{2\zeta}{\omega_0 C_0}\right)$$

where  $N_t$  = Total PLL Divide Ratio —  $8 \times N$  where ( $N = 25 \dots 40$ )  
 $K_V$  = VCO Gain — Hz/V  
 $K_p$  = Phase Detector/Charge Pump Gain — A  
 = ( $|I_{OH}| + |I_{OL}|$ ) / 2

Technically,  $K_V$  and  $K_p$  should be expressed in Radian units [ $K_V$  (RAD/V),  $K_p$  (A/RAD)]. Since the component design equation contains the  $K_V \times K_p$  term, the  $2\pi$  cancels and the values can be expressed as above.

Figure 9. Design Equations for the 2nd Order System

In summary, follow the steps given below:

- Step 1: Plot the phase noise of crystal reference and the VCO on the same graph.
- Step 2: Increase the phase noise of the crystal reference by the noise contribution of the loop.
- Step 3: Convert the divide-by-N to dB ( $20 \log 8 \times N$ ) and increase the phase noise of the crystal reference by that amount.
- Step 4: The point at which the VCO phase noise crosses the amplified phase noise of the Crystal Reference is the point of the optimum loop bandwidth. This is approximately 15 kHz in Figure 7.
- Step 5: Correlate this loop bandwidth to the loop natural frequency per Figure 8. In this case the 3.0 dB bandwidth for a damping coefficient of 1 is 2.5 times the loop's natural frequency. The relationship between the 3.0 dB loop bandwidth and the loop's "natural" frequency will vary for different values of  $\zeta$ . Making use of the equations defined in Figure 9, a math tool or spread sheet is useful to select the values for  $R_0$  and  $C_0$ .

**Appendix: Derivation of Loop Filter Transfer Function**

The purpose of the loop filter is to convert the current from the phase detector to a tuning voltage for the VCO. The total transfer function is derived in two steps. Step 1 is to find the voltage generated by the impedance of the loop filter. Step 2 is to find the transfer function from the input of the loop filter to its output. The "voltage" times the "transfer function" is the overall transfer function of the loop filter. To use these equations in determining the overall transfer function of a PLL multiply the filter's impedance by the gain constant of the phase detector then multiply that by the filter's transfer function (Figure 10 contains the transfer function equations for 2nd, 3rd and 4th order PLL filters.)

# Serial Input PLL Frequency Synthesizer

The MC12210 is a 2.5 GHz Bipolar monolithic serial input phase locked loop (PLL) synthesizer with pulse–swallow function. It is designed to provide the high frequency local oscillator signal of an RF transceiver in handheld communication applications.

Motorola’s advanced Bipolar MOSAIC™ V technology is utilized for low power operation at a minimum supply voltage of 2.7 V. The device is designed for operation over 2.7 to 5.5 V supply range for input frequencies up to 2.5 GHz with a typical current drain of 9.5 mA. The low power consumption makes the MC12210 ideal for handheld battery operated applications such as cellular or cordless telephones, wireless LAN or personal communication services. A dual modulus prescaler is integrated to provide either a 32/33 or 64/65 divide ratio.

For additional applications information, two *InterActiveApNote*™ documents containing software (based on a Microsoft Excel spreadsheet) and an Application Note are available. Please order DK305/D and DK306/D from the Motorola Literature Distribution Center.

- Low Power Supply Current of 8.8 mA Typical for I<sub>CC</sub> and 0.7 mA Typical for I<sub>p</sub>
- Supply Voltage of 2.7 to 5.5 V
- Dual Modulus Prescaler With Selectable Divide Ratios of 32/33 or 64/65
- On–Chip Reference Oscillator/Buffer
- Programmable Reference Divider Consisting of a Binary 14–Bit Programmable Reference Counter
- Programmable Divider Consisting of a Binary 7–Bit Swallow Counter and an 11–Bit Programmable Counter
- Phase/Frequency Detector With Phase Conversion Function
- Balanced Charge Pump Outputs
- Dual Internal Charge Pumps for Bypassing the First Stage of the Loop Filter to Decrease Lock Time
- Outputs for External Charge Pump
- Operating Temperature Range of –40 to 85°C
- Space Efficient Plastic Surface Mount SOIC or TSSOP Packages

MOSAIC V, Mfax and *InterActiveApNote* are trademarks of Motorola, Inc.

## MAXIMUM RATINGS (Note 1)

Pin	I/O	Function	16-Lead Pkg Pin No.	20-Lead Pkg Pin No.
OSCin	I	Oscillator input. A crystal may be connected between OSCin and OSCout. It is highly recommended that an external source be ac coupled into this pin (see text).	1	1
OSCout	O	Oscillator output. Pin should be left open if external source is used	2	3
Vp	—	Power supply for charge pumps (Vp should be greater than or equal to VCC) Vp provides power to the Do, BISW and phi P outputs	3	4
VCC	—	Power supply voltage input. Bypass capacitors should be placed as close as possible to this pin and be connected directly to the ground plane.	4	5
Do	O	Internal charge pump output. Do remains on at all times	5	6
GND	—	Ground	6	7
LD	O	Lock detect, phase comparator output	7	8
fIN	I	Prescaler input. The VCO signal is AC-coupled into this pin	8	10
CLK	I	Clock input. Rising edge of the clock shifts data into the shift registers	9	11
DATA	I	Binary serial data input	10	13
LE	I	Load enable input (with internal pull up resistor). When LE is HIGH or OPEN, data stored in the shift register is transferred into the appropriate latch (depending on the level of control bit). Also, when LE is HIGH or OPEN, the output of the second internal charge pump is connected to the BISW pin	11	14
FC	I	Phase control select (with internal pull up resistor). When FC is LOW, the characteristics of the phase comparator and charge pump are reversed. FC also selects fp or fr on the fOUT pin	12	15
BISW	O	Analog switch output. When LE is HIGH or OPEN ("analog switch is ON") the output of the second charge pump is connected to the BISW pin. When LE is LOW, BISW is high impedance	13	16
fOUT	O	Phase comparator input signal. When FC is HIGH, fOUT=fr, programmable reference divider output; when FC is LOW, fOUT=fp, programmable divider output	14	17
phi P	O	Output for external charge pump. Standard CMOS output level	15	18
phi R	O	Output for external charge pump. Standard CMOS output level	16	20
NC	—	No connect	—	2, 9, 12, 19

## DATA ENTRY FORMAT

The three wire interface of DATA pin, CLK (clock) pin and LE (load enable) pin controls the serial data input of the 14-bit programmable reference divider plus the prescaler setting bit, and the 18-bit programmable divider. A rising edge of the clock shifts one bit of serial data into the internal shift registers. Depending upon the level of the control bit, stored data is transferred into the latch when load enable pin is HIGH or OPEN.

Control bit: "H" = data is transferred into 15-bit latch of programmable reference divider

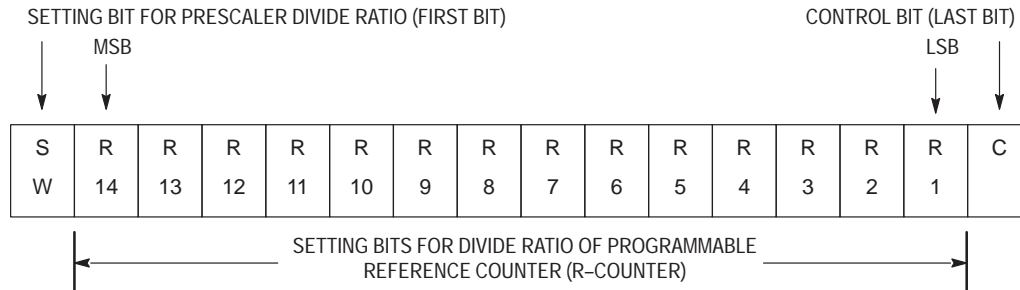

"L" = data is transferred into 18-bit latch of programmable divider

WARNING: Switching CLK or DATA after the device is programmed may generate noise on the charge pump outputs which will affect the VCO.

## PROGRAMMABLE REFERENCE DIVIDER

16-bit serial data format for the programmable reference counter, "R-counter", and prescaler select bit (SW) is shown below. If the control bit is HIGH, data is transferred from the 15-bit shift register into the 15-bit latch which specifies the R divide ratio (8 to 16383) and the prescaler divide ratio (SW=0 for  $\div 64/65$ , SW=1 for  $\div 32/33$ ). An R divide ratio less than 8 is prohibited.

For Control bit (C) = HIGH:

## DIVIDE RATIO OF PROGRAMMABLE REFERENCE (R) COUNTER

Divide Ratio R	R 14	R 13	R 12	R 11	R 10	R 9	R 8	R 7	R 6	R 5	R 4	R 3	R 2	R 1
8	0	0	0	0	0	0	0	0	0	0	1	0	0	0
9	0	0	0	0	0	0	0	0	0	0	1	0	0	1
•	•	•	•	•	•	•	•	•	•	•	•	•	•	•
16383	1	1	1	1	1	1	1	1	1	1	1	1	1	1

## PRESCALER SELECT BIT

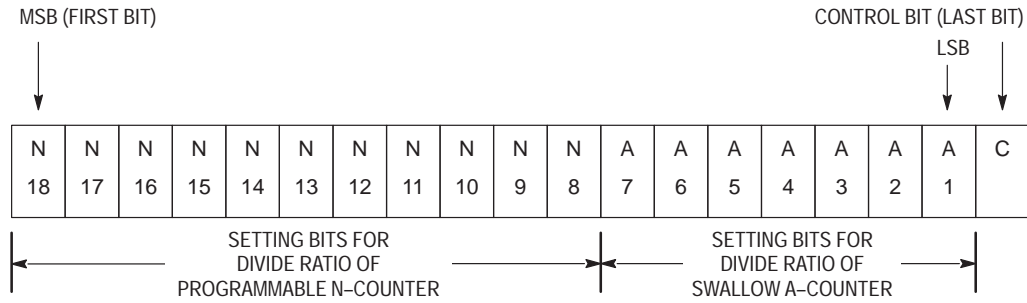

Prescaler Divide Ratio P	SW
64/65	0
32/33	1

# MC12210

## PROGRAMMABLE DIVIDER

19-bit serial data format for the programmable divider is shown below. If the control bit is LOW, data is transferred from the 18-bit shift register into the 18-bit latch which specifies the swallow A-counter divide ratio (0 to 127) and the programmable N-counter divide ratio (16 to 2047). An N-counter divide ratio less than 16 is prohibited.

For Control bit (C) = LOW:

### DIVIDE RATIO OF PROGRAMMABLE N-COUNTER

### DIVIDE RATIO OF SWALLOW A-COUNTER

Divide Ratio N	N 18	N 17	N 16	N 15	N 14	N 13	N 12	N 11	N 10	N 9	N 8	Divide Ratio A	A 7	A 6	A 5	A 4	A 3	A 2	A 1
16	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0
17	0	0	0	0	0	0	1	0	0	0	1	1	0	0	0	0	0	0	1
•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•
2047	1	1	1	1	1	1	1	1	1	1	1	127	1	1	1	1	1	1	1

## DIVIDE RATIO SETTING

$$f_{vco} = [(P \cdot N) + A] \cdot f_{osc} \div R \text{ with } A < N$$

$f_{vco}$ : Output frequency of external voltage controlled oscillator (VCO)

N: Preset divide ratio of binary 11-bit programmable counter (16 to 2047)

A: Preset divide ratio of binary 7-bit swallow counter (0 to 127,  $A < N$ )

$f_{osc}$ : Output frequency of the external frequency oscillator

R: Preset divide ratio of binary 14-bit programmable reference counter (8 to 16383)

P: Preset mode of dual modulus prescaler (32 or 64)

Figure 2. Serial Data Input Timing

NOTES: Programmable reference divider data shown in parenthesis. Data shifted into register on rising edge of CLK.

$t_s(D)$ = Setup Time DATA to CLK	$t_s(D) \geq 10$ ns
$t_h(D)$ = Hold Time DATA to CLK	$t_h(D) \geq 20$ ns

## PHASE CHARACTERISTICS/VCO CHARACTERISTICS

The phase comparator in the MC12210 is a high speed digital phase frequency detector circuit. The circuit determines the “lead” or “lag” phase relationship and time difference between the leading edges of the VCO (fp) signal and the reference (fr) input. Since these edges occur only once per cycle, the detector has a range of  $\pm 2\pi$  radians. The phase comparator outputs are standard CMOS rail-to-rail levels ( $V_P$  to GND for  $\phi_P$  and  $V_{CC}$  to GND for  $\phi_R$ ), designed for up to 20MHz operation into a 15pF load. These phase comparator outputs can be used along with an external charge pump to enhance the PLL characteristics.

The operation of the phase comparator is shown in Figures 3 and 5. The phase characteristics of the phase comparator are controlled by the FC pin. The polarity of the phase comparator outputs,  $\phi_R$  and  $\phi_P$ , as well as the charge pump output Do can be reversed by switching the FC pin.

**Figure 3. Phase/Frequency Detector, Internal Charge Pump and Lock Detect Waveforms**

NOTES: Do and BISW are current outputs.  
 Phase difference detection range:  $-2\pi$  to  $+2\pi$   
 Spike difference depends on charge pump characteristics. Also, the spike is output in order to diminish dead band.  
 When  $f_r > f_p$  or  $f_r < f_p$ , spike might not appear depending upon charge pump characteristics.

$$\text{Internal Charge Pump Gain} \approx \left| \frac{I_{\text{source}} + I_{\text{sink}}}{4\pi} \right| = \frac{4\text{mA}}{4\pi}$$

**For FC = HIGH:**

**fr lags fp in phase OR fp > fr in frequency**

When the phase of fr lags that of fp or the frequency of fp is greater than fr, the φP output will remain in a HIGH state while the φR output will pulse from LOW to HIGH. The output pulse will reach a minimum 50% duty cycle under a 180° out of phase condition. The signal on φR indicates to the VCO to decrease in frequency to bring the loop into lock.

**fr leads fp in phase OR fp < fr in frequency**

When the phase of fr leads that of fp or the frequency of fp is less than fr, the φR output will remain in a LOW state while the φP output pulses from HIGH to LOW. The output pulse will reach a minimum 50% duty cycle under a 180° out of phase condition. The signal on φP indicates to the VCO to increase in frequency to bring the loop to lock.

**fr = fp in phase and frequency**

When the phase and frequency of fr and fp are equal, the output φP will remain in a HIGH state and φR will remain in a LOW state except for voltage spikes when signals are in phase. This situation indicates that the loop is in lock and the phase comparator will maintain the loop in its locked state.

When FC = LOW, the operation of the phase comparator is reversed from the above explanation.

**For FC = LOW:**

**fr lags fp in phase OR fp > fr in frequency**

When the phase of fr lags that of fp or the frequency of fp is greater than fr, the φR output will remain in a LOW state while the φP output will pulse from HIGH to LOW. The output pulse will reach a minimum 50% duty cycle under a 180° out of phase condition. The signal on φP indicates to the VCO to increase in frequency to bring the loop into lock.

**fr leads fp in phase OR fp < fr in frequency**

When the phase of fr leads that of fp or the frequency of fp is less than fr, the φP output will remain in a HIGH state while the φR output pulses from LOW to HIGH. The output pulse will reach a minimum 50% duty cycle under a 180° out of phase condition. The signal on φR indicates to the VCO to decrease in frequency to bring the loop to lock.

**fr = fp in phase and frequency**

When the phase and frequency of fr and fp are equal, the output φP will remain in a HIGH state and φR will remain in a LOW state except for voltage spikes when signals are in phase. This situation indicates that the loop is in lock and the phase comparator will maintain the loop in its locked state.

The FC pin controls not only the phase characteristics, but also controls the f<sub>OUT</sub> test pin. The FC pin permits the user to monitor either of the phase comparator input signals, fr or fp, at the f<sub>OUT</sub> output providing a test mode where the programming of the dividers and the output of the counters can be checked. When FC is HIGH, f<sub>OUT</sub> = fr, the programmable reference divider output. When FC is LOW, f<sub>OUT</sub> = fp, the programmable divider output.

Hence,

If VCO characteristics are like (1), FC should be set HIGH or OPEN.  $f_{OUT} = fr$

If VCO characteristics are like (2), FC should be set LOW.  $f_{OUT} = fp$

Figure 4. VCO Characteristics

Figure 5. Phase Comparator, Internal Charge Pump, and f<sub>OUT</sub> Characteristics

	FC = HIGH or OPEN				FC = LOW			
	Do	φR	φP	f <sub>OUT</sub>	Do	φR	φP	f <sub>OUT</sub>
fp < fr	H	L	L	fr	L	H	H	fp
fp > fr	L	H	H	fr	H	L	L	fp
fp = fr	Z	L	H	fr	Z	L	H	fp

NOTES: Z = High impedance  
When LE is HIGH or Open, BISW has the same characteristics as Do.

# MC12210

Figure 6. Detailed Phase Comparator Block Diagram

## LOCK DETECT

The Lock Detect (LD) output pin provides a LOW pulse when  $f_r$  and  $f_p$  are not equal in phase or frequency. The output is normally HIGH. LD is designed to be the logical NORing of the phase frequency detector's outputs UP and DOWN. See Figure 6. In typical applications the output signal drives external circuitry which provides a steady LOW signal when the loop is locked. See Figure 9.

## OSCILLATOR INPUT

For best operation, an external reference oscillator is recommended. The signal should be AC-coupled to the OSCin pin through a coupling capacitor. In this case, no connection to OSCout is required. The magnitude of the AC-coupled signal must be between 500 and 2200 mV peak-to-peak. To optimize the phase noise of the PLL when used in this mode, the input signal amplitude should be closer to the upper specification limit. This maximizes the slew rate of the signal as it switches against the internal voltage reference.

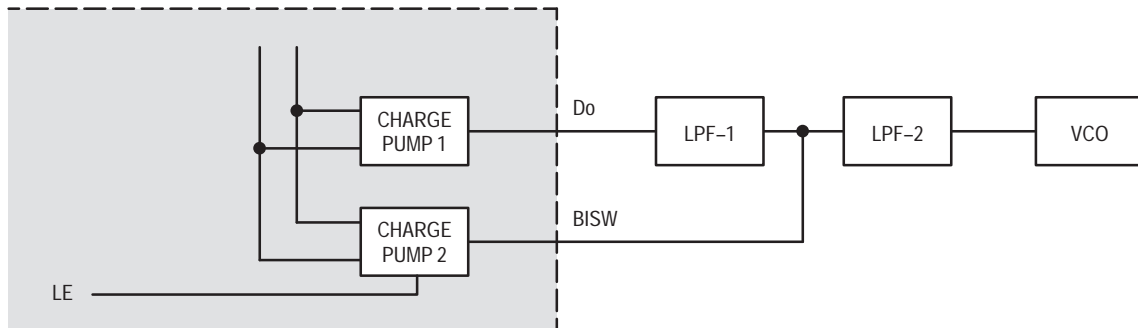

The device incorporates an on-chip reference oscillator/buffer so that an external parallel-resonant fundamental crystal can be connected between OSCin and OSCout. External capacitor C1 and C2 as shown in Figure 10 are required to set the proper crystal load capacitance and oscillator frequency. The values of the capacitors are dependent on the crystal chosen (up to a maximum of 30 pF each including parasitic and stray capacitance). However, using the on-chip reference oscillator greatly increases the synthesized phase noise.

## DUAL INTERNAL CHARGE PUMPS ("ANALOG SWITCH")

Due to the pure Bipolar nature of the MC12210 design, the "analog switch" function is implemented with dual internal charge pumps. The loop filter time constant can be decreased by bypassing the first stage of the loop filter with the charge pump output BISW as shown in Figure 7 below. This enables the VCO to lock in a shorter amount of time.

When LE is HIGH or OPEN ("analog switch is ON"), the output of the second internal charge pump is connected to the BISW pin, and the Do output is ON. The charge pump 2 output on BISW is essentially equal to the charge pump 1 output on Do. When LE is LOW, BISW is in a high impedance state and Do output is active.

# Phase-Frequency Detector

The MCH/K12140 is a phase frequency-detector intended for phase-locked loop applications which require a minimum amount of phase and frequency difference at lock. When used in conjunction with the MC12147, MC12148 or MC12149 VCO, a high bandwidth PLL can be realized. The device is functionally compatible with the MC12040 phase-frequency detector, however the MOSAIC™ III process is used to push the maximum frequency to 800 MHz and significantly reduce the dead zone of the detector. When the Reference (R) and VCO (V) inputs are unequal in frequency and/or phase, the differential UP (U) and DOWN (D) outputs will provide pulse streams which when subtracted and integrated provide an error voltage for control of a VCO.

The device is packaged in a small outline, surface mount 8-lead SOIC package. There are two versions of the device to provide I/O compatibility to the two existing ECL standards. The MCH12140 is compatible with MECL10H™ logic levels while the MCK12140 is compatible to 100K ECL logic levels. This device can also be used in +5.0 V systems. Please refer to Motorola Application Note AN1406/D, "Designing with PECL (ECL at +5.0 V)" for more information.

- 800 MHz Typical Bandwidth
- Small Outline 8-Lead SOIC Package
- 75 kΩ Internal Input Pulldown Resistors
- >1000 V ESD Protection

For proper operation, the input edge rate of the R and V inputs should be less than 5ns.

MOSAIC III and MECL 10H are trademarks of Motorola

## APPLICATIONS INFORMATION

The 12140 is a high speed digital circuit used as a phase comparator in an analog phase-locked loop. The device determines the "lead" or "lag" phase relationship and time difference between the leading edges of a VCO (V) signal and a Reference (R) input. Since these edges occur only once per cycle, the detector has a range of  $\pm 2\pi$  radians.

The operation of the 12140 can best be described using the plots of Figure 1. Figure 1 plots the average value of  $\bar{U}$ ,  $\bar{D}$  and the difference between  $\bar{U}$  and  $\bar{D}$  versus the phase difference between the V and R inputs.

There are four potential relationships between V and R: R lags or leads V and the frequency of R is less than or greater than the frequency of V. Under these four conditions the 12140 will function as follows:

### R lags V in phase

When the R and V inputs are equal in frequency and the phase of R lags that of V the  $\bar{D}$  output will stay HIGH while the  $\bar{U}$  output will pulse from HIGH to LOW. The magnitude of the pulse will be proportional to the phase difference between the V and R inputs reaching a minimum 50% duty cycle under a  $180^\circ$  out of phase condition. The signal on  $\bar{D}$  indicates to the VCO to decrease in frequency to bring the loop into lock.

### V frequency > R frequency

When the frequency of V is greater than that of R the 12140 behaves in a similar fashion as above. Again the signal on  $\bar{D}$  indicates that the VCO frequency must be decreased to bring the loop into lock.

### R leads V in phase

When the R and V inputs are equal in frequency and the phase of R leads that of V the  $\bar{U}$  output pulses from HIGH to LOW. The magnitude of the pulse will be proportional to the phase difference between the V and R inputs reaching a minimum 50% duty cycle under a  $180^\circ$  out of phase condition. The signal on  $\bar{U}$  indicates to the VCO to increase in frequency to bring the loop into lock.

### V frequency < R frequency

When the frequency of V is less than that of R the 12140 behaves in a similar fashion as above. Again the signal on  $\bar{U}$  indicates that the VCO frequency must be decreased to bring the loop into lock.

From Figure 1 when V and R are at the same frequency and in phase the value of  $\bar{U} - \bar{D}$  is zero thus providing a zero error voltage to the VCO. This situation indicates the loop is in lock and the 12140 action will maintain the loop in its locked state.

**Figure 1. Average Output Voltage versus Phase Difference**

# PLL Frequency Synthesizer Family

## CMOS

**MC145151-2**  
**MC145152-2**  
**MC145157-2**  
**MC145158-2**

The devices described in this document are typically used as low-power, phase-locked loop frequency synthesizers. When combined with an external low-pass filter and voltage-controlled oscillator, these devices can provide all the remaining functions for a PLL frequency synthesizer operating up to the device's frequency limit. For higher VCO frequency operation, a down mixer or a prescaler can be used between the VCO and the synthesizer IC.

These frequency synthesizer chips can be found in the following and other applications:

CATV  
AM/FM Radios  
Two-Way Radios

TV Tuning  
Scanning Receivers  
Amateur Radio

## MC145151-2

# Parallel-Input PLL Frequency Synthesizer

## Interfaces with Single-Modulus Prescalers

The MC145151-2 is programmed by 14 parallel-input data lines for the N counter and three input lines for the R counter. The device features consist of a reference oscillator, selectable-reference divider, digital-phase detector, and 14-bit programmable divide-by-N counter.

The MC145151-2 is an improved-performance drop-in replacement for the MC145151-1. The power consumption has decreased and ESD and latch-up performance have improved.

- Operating Temperature Range: - 40 to 85°C
- Low Power Consumption Through Use of CMOS Technology
- 3.0 to 9.0 V Supply Range
- On- or Off-Chip Reference Oscillator Operation
- Lock Detect Signal
- ÷ N Counter Output Available
- Single Modulus/Parallel Programming
- 8 User-Selectable ÷ R Values: 8, 128, 256, 512, 1024, 2048, 2410, 8192
- ÷ N Range = 3 to 16383
- "Linearized" Digital Phase Detector Enhances Transfer Function Linearity
- Two Error Signal Options: Single-Ended (Three-State) or Double-Ended
- Chip Complexity: 8000 FETs or 2000 Equivalent Gates

## MC145151-2 BLOCK DIAGRAM

NOTE: N0 – N13 inputs and inputs RA0, RA1, and RA2 have pull-up resistors that are not shown.

## PIN DESCRIPTIONS

### INPUT PINS

#### $f_{in}$ Frequency Input (Pin 1)

Input to the  $\div N$  portion of the synthesizer.  $f_{in}$  is typically derived from loop VCO and is ac coupled into the device. For larger amplitude signals (standard CMOS logic levels) dc coupling may be used.

#### RA0 – RA2 Reference Address Inputs (Pins 5, 6, 7)

These three inputs establish a code defining one of eight possible divide values for the total reference divider, as defined by the table below.

Pull-up resistors ensure that inputs left open remain at a logic 1 and require only a SPST switch to alter data to the zero state.

Reference Address Code			Total Divide Value
RA2	RA1	RA0	
0	0	0	8
0	0	1	128
0	1	0	256
0	1	1	512
1	0	0	1024
1	0	1	2048
1	1	0	2410
1	1	1	8192

#### N0 – N11 N Counter Programming Inputs (Pins 11 – 20, 22 – 25)

These inputs provide the data that is preset into the  $\div N$  counter when it reaches the count of zero. N0 is the least significant and N13 is the most significant. Pull-up resistors en-

sure that inputs left open remain at a logic 1 and require only an SPST switch to alter data to the zero state.

#### T/R Transmit/Receive Offset Adder Input (Pin 21)

This input controls the offset added to the data provided at the N inputs. This is normally used for offsetting the VCO frequency by an amount equal to the IF frequency of the transceiver. This offset is fixed at 856 when T/R is low and gives no offset when T/R is high. A pull-up resistor ensures that no connection will appear as a logic 1 causing no offset addition.

#### OSCin, OSCout Reference Oscillator Input/Output (Pins 27, 26)

These pins form an on-chip reference oscillator when connected to terminals of an external parallel resonant crystal. Frequency setting capacitors of appropriate value must be connected from OSCin to ground and OSCout to ground. OSCin may also serve as the input for an externally-generated reference signal. This signal is typically ac coupled to OSCin, but for larger amplitude signals (standard CMOS logic levels) dc coupling may also be used. In the external reference mode, no connection is required to OSCout.

### OUTPUT PINS

#### PDout Phase Detector A Output (Pin 4)

Three-state output of phase detector for use as loop-error signal. Double-ended outputs are also available for this purpose (see  $\phi_V$  and  $\phi_R$ ).

Frequency  $f_V > f_R$  or  $f_V$  Leading: Negative Pulses

Frequency  $f_V < f_R$  or  $f_V$  Lagging: Positive Pulses

Frequency  $f_V = f_R$  and Phase Coincidence: High-Impedance State

$\phi_R$ ,  $\phi_V$

### Phase Detector B Outputs (Pins 8, 9)

These phase detector outputs can be combined externally for a loop-error signal. A single-ended output is also available for this purpose (see **PD<sub>out</sub>**).

If frequency  $f_V$  is greater than  $f_R$  or if the phase of  $f_V$  is leading, then error information is provided by  $\phi_V$  pulsing low.  $\phi_R$  remains essentially high.

If the frequency  $f_V$  is less than  $f_R$  or if the phase of  $f_V$  is lagging, then error information is provided by  $\phi_R$  pulsing low.  $\phi_V$  remains essentially high.

If the frequency of  $f_V = f_R$  and both are in phase, then both  $\phi_V$  and  $\phi_R$  remain high except for a small minimum time period when both pulse low in phase.

$f_V$

### N Counter Output (Pin 10)

This is the buffered output of the  $\div N$  counter that is inter-

nally connected to the phase detector input. With this output available, the  $\div N$  counter can be used independently.

**LD**

### Lock Detector Output (Pin 28)

Essentially a high level when loop is locked ( $f_R$ ,  $f_V$  of same phase and frequency). Pulses low when loop is out of lock.

### POWER SUPPLY

**V<sub>DD</sub>**

### Positive Power Supply (Pin 3)

The positive power supply potential. This pin may range from +3 to +9 V with respect to  $V_{SS}$ .

**V<sub>SS</sub>**

### Negative Power Supply (Pin 2)

The most negative supply potential. This pin is usually ground.

## TYPICAL APPLICATIONS

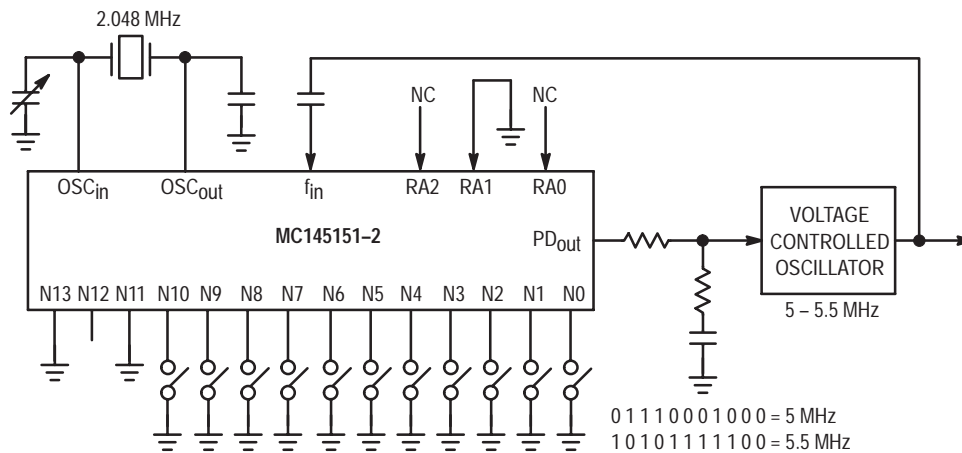

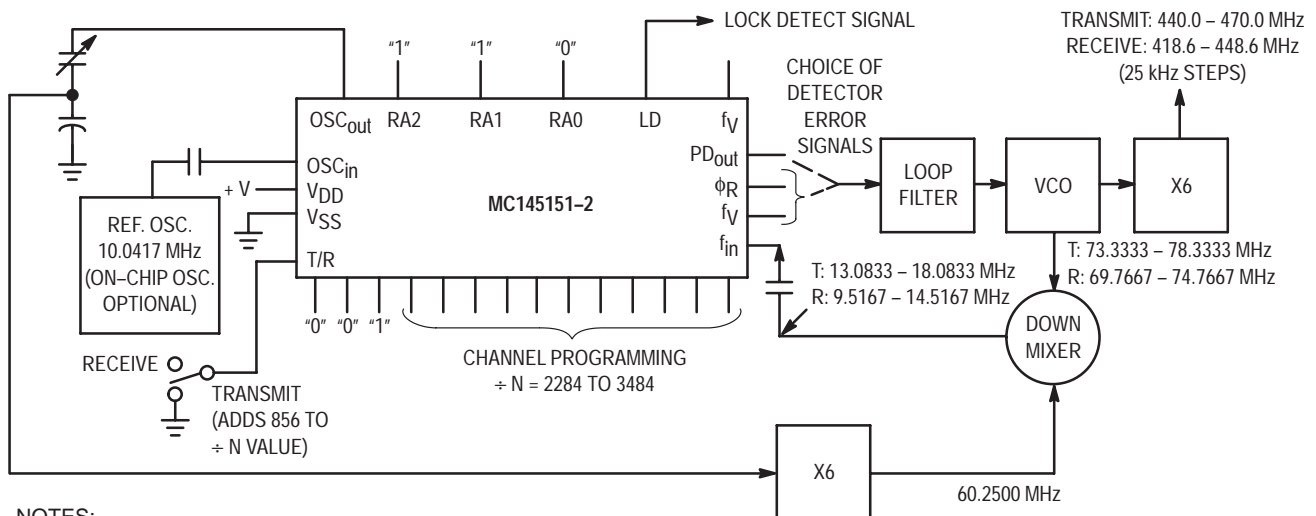

Figure 1. 5 MHz to 5.5 MHz Local Oscillator Channel Spacing = 1 kHz

#### NOTES:

- $f_R = 4.1667$  kHz;  $\div R = 2410$ ; 21.4 MHz low side injection during receive.
- Frequency values shown are for the 440 – 470 MHz band. Similar implementation applies to the 406 – 440 MHz band. For 470 – 512 MHz, consider reference oscillator frequency X9 for mixer injection signal (90.3750 MHz).

MC145151-2 Data Sheet Continued on Page 4.2-118

## MC145152-2

# Parallel-Input PLL Frequency Synthesizer

## Interfaces with Dual-Modulus Prescalers

The MC145152-2 is programmed by sixteen parallel inputs for the N and A counters and three input lines for the R counter. The device features consist of a reference oscillator, selectable-reference divider, two-output phase detector, 10-bit programmable divide-by-N counter, and 6-bit programmable ÷ A counter.

The MC145152-2 is an improved-performance drop-in replacement for the MC145152-1. Power consumption has decreased and ESD and latch-up performance have improved.

- Operating Temperature Range: – 40 to 85°C
- Low Power Consumption Through Use of CMOS Technology
- 3.0 to 9.0 V Supply Range
- On- or Off-Chip Reference Oscillator Operation
- Lock Detect Signal
- Dual Modulus/Parallel Programming
- 8 User-Selectable ÷ R Values: 8, 64, 128, 256, 512, 1024, 1160, 2048
- ÷ N Range = 3 to 1023, ÷ A Range = 0 to 63
- Chip Complexity: 8000 FETs or 2000 Equivalent Gates
- See Application Note AN980

## MC145152-2 BLOCK DIAGRAM

NOTE: N0 – N9, A0 – A5, and RA0 – RA2 have pull-up resistors that are not shown.

## PIN DESCRIPTIONS

### INPUT PINS

#### $f_{in}$ Frequency Input (Pin 1)

Input to the positive edge triggered  $\div N$  and  $\div A$  counters.  $f_{in}$  is typically derived from a dual-modulus prescaler and is ac coupled into the device. For larger amplitude signals (standard CMOS logic levels) dc coupling may be used.

#### RA0, RA1, RA2 Reference Address Inputs (Pins 4, 5, 6)

These three inputs establish a code defining one of eight possible divide values for the total reference divider. The total reference divide values are as follows:

Reference Address Code			Total Divide Value
RA2	RA1	RA0	
0	0	0	8
0	0	1	64
0	1	0	128
0	1	1	256
1	0	0	512
1	0	1	1024
1	1	0	1160
1	1	1	2048

#### N0 – N9 N Counter Programming Inputs (Pins 11 – 20)

The N inputs provide the data that is preset into the  $\div N$  counter when it reaches the count of 0. N0 is the least significant digit and N9 is the most significant. Pull-up resistors ensure that inputs left open remain at a logic 1 and require only a SPST switch to alter data to the zero state.

#### A0 – A5 A Counter Programming Inputs (Pins 23, 21, 22, 24, 25, 10)

The A inputs define the number of clock cycles of  $f_{in}$  that require a logic 0 on the MC output (see **Dual-Modulus**

**Prescaling** section). The A inputs all have internal pull-up resistors that ensure that inputs left open will remain at a logic 1.

#### OSCin, OSCout Reference Oscillator Input/Output (Pins 27, 26)

These pins form an on-chip reference oscillator when connected to terminals of an external parallel resonant crystal. Frequency setting capacitors of appropriate value must be connected from OSCin to ground and OSCout to ground. OSCin may also serve as the input for an externally-generated reference signal. This signal is typically ac coupled to OSCin, but for larger amplitude signals (standard CMOS logic levels) dc coupling may also be used. In the external reference mode, no connection is required to OSCout.

### OUTPUT PINS

#### $\phi_R$ , $\phi_V$ Phase Detector B Outputs (Pins 7, 8)

These phase detector outputs can be combined externally for a loop-error signal.

If the frequency  $f_V$  is greater than  $f_R$  or if the phase of  $f_V$  is leading, then error information is provided by  $\phi_V$  pulsing low.  $\phi_R$  remains essentially high.

If the frequency  $f_V$  is less than  $f_R$  or if the phase of  $f_V$  is lagging, then error information is provided by  $\phi_R$  pulsing low.  $\phi_V$  remains essentially high.

If the frequency of  $f_V = f_R$  and both are in phase, then both  $\phi_V$  and  $\phi_R$  remain high except for a small minimum time period when both pulse low in phase.

#### MC Dual-Modulus Prescale Control Output (Pin 9)

Signal generated by the on-chip control logic circuitry for controlling an external dual-modulus prescaler. The MC level will be low at the beginning of a count cycle and will remain low until the  $\div A$  counter has counted down from its programmed value. At this time, MC goes high and remains high until the  $\div N$  counter has counted the rest of the way down from its programmed value ( $N - A$  additional counts since both  $\div N$  and  $\div A$  are counting down during the first

portion of the cycle). MC is then set back low, the counters preset to their respective programmed values, and the above sequence repeated. This provides for a total programmable divide value ( $N_T$ ) =  $N \cdot P + A$  where P and P + 1 represent the dual-modulus prescaler divide values respectively for high and low MC levels, N the number programmed into the  $\div N$  counter, and A the number programmed into the  $\div A$  counter.

**LD**  
**Lock Detector Output (Pin 28)**

Essentially a high level when loop is locked ( $f_R$ ,  $f_V$  of same phase and frequency). Pulses low when loop is out of lock.

**POWER SUPPLY**

**V<sub>DD</sub>**  
**Positive Power Supply (Pin 3)**

The positive power supply potential. This pin may range from + 3 to + 9 V with respect to V<sub>SS</sub>.

**V<sub>SS</sub>**  
**Negative Power Supply (Pin 2)**

The most negative supply potential. This pin is usually ground.

**TYPICAL APPLICATIONS**

**NOTES:**

1. Off-chip oscillator optional.
2. The  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information. The  $\phi_R$  and  $\phi_V$  outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp used in the combiner/loop filter.

**Figure 1. Synthesizer for Land Mobile Radio VHF Bands**

**NOTES:**

1. Receiver 1st I.F. = 45 MHz, low side injection; Receiver 2nd I.F. = 11.7 MHz, low side injection.
2. Duplex operation with 45 MHz receiver/transmit separation.
3.  $f_R = 7.5 \text{ kHz}$ ;  $\div R = 2048$ .
4.  $N_{\text{total}} = N \cdot 64 + A = 27501 \text{ to } 28166$ ;  $N = 429 \text{ to } 440$ ;  $A = 0 \text{ to } 63$ .
5. MC145158-2 may be used where serial data entry is desired.
6. High frequency prescalers (e.g., MC12018 [520 MHz] and MC12022 [1 GHz]) may be used for higher frequency VCO and  $f_{\text{ref}}$  implementations.
7. The  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information. The  $\phi_R$  and  $\phi_V$  outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp used in the combiner/loop filter.

## MC145157-2

# Serial-Input PLL Frequency Synthesizer

## Interfaces with Single-Modulus Prescalers

The MC145157-2 has a fully programmable 14-bit reference counter, as well as a fully programmable  $\div N$  counter. The counters are programmed serially through a common data input and latched into the appropriate counter latch, according to the last data bit (control bit) entered.

The MC145157-2 is an improved-performance drop-in replacement for the MC145157-1. Power consumption has decreased and ESD and latch-up performance have improved.

- Operating Temperature Range:  $-40$  to  $85^{\circ}\text{C}$
- Low Power Consumption Through Use of CMOS Technology
- 3.0 to 9.0 V Supply Range
- Fully Programmable Reference and  $\div N$  Counters
- $\div R$  Range = 3 to 16383
- $\div N$  Range = 3 to 16383
- $f_V$  and  $f_R$  Outputs
- Lock Detect Signal
- Compatible with the Serial Peripheral Interface (SPI) on CMOS MCUs
- "Linearized" Digital Phase Detector
- Single-Ended (Three-State) or Double-Ended Phase Detector Outputs
- Chip Complexity: 6504 FETs or 1626 Equivalent Gates

## MC145157-2 BLOCK DIAGRAM

## PIN DESCRIPTIONS

### INPUT PINS

#### $f_{in}$ Frequency Input (Pin 8)

Input frequency from VCO output. A rising edge signal on this input decrements the  $\div N$  counter. This input has an inverter biased in the linear region to allow use with ac coupled signals as low as 500 mV p-p. For larger amplitude signals (standard CMOS logic levels), dc coupling may be used.

#### CLK, DATA Shift Clock, Serial Data Inputs (Pins 9, 10)

Each low-to-high transition of the clock shifts one bit of data into the on-chip shift registers. The last data bit entered determines which counter storage latch is activated; a logic 1 selects the reference counter latch and a logic 0 selects the  $\div N$  counter latch. The entry format is as follows:

#### ENB Latch Enable Input (Pin 11)

A logic high on this pin latches the data from the shift register into the reference divider or  $\div N$  latches depending on the control bit. The reference divider latches are activated if the control bit is at a logic high and the  $\div N$  latches are activated

if the control bit is at a logic low. A logic low on this pin allows the user to change the data in the shift registers without affecting the counters. ENB is normally low and is pulsed high to transfer data to the latches.

#### OSCin, OSCout Reference Oscillator Input/Output (Pins 1, 2)

These pins form an on-chip reference oscillator when connected to terminals of an external parallel resonant crystal. Frequency setting capacitors of appropriate value must be connected from OSCin to ground and OSCout to ground. OSCin may also serve as the input for an externally-generated reference signal. This signal is typically ac coupled to OSCin, but for larger amplitude signals (standard CMOS logic levels) dc coupling may also be used. In the external reference mode, no connection is required to OSCout.

### OUTPUT PINS

#### PDout Single-Ended Phase Detector A Output (Pin 5)

This single-ended (three-state) phase detector output produces a loop-error signal that is used with a loop filter to control a VCO.

- Frequency  $f_V > f_R$  or  $f_V$  Leading: Negative Pulses
- Frequency  $f_V < f_R$  or  $f_V$  Lagging: Positive Pulses
- Frequency  $f_V = f_R$  and Phase Coincidence: High-Impedance State

#### $\phi_R, \phi_V$ Double-Ended Phase Detector B Outputs (Pins 16, 15)

These outputs can be combined externally for a loop-error signal. A single-ended output is also available for this purpose (see PDout).

If frequency  $f_V$  is greater than  $f_R$  or if the phase of  $f_V$  is leading, then error information is provided by  $\phi_V$  pulsing low.  $\phi_R$  remains essentially high.

If the frequency  $f_V$  is less than  $f_R$  or if the phase of  $f_V$  is lagging, then error information is provided by  $\phi_R$  pulsing low.  $\phi_V$  remains essentially high.

If the frequency of  $f_V = f_R$  and both are in phase, then both  $\phi_V$  and  $\phi_R$  remain high except for a small minimum time period when both pulse low in phase.

#### **$f_R, f_V$**

#### **R Counter Output, N Counter Output (Pins 13, 3)**

Buffered, divided reference and  $f_{in}$  frequency outputs. The  $f_R$  and  $f_V$  outputs are connected internally to the  $\div R$  and  $\div N$  counter outputs respectively, allowing the counters to be used independently, as well as monitoring the phase detector inputs.

#### **LD**

#### **Lock Detector Output (Pin 7)**

This output is essentially at a high level when the loop is locked ( $f_R, f_V$  of same phase and frequency), and pulses low when loop is out of lock.

#### **REF<sub>out</sub>**

#### **Buffered Reference Oscillator Output (Pin 14)**

This output can be used as a second local oscillator, reference oscillator to another frequency synthesizer, or as the system clock to a microprocessor controller.

#### **S/R<sub>out</sub>**

#### **Shift Register Output (Pin 12)**

This output can be connected to an external shift register to provide band switching, control information, and counter programming code checking.

#### **POWER SUPPLY**

#### **V<sub>DD</sub>**

#### **Positive Power Supply (Pin 4)**

The positive power supply potential. This pin may range from +3 to +9 V with respect to  $V_{SS}$ .

#### **V<sub>SS</sub>**

#### **Negative Power Supply (Pin 6)**

The most negative supply potential. This pin is usually ground.

## MC145158-2

# Serial-Input PLL Frequency Synthesizer

## Interfaces with Dual-Modulus Prescalers

The MC145158-2 has a fully programmable 14-bit reference counter, as well as fully programmable  $\div N$  and  $\div A$  counters. The counters are programmed serially through a common data input and latched into the appropriate counter latch, according to the last data bit (control bit) entered.

The MC145158-2 is an improved-performance drop-in replacement for the MC145158-1. Power consumption has decreased and ESD and latch-up performance have improved.

- Operating Temperature Range:  $-40$  to  $85^{\circ}\text{C}$
- Low Power Consumption Through Use of CMOS Technology
- 3.0 to 9.0 V Supply Range
- Fully Programmable Reference and  $\div N$  Counters
- $\div R$  Range = 3 to 16383
- $\div N$  Range = 3 to 1023
- Dual Modulus Capability;  $\div A$  Range = 0 to 127
- $f_V$  and  $f_R$  Outputs
- Lock Detect Signal
- Compatible with the Serial Peripheral Interface (SPI) on CMOS MCUs
- "Linearized" Digital Phase Detector
- Single-Ended (Three-State) or Double-Ended Phase Detector Outputs

## OUTPUT PINS

### PD<sub>out</sub>

#### Phase Detector A Output (Pin 5)

This single-ended (three-state) phase detector output produces a loop-error signal that is used with a loop filter to control a VCO.

Frequency  $f_V > f_R$  or  $f_V$  Leading: Negative Pulses

Frequency  $f_V < f_R$  or  $f_V$  Lagging: Positive Pulses

Frequency  $f_V = f_R$  and Phase Coincidence: High-Impedance State

### $\phi_R, \phi_V$

#### Phase Detector B Outputs (Pins 16, 15)

Double-ended phase detector outputs. These outputs can be combined externally for a loop-error signal. A single-ended output is also available for this purpose (see PD<sub>out</sub>).

If frequency  $f_V$  is greater than  $f_R$  or if the phase of  $f_V$  is leading, then error information is provided by  $\phi_V$  pulsing low.  $\phi_R$  remains essentially high.

If the frequency  $f_V$  is less than  $f_R$  or if the phase of  $f_V$  is lagging, then error information is provided by  $\phi_R$  pulsing low.  $\phi_V$  remains essentially high.

If the frequency of  $f_V = f_R$  and both are in phase, then both  $\phi_V$  and  $\phi_R$  remain high except for a small minimum time period when both pulse low in phase.

### MC

#### Dual-Modulus Prescale Control Output (Pin 12)

This output generates a signal by the on-chip control logic circuitry for controlling an external dual-modulus prescaler. The MC level is low at the beginning of a count cycle and remains low until the  $\div A$  counter has counted down from its programmed value. At this time, MC goes high and remains high until the  $\div N$  counter has counted the rest of the way down from its programmed value ( $N - A$  additional counts since both  $\div N$  and  $\div A$  are counting down during the first portion of the cycle). MC is then set back low, the counters preset to their respective programmed values, and the above sequence repeated. This provides for a total programmable divide value ( $N_T$ ) =  $N \cdot P + A$  where  $P$  and  $P + 1$  represent the

dual-modulus prescaler divide values respectively for high and low modulus control levels,  $N$  the number programmed into the  $\div N$  counter, and  $A$  the number programmed into the  $\div A$  counter. Note that when a prescaler is needed, the dual-modulus version offers a distinct advantage. The dual-modulus prescaler allows a higher reference frequency at the phase detector input, increasing system performance capability, and simplifying the loop filter design.

### $f_R, f_V$

#### R Counter Output, N Counter Output (Pins 13, 3)

Buffered, divided reference and  $f_{in}$  frequency outputs. The  $f_R$  and  $f_V$  outputs are connected internally to the  $\div R$  and  $\div N$  counter outputs respectively, allowing the counters to be used independently, as well as monitoring the phase detector inputs.

### LD

#### Lock Detector Output (Pin 7)

This output is essentially at a high level when the loop is locked ( $f_R, f_V$  of same phase and frequency), and pulses low when loop is out of lock.

### REF<sub>out</sub>

#### Buffered Reference Oscillator Output (Pin 14)

This output can be used as a second local oscillator, reference oscillator to another frequency synthesizer, or as the system clock to a microprocessor controller.

## POWER SUPPLY

### V<sub>DD</sub>

#### Positive Power Supply (Pin 4)

The positive power supply potential. This pin may range from +3 to +9 V with respect to V<sub>SS</sub>.

### V<sub>SS</sub>

#### Negative Power Supply (Pin 6)

The most negative supply potential. This pin is usually ground.

## MC14515X–2 FAMILY CHARACTERISTICS AND DESCRIPTIONS

### MAXIMUM RATINGS\* (Voltages Referenced to $V_{SS}$ )

Symbol	Parameter	Value	Unit
$V_{DD}$	DC Supply Voltage	– 0.5 to + 10.0	V
$V_{in}$ , $V_{out}$	Input or Output Voltage (DC or Transient) except SW1, SW2	– 0.5 to $V_{DD} + 0.5$	V
$V_{out}$	Output Voltage (DC or Transient), SW1, SW2 ( $R_{pull-up} = 4.7\text{ k}\Omega$ )	– 0.5 to + 15	V
$I_{in}$ , $I_{out}$	Input or Output Current (DC or Transient), per Pin	$\pm 10$	mA
$I_{DD}$ , $I_{SS}$	Supply Current, $V_{DD}$ or $V_{SS}$ Pins	$\pm 30$	mA
$P_D$	Power Dissipation, per Package†	500	mW
$T_{stg}$	Storage Temperature	– 65 to + 150	°C
$T_L$	Lead Temperature, 1 mm from Case for 10 seconds	260	°C

\* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.

† Power Dissipation Temperature Derating:

Plastic DIP: – 12 mW/°C from 65 to 85°C

SOG Package: – 7 mW/°C from 65 to 85°C

These devices contain protection circuitry to protect against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to these high-impedance circuits. For proper operation,  $V_{in}$  and  $V_{out}$  should be constrained to the range  $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{DD}$  except for SW1 and SW2.

SW1 and SW2 can be tied through external resistors to voltages as high as 15 V, independent of the supply voltage.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either  $V_{SS}$  or  $V_{DD}$ ), except for inputs with pull-up devices. Unused outputs must be left open.

**FREQUENCY CHARACTERISTICS** (Voltages References to  $V_{SS}$ ,  $C_L = 50$  pF, Input  $t_r = t_f = 10$  ns unless otherwise indicated)

Symbol	Parameter	Test Condition	$V_{DD}$ V	- 40°C		25°C		85°C		Unit
				Min	Max	Min	Max	Min	Max	
$f_i$	Input Frequency ( $f_{in}$ , $OSC_{in}$ )	$R \geq 8, A \geq 0, N \geq 8$ $V_{in} = 500$ mV p-p ac coupled sine wave	3	—	6	—	6	—	6	MHz
			5	—	15	—	15	—	15	
			9	—	15	—	15	—	15	
		$R \geq 8, A \geq 0, N \geq 8$ $V_{in} = 1$ V p-p ac coupled sine wave	3	—	12	—	12	—	7	MHz
			5	—	22	—	20	—	20	
			9	—	25	—	22	—	22	
		$R \geq 8, A \geq 0, N \geq 8$ $V_{in} = V_{DD}$ to $V_{SS}$ dc coupled square wave	3	—	13	—	12	—	8	MHz
			5	—	25	—	22	—	22	
			9	—	25	—	25	—	25	

NOTE: Usually, the PLL's propagation delay from  $f_{in}$  to MC plus the setup time of the prescaler determines the upper frequency limit of the system. The upper frequency limit is found with the following formula:  $f = P / (t_p + t_{set})$  where  $f$  is the upper frequency in Hz,  $P$  is the lower of the dual modulus prescaler ratios,  $t_p$  is the  $f_{in}$  to MC propagation delay in seconds, and  $t_{set}$  is the prescaler setup time in seconds. For example, with a 5 V supply, the  $f_{in}$  to MC delay is 70 ns. If the MC12028A prescaler is used, the setup time is 16 ns. Thus, if the 64/65 ratio is utilized, the upper frequency limit is  $f = P / (t_p + t_{set}) = 64 / (70 + 16) = 744$  MHz.

$V_H$  = High Voltage Level.

$V_L$  = Low Voltage Level.

\* At this point, when both  $f_R$  and  $f_V$  are in phase, the output is forced to near mid-supply.

NOTE: The  $PD_{out}$  generates error pulses during out-of-lock conditions. When locked in phase and frequency the output is high and the voltage at this pin is determined by the low-pass filter capacitor.

**Figure 9. Phase Detector/Lock Detector Output Waveforms**

## DESIGN CONSIDERATIONS

### PHASE-LOCKED LOOP — LOW-PASS FILTER DESIGN

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NR_1 C}}$$

$$\zeta = \frac{N\omega_n}{2K_\phi K_{VCO}}$$

$$F(s) = \frac{1}{R_1 s C + 1}$$

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC(R_1 + R_2)}}$$

$$\zeta = 0.5 \omega_n \left( R_2 C + \frac{N}{K_\phi K_{VCO}} \right)$$

$$F(s) = \frac{R_2 s C + 1}{(R_1 + R_2) s C + 1}$$

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NCR_1}}$$

$$\zeta = \frac{\omega_n R_2 C}{2}$$

ASSUMING GAIN A IS VERY LARGE, THEN:

$$F(s) = \frac{R_2 s C + 1}{R_1 s C}$$

NOTE: Sometimes  $R_1$  is split into two series resistors, each  $R_1 \div 2$ . A capacitor  $C_C$  is then placed from the midpoint to ground to further filter  $\phi_V$  and  $\phi_R$ . The value of  $C_C$  should be such that the corner frequency of this network does not significantly affect  $\omega_n$ . The  $\phi_R$  and  $\phi_V$  outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp used in the combiner/loop filter.

#### DEFINITIONS:

$N$  = Total Division Ratio in feedback loop

$K_\phi$  (Phase Detector Gain) =  $V_{DD}/4\pi$  for  $PD_{out}$

$K_\phi$  (Phase Detector Gain) =  $V_{DD}/2\pi$  for  $\phi_V$  and  $\phi_R$

$K_{VCO}$  (VCO Gain) =  $\frac{2\pi\Delta f_{VCO}}{\Delta V_{VCO}}$

for a typical design  $\omega_n$  (Natural Frequency)  $\approx \frac{2\pi f_r}{10}$  (at phase detector input).

Damping Factor:  $\zeta \cong 1$

## CRYSTAL OSCILLATOR CONSIDERATIONS

The following options may be considered to provide a reference frequency to Motorola's CMOS frequency synthesizers.

### Use of a Hybrid Crystal Oscillator

Commercially available temperature-compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide very stable reference frequencies. An oscillator capable of sinking and sourcing 50  $\mu$ A at CMOS logic levels may be direct or dc coupled to OSC<sub>in</sub>. In general, the highest frequency capability is obtained utilizing a direct-coupled square wave having a rail-to-rail (V<sub>DD</sub> to V<sub>SS</sub>) voltage swing. If the oscillator does not have CMOS logic levels on the outputs, capacitive or ac coupling to OSC<sub>in</sub> may be used. OSC<sub>out</sub>, an unbuffered output, should be left floating.

For additional information about TCXOs and data clock oscillators, please consult the latest version of the *eem Electronic Engineers Master Catalog*, the *Gold Book*, or similar publications.

### Design an Off-Chip Reference

The user may design an off-chip crystal oscillator using ICs specifically developed for crystal oscillator applications, such as the MC12061 MECL device. The reference signal from the MECL device is ac coupled to OSC<sub>in</sub>. For large amplitude signals (standard CMOS logic levels), dc coupling is used. OSC<sub>out</sub>, an unbuffered output, should be left floating. In general, the highest frequency capability is obtained with a direct-coupled square wave having rail-to-rail voltage swing.

### Use of the On-Chip Oscillator Circuitry

The on-chip amplifier (a digital inverter) along with an appropriate crystal may be used to provide a reference source frequency. A fundamental mode crystal, parallel resonant at the desired operating frequency, should be connected as shown in Figure 10.

\* May be deleted in certain cases. See text.

**Figure 10. Pierce Crystal Oscillator Circuit**

For V<sub>DD</sub> = 5.0 V, the crystal should be specified for a loading capacitance, C<sub>L</sub>, which does not exceed 32 pF for frequencies to approximately 8.0 MHz, 20 pF for frequencies in the area of 8.0 to 15 MHz, and 10 pF for higher frequencies. These are guidelines that provide a reasonable compromise between IC capacitance, drive capability, swamping variations in stray and IC input/output capacitance, and realistic

C<sub>L</sub> values. The shunt load capacitance, C<sub>L</sub>, presented across the crystal can be estimated to be:

$$C_L = \frac{C_{in}C_{out}}{C_{in} + C_{out}} + C_a + C_o + \frac{C_1 \cdot C_2}{C_1 + C_2}$$

where

C<sub>in</sub> = 5 pF (see Figure 11)

C<sub>out</sub> = 6 pF (see Figure 11)

C<sub>a</sub> = 1 pF (see Figure 11)

C<sub>o</sub> = the crystal's holder capacitance (see Figure 12)

C1 and C2 = external capacitors (see Figure 10)

**Figure 11. Parasitic Capacitances of the Amplifier**

NOTE: Values are supplied by crystal manufacturer (parallel resonant crystal).

**Figure 12. Equivalent Crystal Networks**

The oscillator can be "trimmed" on-frequency by making a portion or all of C1 variable. The crystal and associated components must be located as close as possible to the OSC<sub>in</sub> and OSC<sub>out</sub> pins to minimize distortion, stray capacitance, stray inductance, and startup stabilization time. In some cases, stray capacitance should be added to the value for C<sub>in</sub> and C<sub>out</sub>.

Power is dissipated in the effective series resistance of the crystal, R<sub>e</sub>, in Figure 12. The drive level specified by the crystal manufacturer is the maximum stress that a crystal can withstand without damage or excessive shift in frequency. R1 in Figure 10 limits the drive level. The use of R1 may not be necessary in some cases (i.e., R1 = 0  $\Omega$ ).

To verify that the maximum dc supply voltage does not overdrive the crystal, monitor the output frequency as a function of voltage at OSC<sub>out</sub>. (Care should be taken to minimize loading.) The frequency should increase very slightly as the dc supply voltage is increased. An overdriven crystal will decrease in frequency or become unstable with an increase in supply voltage. The operating supply voltage must be reduced or R1 must be increased in value if the overdriven condition exists. The user should note that the oscillator start-up time is proportional to the value of R1.

Through the process of supplying crystals for use with CMOS inverters, many crystal manufacturers have developed expertise in CMOS oscillator design with crystals. Discussions with such manufacturers can prove very helpful (see Table 1).

**DUAL–MODULUS PRESCALING**

**OVERVIEW**

The technique of dual–modulus prescaling is well established as a method of achieving high performance frequency synthesizer operation at high frequencies. Basically, the approach allows relatively low–frequency programmable counters to be used as high–frequency programmable counters with speed capability of several hundred MHz. This is possible without the sacrifice in system resolution and performance that results if a fixed (single–modulus) divider is used for the prescaler.

In dual–modulus prescaling, the lower speed counters must be uniquely configured. Special control logic is necessary to select the divide value P or P + 1 in the prescaler for the required amount of time (see modulus control definition). Motorola’s dual–modulus frequency synthesizers contain this feature and can be used with a variety of dual–modulus prescalers to allow speed, complexity and cost to be tailored to the system requirements. Prescalers having P, P + 1 divide values in the range of ÷ 3/÷ 4 to ÷ 128/÷ 129 can be controlled by most Motorola frequency synthesizers.

Several dual–modulus prescaler approaches suitable for use with the MC145152–2, MC145156–2, or MC145158–2 are:

MC12009	÷ 5/÷ 6	440 MHz
MC12011	÷ 8/÷ 9	500 MHz
MC12013	÷ 10/÷ 11	500 MHz
MC12015	÷ 32/÷ 33	225 MHz
MC12016	÷ 40/÷ 41	225 MHz
MC12017	÷ 64/÷ 65	225 MHz
MC12018	÷ 128/÷ 129	520 MHz
MC12028A	÷ 32/33 or ÷ 64/65	1.1 GHz
MC12052A	÷ 64/65 or ÷ 128/129	1.1 GHz
MC12054A	÷ 64/65 or ÷ 128/129	2.0 GHz

**DESIGN GUIDELINES**

The system total divide value, N<sub>total</sub> (N<sub>T</sub>) will be dictated by the application:

$$N_T = \frac{\text{frequency into the prescaler}}{\text{frequency into the phase detector}} = N \cdot P + A$$

N is the number programmed into the ÷ N counter, A is the number programmed into the ÷ A counter, P and P + 1 are the two selectable divide ratios available in the dual–modulus prescalers. To have a range of N<sub>T</sub> values in sequence, the ÷ A counter is programmed from zero through P – 1 for a particular value N in the ÷ N counter. N is then incremented to N + 1 and the ÷ A is sequenced from 0 through P – 1 again.

There are minimum and maximum values that can be achieved for N<sub>T</sub>. These values are a function of P and the size of the ÷ N and ÷ A counters.

The constraint N ≥ A always applies. If A<sub>max</sub> = P – 1, then N<sub>min</sub> ≥ P – 1. Then N<sub>Tmin</sub> = (P – 1) P + A or (P – 1) P since A is free to assume the value of 0.

$$N_{Tmax} = N_{max} \cdot P + A_{max}$$

To maximize system frequency capability, the dual–modulus prescaler output must go from low to high after each group of P or P + 1 input cycles. The prescaler should divide by P when its modulus control line is high and by P + 1 when its MC is low.

For the maximum frequency into the prescaler (f<sub>VCOmax</sub>), the value used for P must be large enough such that:

- f<sub>VCOmax</sub> divided by P may not exceed the frequency capability of f<sub>in</sub> (input to the ÷ N and ÷ A counters).
- The period of f<sub>VCO</sub> divided by P must be greater than the sum of the times:
  - Propagation delay through the dual–modulus prescaler.
  - Prescaler setup or release time relative to its MC signal.
  - Propagation time from f<sub>in</sub> to the MC output for the frequency synthesizer device.

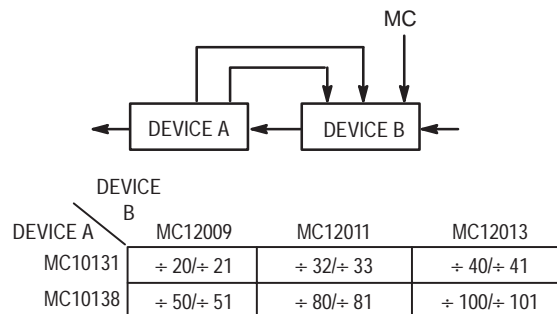

A sometimes useful simplification in the programming code can be achieved by choosing the values for P of 8, 16, 32, or 64. For these cases, the desired value of N<sub>T</sub> results when N<sub>T</sub> in binary is used as the program code to the ÷ N and ÷ A counters treated in the following manner:

- Assume the ÷ A counter contains “a” bits where 2<sup>a</sup> ≥ P.
- Always program all higher order ÷ A counter bits above “a” to 0.

3. Assume the  $\div N$  counter and the  $\div A$  counter (with all the higher order bits above “a” ignored) combined into a single binary counter of  $n + a$  bits in length ( $n$  = number of divider stages in the  $\div N$  counter). The MSB of this “hypothetical” counter is to correspond to the MSB of  $\div N$  and

the LSB is to correspond to the LSB of  $\div A$ . The system divide value,  $N_T$ , now results when the value of  $N_T$  in binary is used to program the “new”  $n + a$  bit counter.

By using the two devices, several dual-modulus values are achievable (shown in Figure 13).

NOTE: MC12009, MC12011, and MC12013 are pin equivalent.  
MC12015, MC12016, and MC12017 are pin equivalent.

**Figure 13. Dual-Modulus Values**

# 60 MHz and 85 MHz Universal Programmable Dual PLL Frequency Synthesizers CMOS

The MC145162 is a dual phase-locked loop (PLL) frequency synthesizer especially designed for CT-1 cordless phone applications worldwide. This frequency synthesizer is also for any product with a frequency operation at 60 MHz or below.

The MC145162-1 is a high frequency derivative of the MC145162, for products with operating frequencies of 85 MHz or below.

The device features fully programmable receive, transmit, reference, and auxiliary reference counters accessed through an MCU serial interface. This feature allows this device to operate in any CT-1 cordless phone application. The device consists of two independent phase detectors for transmit and receive loops. A common reference oscillator, driving two independent reference frequency counters, provides independent reference frequencies for transmit and receive loops. The auxiliary reference counter allows the user to select an additional reference frequency for receive and transmit loops if required.

- Operating Voltage Range: 2.5 to 5.5 V
- Operating Temperature Range: - 40 to + 75°C
- Operating Power Consumption: 3.0 mA @ 2.5 V
- Maximum Operating Frequency:
  - MC145162 — 60 MHz @ 200 mV p-p,  $V_{DD} = 2.5$  V
  - MC145162-1 — 85 MHz @ 250 mV p-p,  $V_{DD} = 2.5$  V
- Three or Four Pins Used for Serial MCU Interface
- Built-In MCU Clock Output with Frequency of Reference Oscillator  $\div 3/\div 4$
- Power Saving Mode Controlled by MCU
- Lock Detect Signal
- On-Chip Reference Oscillator Supports External Crystals to 16.0 MHz
- Reference Frequency Counter Division Range: 16 to 4095
- Auxiliary Reference Frequency Counter Division Range: 16 to 16,383
- Transmit Counter Division Range: 16 to 65,535
- Receive Counter Division Range: 16 to 65,535

### PIN ASSIGNMENT

### BLOCK DIAGRAM

**MAXIMUM RATINGS\*** (Voltages Referenced to  $V_{SS}$ )

Symbol	Rating	Value	Unit
$V_{DD}$	DC Supply Voltage	- 0.5 to + 6.0	V
$V_{in}$	Input Voltage, All Inputs	- 0.5 to $V_{DD} + 0.5$	V
$I_{in}, I_{out}$	DC Current Drain Per Pin	10	mA
$I_{DD}, I_{SS}$	DC Current Drain $V_{DD}$ or $V_{SS}$ Pins	30	mA
$T_{stg}$	Storage Temperature Range	- 65 to + 150	°C

\* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation,  $V_{in}$  and  $V_{out}$  should be constrained to the range  $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{DD}$ .

Unused pins must always be tied to an appropriate logic voltage level (e.g., either  $V_{SS}$  or  $V_{DD}$ ). Unused outputs must be left open.

## PIN DESCRIPTIONS

### INPUT PINS

#### OSC<sub>in</sub> /OSC<sub>out</sub>

##### Reference Oscillator Input/Output (Pins 7, 8)

These pins form a reference oscillator when connected to an external parallel-resonant crystal. Figure 6 shows the relationship of different crystal frequencies and reference frequencies for cordless phone applications in various countries. OSC<sub>in</sub> may also serve as input for an externally generated reference signal which is typically ac coupled.

#### MCUCLK

##### System Clock (Pin 5)

This output pin provides a signal of the crystal frequency (OSC<sub>out</sub>) divided by 3 or 4 that is controlled by a bit in the control register.

This signal can be a clock source for the MCU or other system clocks.

#### AD<sub>in</sub>, D<sub>in</sub>, CLK, ENB

##### Auxiliary Data In, Data In, Clock, Enable (Pins 2, 3, 1, 4)

These four pins provide an MCU serial interface for programming the reference counter, the transmit-channel counter, and the receive-channel counter. They also provide various controls of the PLL including the power saving mode and the programming format.

#### TxPS/f<sub>Tx</sub>, RxPS/f<sub>Rx</sub>

##### Transmit Power Save, Receive Power Save (Pins 13, 11)

For a normal application, these output pins provide the status of the internal power saving mode operation. If the transmit-channels counter circuitry is in power down mode, TxPS/f<sub>Tx</sub> outputs a high state. If the receive-channels counter circuitry is in power down mode, RxPS/f<sub>Rx</sub> is set high. These outputs can be applied for controlling the external power switch for the transmitter and the receiver to save MCU control pins.

In the Tx/Rx channel counter test mode, the TxPS/f<sub>Tx</sub> and RxPS/f<sub>Rx</sub> pins output the divided value of the transmit channel counter (f<sub>Tx</sub>) and the receive channel counter (f<sub>Rx</sub>), respectively. This test mode operation is controlled by the

control register. Details of the counter test mode are in the Tx/Rx Channel Counter Test section of this data sheet.

#### f<sub>in-T</sub>/f<sub>in-R</sub>

##### Transmit/Receive Counter Inputs (Pins 14, 9)

f<sub>in-T</sub> and f<sub>in-R</sub> are inputs to the transmit and the receive counters, respectively. These signals are typically driven from the loop VCO and ac coupled. The minimum input signal level is 200 mV p-p @ 60.0 MHz.

### OUTPUT PINS

#### TxPD<sub>out</sub>/RxPD<sub>out</sub>

##### Transmit/Receive Phase Detector Outputs (Pins 15, 10)

These are three-state outputs of the transmit and receive phase detectors for use as loop error signals (see Figure 7 for phase detector output waveforms). Phase detector gain is V<sub>DD</sub>/4 π volts per radian.

Frequency f<sub>V</sub> > f<sub>R</sub> or f<sub>V</sub> leading: output = negative pulse.

Frequency f<sub>V</sub> < f<sub>R</sub> or f<sub>V</sub> lagging: output = positive pulse.

Frequency f<sub>V</sub> = f<sub>R</sub> and phase coincidence: output = high-impedance state.

NOTE: f<sub>R</sub> is the divided-down reference frequency at the phase detector input and f<sub>V</sub> is the divided-down VCO frequency at the phase detector input.

#### $\overline{\text{LD}}$

##### Lock Detect (Pin 16)

The lock detect signal is associated with the transmit loop. The output at a high level indicates an out-of-lock condition (see Figure 7 for the  $\overline{\text{LD}}$  output waveform).

### POWER SUPPLY

#### V<sub>DD</sub>

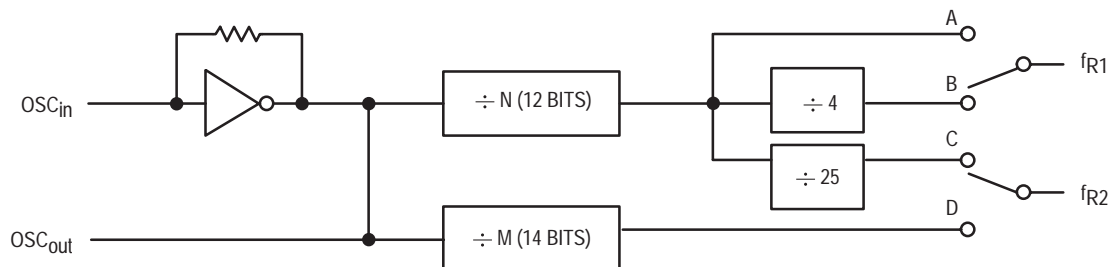

##### Positive Power Supply (Pin 12)

V<sub>DD</sub> is the most positive power supply potential ranging from 2.5 to 5.5 V with respect to V<sub>SS</sub>.

#### V<sub>SS</sub>

##### Negative Power Supply (Pin 6)

V<sub>SS</sub> is the most negative supply potential and is usually connected to ground.

Crystal	÷ N Value	f <sub>R1</sub> B	f <sub>R2</sub> C
11.150 MHz	446	6.25 kHz	1.0 kHz
11.150 MHz	223	12.5 kHz	
10.240 MHz	512	5.0 kHz	
12.000 MHz	600	5.0 kHz	

Figure 6. Reference Frequencies for Cordless Phone Applications of Various Countries

$V_H$  = High voltage level.

$V_L$  = Low voltage level.

\*At this point, when both  $f_R$  and  $f_V$  are in phase, the output is forced to near mid supply.

NOTE: The TxPD<sub>out</sub> and RxPD<sub>out</sub> generate error pulses during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low-pass filter capacitor.

**Figure 7. Phase Detector/Lock Detector Output Waveforms**

## MCU PROGRAMMING SCHEME

The MCU programming scheme is defined in two formats controlled by the ENB input. If the enable signal is high during the serial data transfer, control register/reference frequency programming is selected. If the ENB is low, programming of the transmit and receive counters is selected. During programming of the transmit and receive counters, both AD<sub>IN</sub> and D<sub>IN</sub> pins can input the data to the transmit and receive counters. Both counters' data is clocked into the PLL internal shift register at the leading edge of the CLK signal. It is not necessary to reprogram the reference frequency counter/control register when using the enable signal to program the transmit/receive channels.

In programming the control register/reference frequency scheme, the most significant bit (MSB) of the programming word identifies whether the input data is the control word or the reference frequency data word. If the MSB is 1, the input data is the control word (Figure 8). Also see Figure 8 and Table 1 for control register and bit function. If the MSB is 0, the input data is the reference frequency (Figure 9).

The reference frequency data word is a 32-bit word containing the 12-bit reference frequency data, the 14-bit auxiliary reference frequency counter information, the reference frequency selection plus, the auxiliary reference frequency counter enable bit (Figure 9).

If the AUX REF ENB bit is high, the 14-bit auxiliary reference frequency counter provides an additional phase reference frequency output for the loops. If AUX REF ENB bit is low, the auxiliary reference frequency counter is forced into

power-down mode for current saving. (Other power down modes are also provided through the control register per Table 2 and Figure 8.) At the falling edge of the ENB signal, the data is stored in the registers.

There are two interfacing schemes for the universal channel mode: the three-pin and the four-pin interfacing schemes. The three-pin interfacing scheme is suited for use with the MCU SPI (serial peripheral interface) (Figure 10), while the four-pin interfacing scheme is commonly used for general I/O port connection (Figure 11).

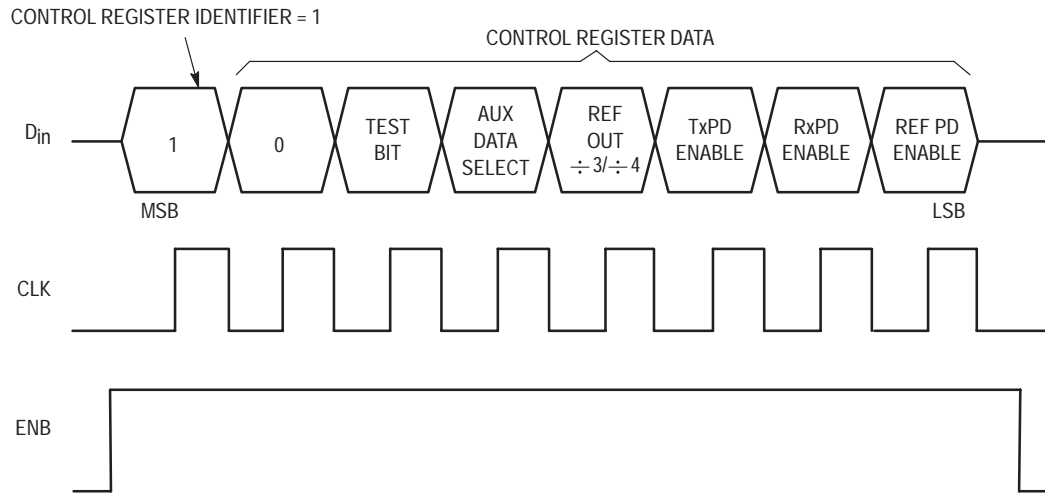

For the three-pin interfacing scheme, the auxiliary data select bit is set to 0. All 32 bits of data, which define both the 16-bit transmit counter and the 16-bit receive counter, latch into the PLL internal register through the data in pins at the leading edge of CLK. See Figures 12 and 13.

For the four-pin interfacing scheme, the auxiliary data select bit is set to 1. In this scheme, the 16-bit transmit counter's data enters into the AD<sub>IN</sub> pin at the same time as the 16-bit receive counter's data enters into the D<sub>IN</sub> pin. This simultaneous entry of the transmit and receive counters causes the programming period of the four-pin scheme to be half that of the three-pin scheme (see Figures 14 and 15).

While programming Tx/Rx Channel Counter, the ENB pin must be pulsed to provide falling edge to latch the shifted data after the rising edge of the last clock. Maximum data transfer rate is 500 kbps.

### NOTE

10 ms should be allowed for initial start-up time for the oscillator to allow all registers to clear and enable programming of new register values.

NOTE: ENB must be high during the serial transfer.

**Figure 8. Programming Format of the Control Register**

**Table 1. Control Register Function Bits Description**

Test Bit	Set to 1 for Tx/Rx channel counter test mode Set to 0 for normal application
Aux Data Select	Set to 1 for both AD <sub>in</sub> and D <sub>in</sub> pins inputting the transmit 16–bits data and receive 16–bits data respectively. Set to 0 for normal application interfacing with MCU serial peripheral interface. Does not use AD <sub>in</sub> pin; tie AD <sub>in</sub> to V <sub>SS</sub> .
REF <sub>out</sub> ÷ 3/÷ 4	If set to 1, REF <sub>out</sub> output frequency is equal to OSC <sub>out</sub> ÷ 3. If set to 0, REF <sub>out</sub> output is OSC <sub>out</sub> ÷ 4.
TxPD Enable	If set to 1, the transmit counter, transmit phase detector, and the associated circuitry is in power–down mode. Tx PS/f <sub>TX</sub> is set “High”.
RxPD Enable	If set to 1, the receive counter, receive phase detector, and the associated circuitry is in power–down mode. Rx PS/f <sub>RX</sub> is set “High”.
Ref PD Enable	If set to 1, both 12–bit and 14–bit reference frequency counters are in power–down mode.

**Table 3. Global CT-1 Reference Frequency Setting vs Channel Frequencies**

Country	Channels Frequency	$f_{R1}$	$f_{R2}$
U.S.A.	46/49 MHz (10, 15, 25 Channels)	5.0 kHz	—
France	26/41 MHz	6.25 kHz/12.5 kHz	—
Spain	31/41 MHz	5.0 kHz	—
Australia	30/39 MHz	5.0 kHz	—
U.K.	1.7/47 MHz	6.25 kHz	1.0 kHz
New Zealand	1.7/34/40 MHz	6.25 kHz	1.0 kHz

### REFERENCE FREQUENCY SELECTION AND PROGRAMMING

Figure 16 shows the bit function of the reference frequency programming word. The user can either select the “fixed” reference frequency for all channels accordingly or provide a specific reference frequency for a particular channel by using two reference frequency counters (e.g., for an application in France, the base set transmit channel common fixed reference frequency is 6.25 kHz or 12.5 kHz). (See Table 3 and Figure 6 for reference frequencies for various countries.) However, transmit channels 6, 8, and 14 can be set to 25 kHz, and channel 8 reference frequency can be set to 50 kHz. But this reference frequency may not be applied to the receiving side; therefore, the receiving side reference frequency must be generated by another reference frequency counter. The higher the reference frequency, the better the phase noise performance and faster the lock time, but the PLL consumes more current if both reference frequency counters are in operation.

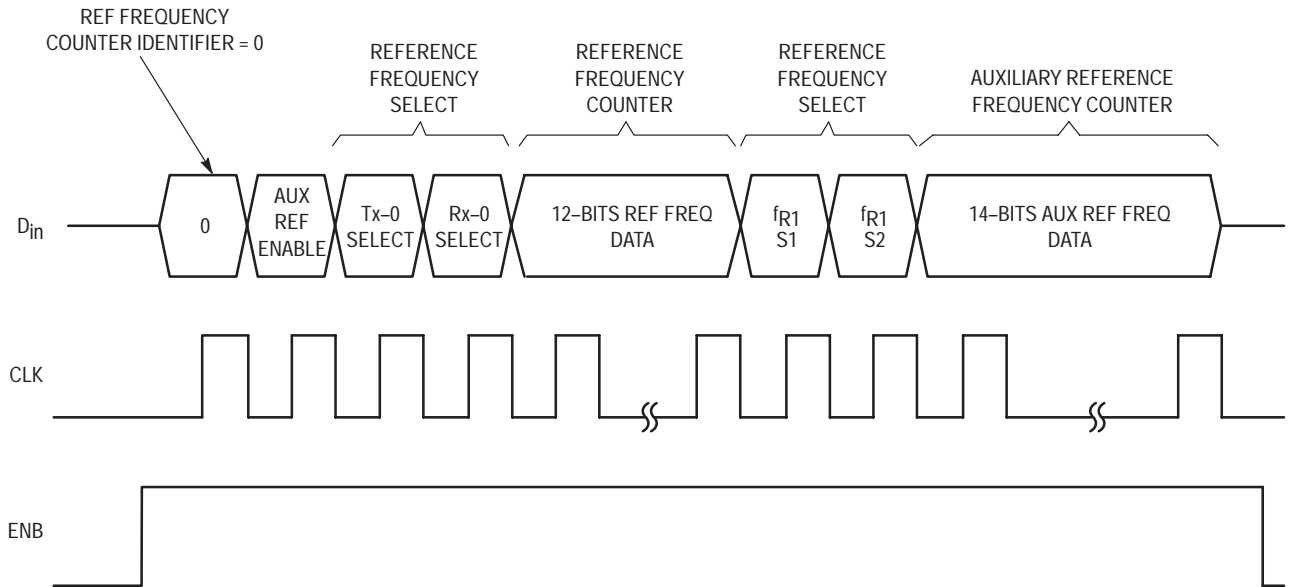

In general, the 12-bit reference frequency counter plus the  $\div 4$  and  $\div 25$  module can offer all the reference frequencies

for global CT-1 transmit and receive channel requirements. Users can select their own reference frequency by introducing the additional 14-bit auxiliary reference frequency counter.

Again, the 14-bit auxiliary reference frequency counter can be shut down by the auxiliary reference enable bit in the reference counter programming word by setting the bit to 0. At this state, the  $f_{R2}$  is automatically connected to point C (the  $\div 25$  block output), and  $f_{R1}$  can be connected to point A or B by setting the  $f_{R1-S1}$  and  $f_{R1-S2}$  bits in the reference counter program word. The 14-bit auxiliary reference frequency counter data will be in “Don’t Care” state.

If the 14-bit auxiliary reference frequency counter is enabled (auxiliary reference enable = 1), then  $f_{R2}$  is automatically connected to point D (14-bit counter output), and  $f_{R1}$  can be selected to connect to point A, B, or C, depending on the bit setting of  $f_{R1-S1}$  and  $f_{R1-S2}$ .

Table 4 and Figure 16 describe the functions of the auxiliary reference enable bit and the  $f_{R1-S1}$  and  $f_{R1-S2}$  bits selection.

NOTE: ENB must be high during the serial transfer.

Figure 16. Reference Frequency Counter/Selection Programming Mode

N/A = Not Applicable

## POWER SAVING OPERATION

This PLL has a programmable power-saving scheme. The transmit and receive counters and the reference frequency counter can be powered down individually by setting the TxPD enable, RxPD enable, and Ref PD enable bits of the control register. The functions of the power down control bits are explained in Table 2 and the programming format is in Figure 8.

The output pins TxPS/f<sub>Tx</sub> and RxPS/f<sub>Rx</sub> output the status of the internal power saving setting. If the bit TxPD enable is set "high" (transmit counter is set to power-down mode), then the TxPS/f<sub>Tx</sub> pin will also output a "high" state. This TxPS/f<sub>Tx</sub> output can control an external power switch to switch off the transmitter, as shown in Figure 17. This scheme can be applied to the RxPS/f<sub>Rx</sub> output to control the receiver power saving operation as required.

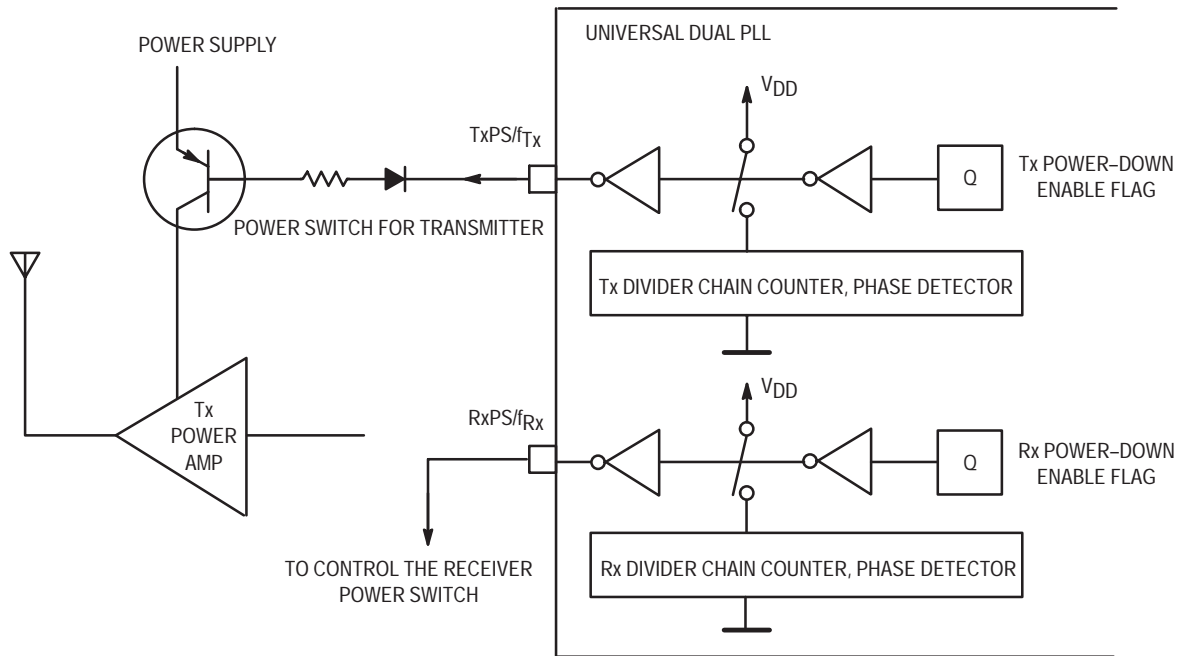

Figure 17. TxPS/f<sub>Tx</sub> and RxPS/f<sub>Rx</sub> Outputs to Control Power Switches of the Transmitter and the Receiver

## Tx/Rx CHANNEL COUNTER TEST

In normal applications, the TxPS/f<sub>Tx</sub> and the RxPS/f<sub>Rx</sub> output pins indicate the power saving mode status. However, the user can examine the Tx and Rx channel counter outputs by setting the Test bit in the control register to 1. The final

value of the transmit-channel counter and the receive-channel counter multiplex out to TxPS/f<sub>Tx</sub> and RxPS/f<sub>Rx</sub> respectively. The user can verify the divided-down output waveform associated with the RF input level in the PLL circuitry implementation (Figure 18).

Figure 18. RF Buffer Sensitivity

# PLL Frequency Synthesizer with Serial Interface

The new MC145170-2 is pin-for-pin compatible with the MC145170-1. A comparison of the two parts is shown in the table below. The MC145170-2 is recommended for new designs and has a more robust power-on reset (POR) circuit that is more responsive to momentary power supply interruptions. The two devices are actually the same chip with mask options for the POR circuit. The more robust POR circuit draws approximately 20  $\mu$ A additional supply current. Note that the maximum specification of 100  $\mu$ A quiescent supply current has not changed.

The MC145170-2 is a single-chip synthesizer capable of direct usage in the MF, HF, and VHF bands. A special architecture makes this PLL easy to program. Either a bit- or byte-oriented format may be used. Due to the patented BitGrabber™ registers, no address/steering bits are required for random access of the three registers. Thus, tuning can be accomplished via a 2-byte serial transfer to the 16-bit N register.

The device features fully programmable R and N counters, an amplifier at the  $f_{in}$  pin, on-chip support of an external crystal, a programmable reference output, and both single- and double-ended phase detectors with linear transfer functions (no dead zones). A configuration (C) register allows the part to be configured to meet various applications. A patented feature allows the C register to shut off unused outputs, thereby minimizing noise and interference.

In order to reduce lock times and prevent erroneous data from being loaded into the counters, a patented jam-load feature is included. Whenever a new divide ratio is loaded into the N register, both the N and R counters are jam-loaded with their respective values and begin counting down together. The phase detectors are also initialized during the jam load.

- Operating Voltage Range: 2.7 to 5.5 V
- Maximum Operating Frequency:
  - 185 MHz @  $V_{in} = 500$  mVpp, 4.5 V Minimum Supply
  - 100 MHz @  $V_{in} = 500$  mVpp, 3.0 V Minimum Supply
- Operating Supply Current:
  - 0.6 mA @ 3.0 V, 30 MHz
  - 1.5 mA @ 3.0 V, 100 MHz
  - 3.0 mA @ 5.0 V, 50 MHz
  - 5.8 mA @ 5.0 V, 185 MHz
- Operating Temperature Range: -40 to 85°C
- R Counter Division Range: 1 and 5 to 32,767
- N Counter Division Range: 40 to 65,535
- Direct Interface to Motorola SPI Serial Data Port
- See Application Notes AN1207/D and AN1671/D
- See web site *mot-sps.com* for MC145170 control software. Select in order, Products, Wireless Semiconductor, Download, then PLL Demo Software. Choose PLLGEN.EXE.

### MAXIMUM RATINGS (Voltages Referenced to $V_{SS}$ )

Parameter	Symbol	Value	Unit
DC Supply Voltage	$V_{DD}$	-0.5 to 5.5	V
DC Input Voltage	$V_{in}$	-0.5 to $V_{DD} + 0.5$	V
DC Output Voltage	$V_{out}$	-0.5 to $V_{DD} + 0.5$	V
DC Input Current, per Pin	$I_{in}$	$\pm 10$	mA
DC Output Current, per Pin	$I_{out}$	$\pm 20$	mA
DC Supply Current, $V_{DD}$ and $V_{SS}$ Pins	$I_{DD}$	$\pm 30$	mA
Power Dissipation, per Package	$P_D$	300	mW
Storage Temperature	$T_{stg}$	-65 to 150	$^{\circ}\text{C}$
Lead Temperature, 1 mm from Case for 10 seconds	$T_L$	260	$^{\circ}\text{C}$

- NOTES:** 1. Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.  
2. ESD data available upon request.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation,  $V_{in}$  and  $V_{out}$  should be constrained to the range  $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{DD}$ .

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either  $V_{SS}$  or  $V_{DD}$ ). Unused outputs must be left open.

## MC145170-2

### ELECTRICAL CHARACTERISTICS (Voltages Referenced to $V_{SS}$ , $T_A = -40$ to $85^\circ\text{C}$ )

Parameter	Test Condition	Symbol	$V_{DD}$ V	Guaranteed Limit	Unit
Power Supply Voltage Range		$V_{DD}$	–	2.7 to 5.5	V
Maximum Low-Level Input Voltage [Note 1] ( $D_{in}$ , CLK, $\overline{ENB}$ , $f_{in}$ )	dc Coupling to $f_{in}$	$V_{IL}$	2.7 4.5 5.5	0.54 1.35 1.65	V
Minimum High-Level Input Voltage [Note 1] ( $D_{in}$ , CLK, $\overline{ENB}$ , $f_{in}$ )	dc Coupling to $f_{in}$	$V_{IH}$	2.7 4.5 5.5	2.16 3.15 3.85	V
Minimum Hysteresis Voltage (CLK, $\overline{ENB}$ )		$V_{Hys}$	2.7 5.5	0.15 0.20	V
Maximum Low-Level Output Voltage (Any Output)	$I_{out} = 20 \mu\text{A}$	$V_{OL}$	2.7 5.5	0.1 0.1	V
Minimum High-Level Output Voltage (Any Output)	$I_{out} = -20 \mu\text{A}$	$V_{OH}$	2.7 5.5	2.6 5.4	V
Minimum Low-Level Output Current ( $PD_{out}$ , $REF_{out}$ , $f_R$ , $f_V$ , LD, $\phi_R$ , $\phi_V$ )	$V_{out} = 0.3 \text{ V}$ $V_{out} = 0.4 \text{ V}$ $V_{out} = 0.5 \text{ V}$	$I_{OL}$	2.7 4.5 5.5	0.12 0.36 0.36	mA
Minimum High-Level Output Current ( $PD_{out}$ , $REF_{out}$ , $f_R$ , $f_V$ , LD, $\phi_R$ , $\phi_V$ )	$V_{out} = 2.4 \text{ V}$ $V_{out} = 4.1 \text{ V}$ $V_{out} = 5.0 \text{ V}$	$I_{OH}$	2.7 4.5 5.5	-0.12 -0.36 -0.36	mA
Minimum Low-Level Output Current ( $D_{out}$ )	$V_{out} = 0.4 \text{ V}$	$I_{OL}$	4.5	1.6	mA
Minimum High-Level Output Current ( $D_{out}$ )	$V_{out} = 4.1 \text{ V}$	$I_{OH}$	4.5	-1.6	mA
Maximum Input Leakage Current ( $D_{in}$ , CLK, $\overline{ENB}$ , $OSC_{in}$ )	$V_{in} = V_{DD}$ or $V_{SS}$	$I_{in}$	5.5	$\pm 1.0$	$\mu\text{A}$
Maximum Input Current ( $f_{in}$ )	$V_{in} = V_{DD}$ or $V_{SS}$	$I_{in}$	5.5	$\pm 150$	$\mu\text{A}$
Maximum Output Leakage Current ( $PD_{out}$ )  ( $D_{out}$ )	$V_{in} = V_{DD}$ or $V_{SS}$ , Output in High-Impedance State	$I_{OZ}$	5.5  5.5	$\pm 100$  $\pm 5.0$	nA  $\mu\text{A}$
Maximum Quiescent Supply Current	$V_{in} = V_{DD}$ or $V_{SS}$ ; Outputs Open; Excluding $f_{in}$ Amp Input Current Component	$I_{DD}$	5.5	100	$\mu\text{A}$
Maximum Operating Supply Current	$f_{in} = 500 \text{ mVpp}$ ; $OSC_{in} = 1.0 \text{ MHz @ } 1.0 \text{ Vpp}$ ; LD, $f_R$ , $f_V$ , $REF_{out} = \text{Inactive and No Connect}$ ; $OSC_{out}$ , $\phi_V$ , $\phi_R$ , $PD_{out} = \text{No Connect}$ ; $D_{in}$ , $\overline{ENB}$ , CLK = $V_{DD}$ or $V_{SS}$	$I_{dd}$	–	[Note 2]	mA

**NOTES:** 1. When dc coupling to the  $OSC_{in}$  pin is used, the pin must be driven rail-to-rail. In this case,  $OSC_{out}$  should be floated.

2. The nominal values at 3.0 V are 0.6 mA @ 30 MHz, and 1.5 mA @ 100 MHz. The nominal values at 5.0 V are 3.0 mA @ 50 MHz, and 5.8 mA @ 185 MHz. These are not guaranteed limits.

## PIN DESCRIPTIONS

### DIGITAL INTERFACE PINS

#### D<sub>in</sub>

##### Serial Data Input (Pin 5)

The bit stream begins with the most significant bit (MSB) and is shifted in on the low-to-high transition of CLK. The bit pattern is 1 byte (8 bits) long to access the C or configuration register, 2 bytes (16 bits) to access the N register, or 3 bytes (24 bits) to access the R register. Additionally, the R register can be accessed with a 15-bit transfer (see Table 1). An optional pattern which resets the device is shown in Figure 13. The values in the C, N, and R registers do not change during shifting because the transfer of data to the registers is controlled by  $\overline{\text{ENB}}$ .

The bit stream needs neither address nor steering bits due to the innovative BitGrabber registers. Therefore, all bits in the stream are available to be data for the three registers. Random access of any register is provided (i.e., the registers may be accessed in any sequence). Data is retained in the registers over a supply range of 2.7 to 5.5 V. The formats are shown in Figures 13, 14, 15, and 16.

D<sub>in</sub> typically switches near 50% of V<sub>DD</sub> to maximize noise immunity. This input can be directly interfaced to CMOS devices with outputs guaranteed to switch near rail-to-rail. When interfacing to NMOS or TTL devices, either a level shifter (MC74HC14A, MC14504B) or pull-up resistor of 1 to 10 k $\Omega$  must be used. Parameters to consider when sizing the resistor are worst-case I<sub>OL</sub> of the driving device, maximum tolerable power consumption, and maximum data rate.

**Table 1. Register Access**  
(MSBs are shifted in first, C0, N0, and R0 are the LSBs)

Number of Clocks	Accessed Register	Bit Nomenclature
9 to 13	See Figure 13	(Reset)
8	C Register	C7, C6, C5, . . . , C0
16	N Register	N15, N14, N13, . . . , N0
15 or 24	R Register	R14, R13, R12, . . . , R0
Other Values $\leq$ 32	None	
Values > 32	See Figures 24 — 31	

#### CLK

##### Serial Data Clock Input (Pin 7)

Low-to-high transitions on Clock shift bits available at D<sub>in</sub>, while high-to-low transitions shift bits from D<sub>out</sub>. The chip's 16–1/2-stage shift register is static, allowing clock rates down to dc in a continuous or intermittent mode.

Four to eight clock cycles followed by five clock cycles are needed to reset the device; this is optional. Eight clock cycles are required to access the C register. Sixteen clock cycles are needed for the N register. Either 15 or 24 cycles can be used to access the R register (see Table 1 and Figures 13, 14, 15, and 16). For cascaded devices, see Figures 24 to 31.

CLK typically switches near 50% of V<sub>DD</sub> and has a Schmitt-triggered input buffer. Slow CLK rise and fall times are allowed. See the last paragraph of D<sub>in</sub> for more information.

#### NOTE

To guarantee proper operation of the power-on reset (POR) circuit, the CLK pin must be held at the potential of either the V<sub>SS</sub> or V<sub>DD</sub> pin during power up. That is, the CLK input should not be floated or toggled while the V<sub>DD</sub> pin is ramping from 0 to at least 2.7 V. If control of the CLK pin is not practical during power up, the initialization sequence shown in Figure 13 must be used.

#### $\overline{\text{ENB}}$

##### Active-Low Enable Input (Pin 6)

This pin is used to activate the serial interface to allow the transfer of data to/from the device. When  $\overline{\text{ENB}}$  is in an inactive high state, shifting is inhibited, D<sub>out</sub> is forced to the high-impedance state, and the port is held in the initialized state. To transfer data to the device,  $\overline{\text{ENB}}$  (which must start inactive high) is taken low, a serial transfer is made via D<sub>in</sub> and CLK, and  $\overline{\text{ENB}}$  is taken back high. The low-to-high transition on  $\overline{\text{ENB}}$  transfers data to the C, N, or R register depending on the data stream length per Table 1.

#### NOTE

Transitions on  $\overline{\text{ENB}}$  must not be attempted while CLK is high. This puts the device out of synchronization with the microcontroller. Resynchronization occurs when  $\overline{\text{ENB}}$  is high and CLK is low.

This input is also Schmitt-triggered and switches near 50% of V<sub>DD</sub>, thereby minimizing the chance of loading erroneous data into the registers. See the last paragraph of D<sub>in</sub> for more information.

#### D<sub>out</sub>

##### Three-State Serial Data Output (Pin 8)

Data is transferred out of the 16–1/2-stage shift register through D<sub>out</sub> on the high-to-low transition of CLK. This output is a No Connect, unless used in one of the manners discussed below.

D<sub>out</sub> could be fed back to an MCU/MPU to perform a wrap-around test of serial data. This could be part of a system check conducted at power up to test the integrity of the system's processor, PC board traces, solder joints, etc.

The pin could be monitored at an in-line QA test during board manufacturing.

Finally, D<sub>out</sub> facilitates troubleshooting a system and permits cascading devices.

### REFERENCE PINS

#### OSC<sub>in</sub>/OSC<sub>out</sub>

##### Reference Oscillator Input/Output (Pins 1, 2)

These pins form a reference oscillator when connected to terminals of an external parallel-resonant crystal. Frequency-setting capacitors of appropriate values as recommended by the crystal supplier are connected from each pin to ground (up to a maximum of 30 pF each, including stray capacitance). An external feedback resistor of 1.0 to 5.0 M $\Omega$  is connected directly across the pins to ensure linear operation of the amplifier. The required connections for the components are shown in Figure 9.

If desired, an external clock source can be ac coupled to OSC<sub>in</sub>. A 0.01  $\mu$ F coupling capacitor is used for measurement purposes and is the minimum size

recommended for applications. An external feedback resistor of approximately 5 M $\Omega$  is required across the OSC<sub>in</sub> and OSC<sub>out</sub> pins in the ac-coupled case (see Figure 8a or alternate circuit 8b). OSC<sub>out</sub> is an internal node on the device and should not be used to drive any loads (i.e., OSC<sub>out</sub> is unbuffered). However, the buffered REF<sub>out</sub> is available to drive external loads.

The external signal level must be at least 1 V<sub>p-p</sub>; the maximum frequencies are given in the **Loop Specifications** table. These maximum frequencies apply for R Counter divide ratios as indicated in the table. For very small ratios, the maximum frequency is limited to the divide ratio times 2 MHz. (Reason: the phase/frequency detectors are limited to a maximum input frequency of 2 MHz.)

If an external source is available which swings virtually rail-to-rail (V<sub>DD</sub> to V<sub>SS</sub>), then dc coupling can be used. In the dc-coupled case, no external feedback resistor is needed. OSC<sub>out</sub> must be a No Connect to avoid loading an internal node on the device, as noted above. *For frequencies below 1 MHz, dc coupling must be used.* The R counter is a static counter and may be operated down to dc. However, wave shaping by a CMOS buffer may be required to ensure fast rise and fall times into the OSC<sub>in</sub> pin. See Figure 22.

Each rising edge on the OSC<sub>in</sub> pin causes the R counter to decrement by one.

#### REF<sub>out</sub>

##### Reference Frequency Output (Pin 3)

This output is the buffered output of the crystal-generated reference frequency or externally provided reference source. This output may be enabled, disabled, or scaled via bits in the C register (see Figure 14).

REF<sub>out</sub> can be used to drive a microprocessor clock input, thereby saving a crystal. Upon power up, the on-chip power-on-initialize circuit forces REF<sub>out</sub> to the OSC<sub>in</sub> divided-by-8 mode.

REF<sub>out</sub> is capable of operation to 10 MHz; see the **Loop Specifications** table. Therefore, divide values for the reference divider are restricted to two or higher for OSC<sub>in</sub> frequencies above 10 MHz.

If unused, the pin should be floated and should be disabled via the C register to minimize dynamic power consumption and electromagnetic interference (EMI).

#### COUNTER OUTPUT PINS

##### f<sub>R</sub>

##### R Counter Output (Pin 9)

This signal is the buffered output of the 15-stage R counter. f<sub>R</sub> can be enabled or disabled via the C register (patented). The output is disabled (static low logic level) upon power up. If unused, the output should be left disabled and unconnected to minimize interference with external circuitry.

The f<sub>R</sub> signal can be used to verify the R counter's divide ratio. This ratio extends from 5 to 32,767 and is determined by the binary value loaded into the R register. Also, direct access to the phase detector via the OSC<sub>in</sub> pin is allowed by choosing a divide value of 1 (see Figure 15). The maximum frequency which the phase detectors operate is 2 MHz. Therefore, the frequency of f<sub>R</sub> must not exceed 2 MHz.

When activated, the f<sub>R</sub> signal appears as normally low and pulses high. The pulse width is 4.5 cycles of the OSC<sub>in</sub> pin signal, except when a divide ratio of 1 is selected. When 1 is

selected, the OSC<sub>in</sub> signal is buffered and appears at the f<sub>R</sub> pin.

##### f<sub>V</sub>

##### N Counter Output (Pin 10)

This signal is the buffered output of the 16-stage N counter. f<sub>V</sub> can be enabled or disabled via the C register (patented). The output is disabled (static low logic level) upon power up. If unused, the output should be left disabled and unconnected to minimize interference with external circuitry.

The f<sub>V</sub> signal can be used to verify the N counter's divide ratio. This ratio extends from 40 to 65,535 and is determined by the binary value loaded into the N register. The maximum frequency which the phase detectors operate is 2 MHz. Therefore, the frequency of f<sub>V</sub> must not exceed 2 MHz.

When activated, the f<sub>V</sub> signal appears as normally low and pulses high.

#### LOOP PINS

##### f<sub>in</sub>

##### Frequency Input (Pin 4)

This pin is a frequency input from the VCO. This pin feeds the on-chip amplifier which drives the N counter. This signal is normally sourced from an external voltage-controlled oscillator (VCO), and is ac-coupled into f<sub>in</sub>. A 100 pF coupling capacitor is used for measurement purposes and is the minimum size recommended for applications (see Figure 7). The frequency capability of this input is dependent on the supply voltage as listed in the **Loop Specifications** table. For small divide ratios, the maximum frequency is limited to the divide ratio times 2 MHz. (Reason: the phase/frequency detectors are limited to a maximum frequency of 2 MHz.)

For signals which swing from at least the V<sub>IL</sub> to V<sub>IH</sub> levels listed in the **Electrical Characteristics** table, dc coupling may be used. Also, for low frequency signals (less than the minimum frequencies shown in the **Loop Specifications** table), dc coupling is a requirement. The N counter is a static counter and may be operated down to dc. However, wave shaping by a CMOS buffer may be required to ensure fast rise and fall times into the f<sub>in</sub> pin. See Figure 22.

Each rising edge on the f<sub>in</sub> pin causes the N counter to decrement by 1.

##### PD<sub>out</sub>

##### Single-Ended Phase/Frequency Detector Output (Pin 13)

This is a three-state output for use as a loop error signal when combined with an external low-pass filter. Through use of a Motorola patented technique, the detector's dead zone has been eliminated. Therefore, the phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 17.

POL bit (C7) in the C register = low (see Figure 14)

Frequency of f<sub>V</sub> > f<sub>R</sub> or Phase of f<sub>V</sub> Leading f<sub>R</sub>: negative pulses from high impedance

Frequency of f<sub>V</sub> < f<sub>R</sub> or Phase of f<sub>V</sub> Lagging f<sub>R</sub>: positive pulses from high impedance

Frequency and Phase of f<sub>V</sub> = f<sub>R</sub>: essentially high-impedance state; voltage at pin determined by loop filter

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ : positive pulses from high impedance

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ : negative pulses from high impedance

Frequency and Phase of  $f_V = f_R$ : essentially high-impedance state; voltage at pin determined by loop filter

This output can be enabled, disabled, and inverted via the C register. If desired,  $PD_{out}$  can be forced to the high-impedance state by utilization of the disable feature in the C register (patented).

$\phi_R$  and  $\phi_V$

**Double-Ended Phase/Frequency Detector Outputs (Pins 14, 15)**

These outputs can be combined externally to generate a loop error signal. Through use of a Motorola patented technique, the detector's dead zone has been eliminated. Therefore, the phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 17.

POL bit (C7) in the C register = low (see Figure 14)

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_V =$  negative pulses,  $\phi_R =$  essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_V =$  essentially high,  $\phi_R =$  negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_R =$  negative pulses,  $\phi_V =$  essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_R =$  essentially high,  $\phi_V =$  negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

These outputs can be enabled, disabled, and interchanged via the C register (patented).

**LD**

**Lock Detector Output (Pin 11)**

This output is essentially at a high level with narrow low-going pulses when the loop is locked ( $f_R$  and  $f_V$  of the same phase and frequency). The output pulses low when  $f_V$  and  $f_R$  are out of phase or different frequencies (see Figure 17).

This output can be enabled and disabled via the C register (patented). Upon power up, on-chip initialization circuitry disables LD to a static low logic level to prevent a false "lock" signal. If unused, LD should be disabled and left open.

**POWER SUPPLY**

**VDD**

**Most Positive Supply Potential (Pin 16)**

This pin may range from 2.7 to 5.5 V with respect to  $V_{SS}$ .

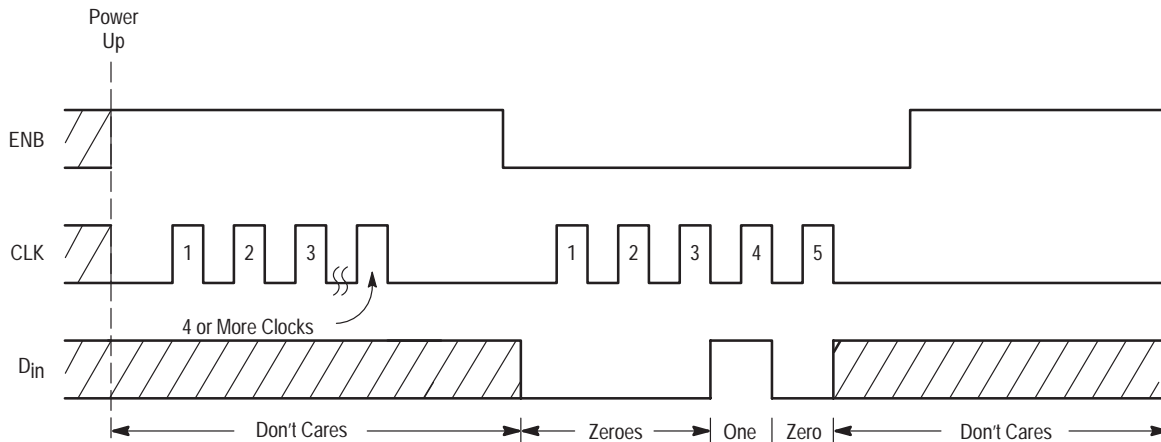

For optimum performance,  $V_{DD}$  should be bypassed to  $V_{SS}$  using low-inductance capacitor(s) mounted very close to the device. Lead lengths on the capacitor(s) should be minimized. (The very fast switching speed of the device causes current spikes on the power leads.)

**VSS**

**Most Negative Supply Potential (Pin 12)**

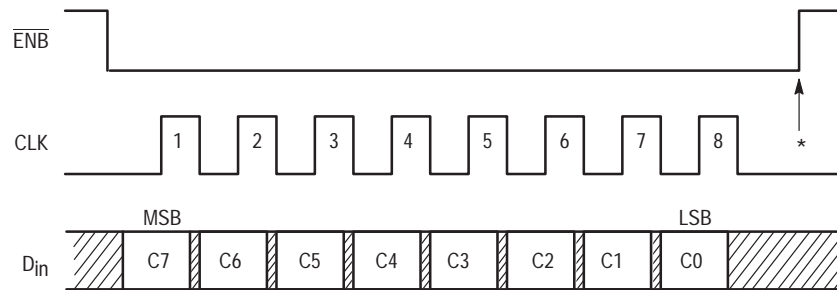

This pin is usually ground. For measurement purposes, the  $V_{SS}$  pin is tied to a ground plane.

Figure 13. Reset Sequence

**NOTE:** This initialization sequence is usually not necessary because the on-chip power-on reset circuit performs the initialization function. However, this initialization sequence must be used immediately after power up if control of the CLK pin is not possible. That is, if CLK (Pin 7) toggles or floats upon power up, use the above sequence to reset the device. Also, use this sequence if power is momentarily interrupted such that the supply voltage to the device is reduced to below 2.7 V, but not down to at least 1 V (for example, the supply drops down to 2 V). This is necessary because the on-chip power-on reset is only activated when the supply ramps up from a voltage below approximately 1.0 V.

Figure 14. C Register Access and Format (8 Clock Cycles are Used)

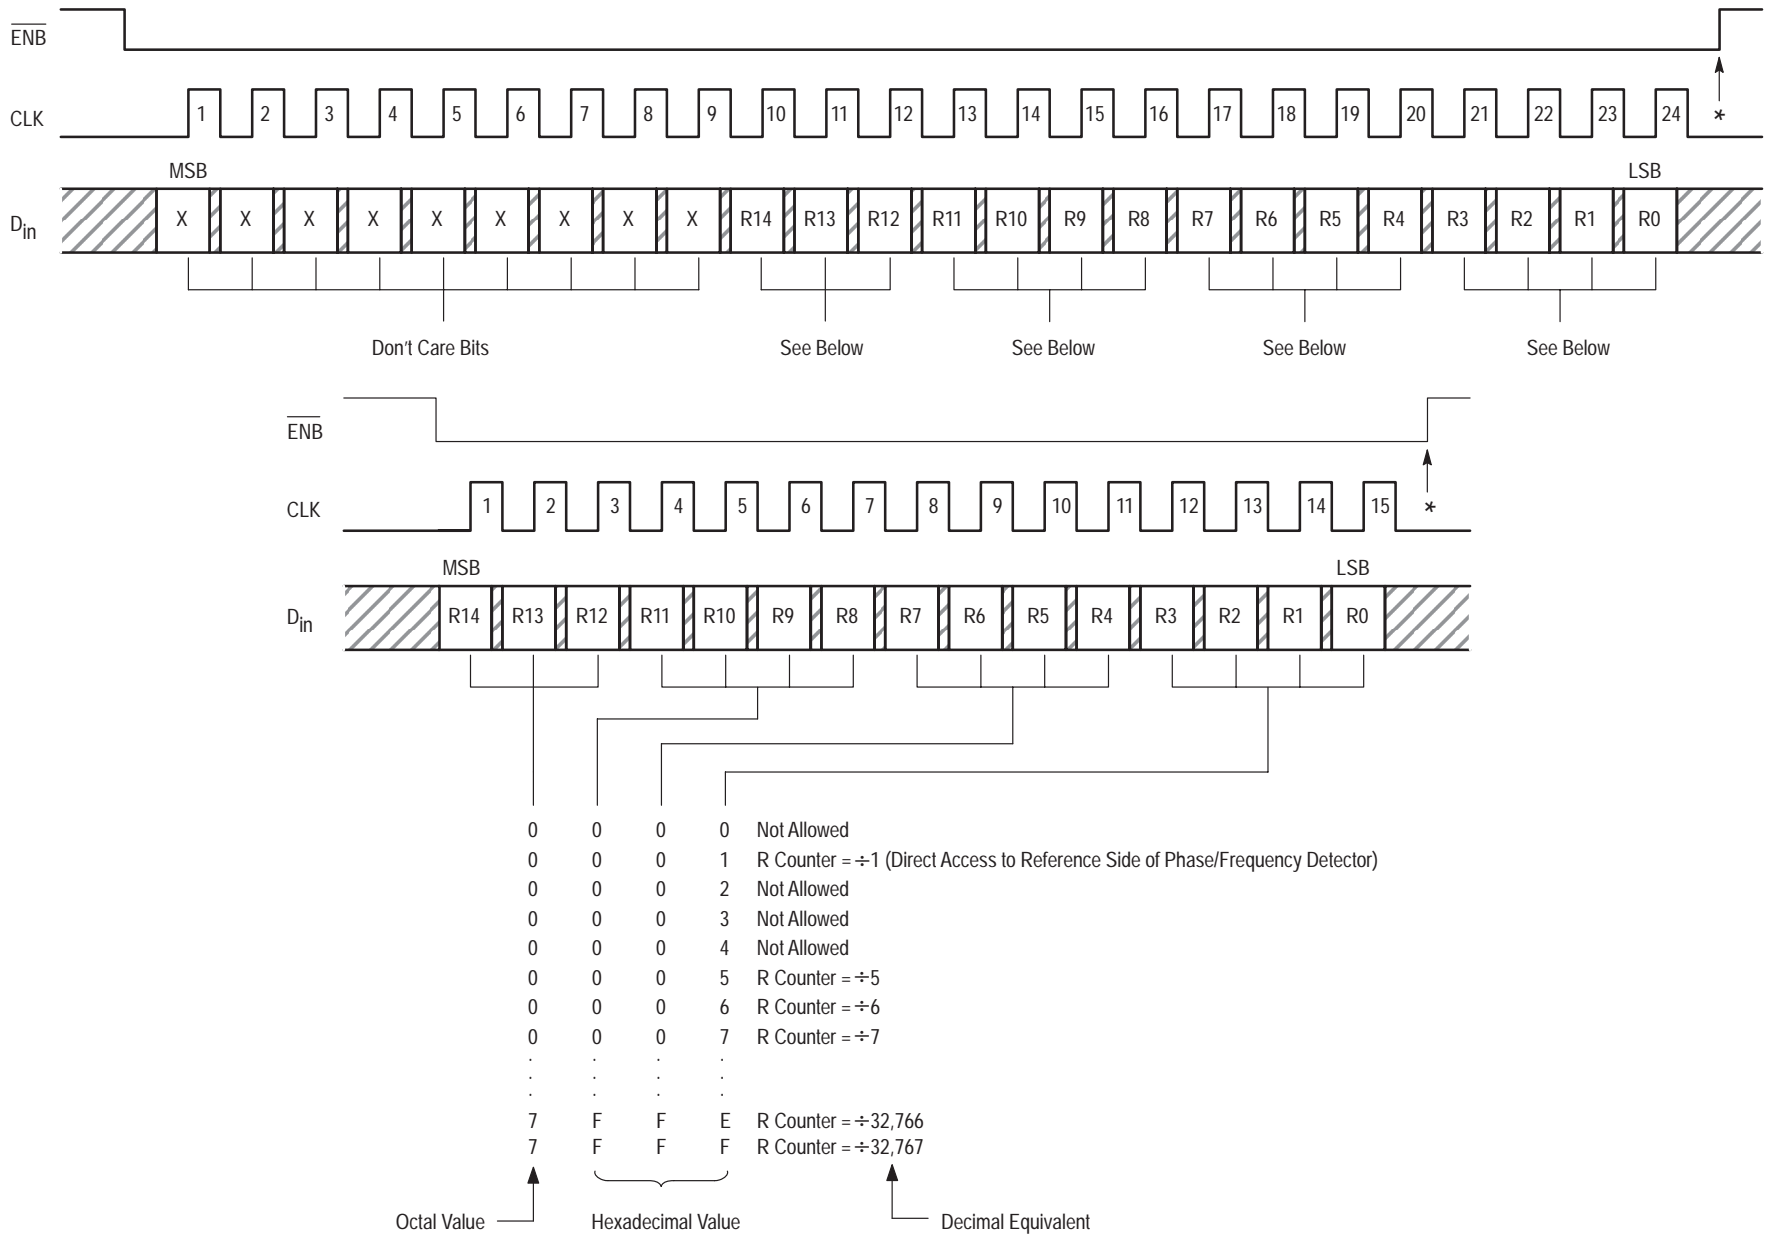

\* At this point, the new byte is transferred to the C register and stored. No other registers are affected.

- C7 — POL: Selects the output polarity of the phase/frequency detectors. When set high, this bit inverts PD<sub>out</sub> and interchanges the  $\phi_R$  function with  $\phi_V$  as depicted in Figure 17. Also see the phase detector output pin descriptions for more information. This bit is cleared low at power up.
- C6 — PDA/B: Selects which phase/frequency detector is to be used. When set high, enables the output of phase/frequency detector A (PD<sub>out</sub>) and disables phase/frequency detector B by forcing  $\phi_R$  and  $\phi_V$  to the static high state. When cleared low, phase/frequency detector B is enabled ( $\phi_R$  and  $\phi_V$ ) and phase/frequency detector A is disabled with PD<sub>out</sub> forced to the high-impedance state. This bit is cleared low at power up.
- C5 — LDE: Enables the lock detector output when set high. When the bit is cleared low, the LD output is forced to a static low level. This bit is cleared low at power up.
- C4 – C2, OSC2 – OSC0: Reference output controls which determine the REF<sub>out</sub> characteristics as shown below. Upon power up, the bits are initialized such that OSC<sub>in</sub>/8 is selected.

C4	C3	C2	REF <sub>out</sub> Frequency
0	0	0	dc (Static Low)
0	0	1	OSC <sub>in</sub>
0	1	0	OSC <sub>in</sub> /2
0	1	1	OSC <sub>in</sub> /4
1	0	0	OSC <sub>in</sub> /8 (POR Default)
1	0	1	OSC <sub>in</sub> /16
1	1	0	OSC <sub>in</sub> /8
1	1	1	OSC <sub>in</sub> /16

- C1 — f<sub>V</sub>E: Enables the f<sub>V</sub> output when set high. When cleared low, the f<sub>V</sub> output is forced to a static low level. The bit is cleared low upon power up.
- C0 — f<sub>R</sub>E: Enables the f<sub>R</sub> output when set high. When cleared low, the f<sub>R</sub> output is forced to a static low level. The bit is cleared low upon power up.

Figure 15. R Register Access and Formats (Either 24 or 15 Clock Cycles Can Be Used)

\* At this point, the new data is transferred to the R register and stored. No other registers are affected.

# MC145170-2

Figure 16. N Register Access and Format (16 Clock Cycles Are Used)

\* At this point, the two new bytes are transferred to the N register and stored. No other registers are affected. In addition, the N and R counters are jam-loaded and begin counting down together.

Figure 17. Phase/Frequency Detectors and Lock Detector Output Waveforms

V<sub>H</sub> = High voltage level

V<sub>L</sub> = Low voltage level

\*At this point, when both f<sub>R</sub> and f<sub>V</sub> are in phase, both the sinking and sourcing output FETs are turned on for a very short interval.

**NOTE:** The PD<sub>Out</sub> generates error pulses during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low-pass filter capacitor. PD<sub>Out</sub>, φ<sub>R</sub>, and φ<sub>V</sub> are shown with the polarity bit (POL) = low; see Figure 14 for POL.

# MC145170-2

## DESIGN CONSIDERATIONS

### CRYSTAL OSCILLATOR CONSIDERATIONS

The following options may be considered to provide a reference frequency to Motorola's CMOS frequency synthesizers.

#### Use of a Hybrid Crystal Oscillator

Commercially available temperature-compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide very stable reference frequencies. An oscillator capable of CMOS logic levels at the output may be direct or dc coupled to OSC<sub>in</sub>. If the oscillator does not have CMOS logic levels on the outputs, capacitive or ac coupling to OSC<sub>in</sub> may be used (see Figures 8a and 8b).

For additional information about TCXOs, visit [motorola.com](http://motorola.com) on the world wide web.

#### Use of the On-Chip Oscillator Circuitry

The on-chip amplifier (a digital inverter) along with an appropriate crystal may be used to provide a reference source frequency. A fundamental mode crystal, parallel resonant at the desired operating frequency, should be connected as shown in Figure 18.

The crystal should be specified for a loading capacitance (C<sub>L</sub>) which does not exceed 20 pF when used at the highest operating frequencies listed in the **Loop Specifications** table. Larger C<sub>L</sub> values are possible for lower frequencies. Assuming R1 = 0 Ω, the shunt load capacitance (C<sub>L</sub>) presented across the crystal can be estimated to be:

$$C_L = \frac{C_{in}C_{out}}{C_{in} + C_{out}} + C_a + C_{stray} + \frac{C1 \times C2}{C1 + C2}$$

where

C<sub>in</sub> = 5.0 pF (see Figure 19)

C<sub>out</sub> = 6.0 pF (see Figure 19)

C<sub>a</sub> = 1.0 pF (see Figure 19)

C1 and C2 = external capacitors (see Figure 18)

C<sub>stray</sub> = the total equivalent external circuit stray capacitance appearing across the crystal terminals

The oscillator can be "trimmed" on-frequency by making a portion or all of C1 variable. The crystal and associated components must be located as close as possible to the OSC<sub>in</sub> and OSC<sub>out</sub> pins to minimize distortion, stray capacitance, stray inductance, and startup stabilization time. Circuit stray capacitance can also be handled by adding the appropriate stray value to the values for C<sub>in</sub> and C<sub>out</sub>. For this approach, the term C<sub>stray</sub> becomes 0 in the above expression for C<sub>L</sub>.

A good design practice is to pick a small value for C1, such as 5 to 10 pF. Next, C2 is calculated. C1 < C2 results in a more robust circuit for start-up and is more tolerant of crystal parameter variations.

Power is dissipated in the effective series resistance of the crystal, R<sub>e</sub>, in Figure 20. The maximum drive level specified by the crystal manufacturer represents the maximum stress that the crystal can withstand without damage or excessive shift in operating frequency. R1 in Figure 18 limits the drive level. The use of R1 is not necessary in most cases.

To verify that the maximum dc supply voltage does not cause the crystal to be overdriven, monitor the output frequency at the REF<sub>out</sub> pin (OSC<sub>out</sub> is not used because loading impacts the oscillator). The frequency should increase very slightly as the dc supply voltage is increased. An overdriven crystal decreases in frequency or becomes unstable with an increase in supply voltage. The operating supply voltage must be reduced or R1 must be increased in value if the overdriven condition exists. The user should note that the oscillator start-up time is proportional to the value of R1.

Through the process of supplying crystals for use with CMOS inverters, many crystal manufacturers have developed expertise in CMOS oscillator design with crystals. Discussions with such manufacturers can prove very helpful (see Table 2).

## PHASE-LOCKED LOOP — LOW PASS FILTER DESIGN

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NR_1C}}$$

$$\zeta = \frac{N\omega_n}{2K_\phi K_{VCO}}$$

$$F(s) = \frac{1}{R_1sC + 1}$$

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC(R_1 + R_2)}}$$

$$\zeta = 0.5 \omega_n \left( R_2C + \frac{N}{K_\phi K_{VCO}} \right)$$

$$F(s) = \frac{R_2sC + 1}{(R_1 + R_2)sC + 1}$$

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NCR_1}}$$

$$\zeta = \frac{\omega_n R_2 C}{2}$$

Assuming Gain A Is Very Large, Then:

$$F(s) = \frac{R_2sC + 1}{R_1sC}$$

### NOTES:

- 8 For (C),  $R_1$  is frequently split into two series resistors; each resistor is equal to  $R_1$  divided by 2. A capacitor  $C_C$  is then placed from the midpoint to ground to further filter the error pulses. The value of  $C_C$  should be such that the corner frequency of this network does not significantly affect  $\omega_n$ .
- 9 The  $\phi_R$  and  $\phi_V$  outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp.
- 10 For the latest information on MC33077 or equivalent, see the Motorola Analog IC web site at <http://www.mot-sps.com/analog>.

### DEFINITIONS:

$N$  = Total Division Ratio in Feedback Loop

$K_\phi$  (Phase Detector Gain) =  $V_{DD} / 4\pi$  volts per radian for  $PD_{out}$

$K_\phi$  (Phase Detector Gain) =  $V_{DD} / 2\pi$  volts per radian for  $\phi_V$  and  $\phi_R$

$$K_{VCO} \text{ (VCO Gain)} = \frac{2\pi\Delta f_{VCO}}{\Delta V_{VCO}}$$

For a nominal design starting point, the user might consider a damping factor  $\zeta \approx 0.7$  and a natural loop frequency  $\omega_n \approx (2\pi f_R / 50)$  where  $f_R$  is the frequency at the phase detector input. Larger  $\omega_n$  values result in faster loop lock times and, for similar sideband filtering, higher  $f_R$ -related VCO sidebands.

# MC145170-2

Figure 21. Example Application

NOTES:

- 1 The φ<sub>R</sub> and φ<sub>V</sub> outputs are fed to an external combiner/loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information. The φ<sub>R</sub> and φ<sub>V</sub> outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp used in the combiner/loop filter.
- 2 For optimum performance, bypass the V<sub>DD</sub> pin to V<sub>SS</sub> (GND) with one or more low-inductance capacitors.
- 3 The R counter is programmed for a divide value = OSC<sub>in</sub>/f<sub>R</sub>. Typically, f<sub>R</sub> is the tuning resolution required for the VCO. Also, the VCO frequency divided by f<sub>R</sub> = N, where N is the divide value of the N counter.
- 4 May be an R-C low-pass filter.
- 5 May be a bipolar transistor.

## MC145170-2

Figure 22. Low Frequency Operation Using dc Coupling

NOTE: The signals at Points A and B may be low-frequency sinusoidal or square waves with slow edge rates or noisy signal edges. At Points C and D, the signals are cleaned up, have sharp edge rates, and rail-to-rail signal swings. With signals as described at Points C and D, the MC145170-2 is guaranteed to operate down to a frequency as low as dc. Refer to the MC74HC14A data sheet for input switching levels and hysteresis voltage range.

## Advance Information

# Dual 550/60 MHz PLL Frequency Synthesizer with DACs and Voltage Multiplier

The MC145181 is a dual frequency synthesizer containing very-low supply voltage circuitry. The device supports two independent loops with a single input reference and operates down to 1.8 V. Phase noise reduction circuitry is incorporated into the device.

The MC145181 operates up to 550 MHz on the main loop and up to 60 MHz on the secondary loop. The device has a 32/33 prescaler for the main loop. Lock detection circuitry for both loops is multiplexed to a single output.

Two 8-bit DACs are powered through a dedicated pin. The DAC supply range is 1.8 to 3.6 V; this voltage may differ from the main supply.

An on-chip voltage multiplier supplies power to the phase/frequency detectors. Thus, in a 2 V application, the detectors are supplied with 4 V power. In 2.6 to 3.6 V applications, the multiplied voltage is regulated at approximately 5 V. The current source/sink phase/frequency detector for the main loop is designed to achieve faster lock times than a conventional detector. Both high and low current outputs are available along with a timer, double buffers, and a MOSFET switch to adjust the external low-pass filter response.

There are several levels of standby which are controllable with a 1-byte transfer through the serial port. Either of the PLLs and/or the reference oscillator may be independently placed in the low-power standby state. In addition, any of the phase/frequency detector outputs may be placed in the floating state to facilitate modulation of the external VCOs. Either DAC may be placed in standby via a 4-byte transfer.

The MC145181 facilitates designing the receiver's first and second local oscillators for ReFLEX™ two-way paging applications. Also, the device accommodates generation of the transmit carrier.

- Operating Frequency
  - Main Loop: 100 to 550 MHz
  - Secondary Loop: 10 to 60 MHz
- Operating Supply Voltage: 1.8 to 3.6 V
- Nominal Supply Current, Both Loops Active: 3 mA
- Maximum Standby Current, All Systems Shut Down: 10  $\mu$ A
- Phase Detector Output Current:
  - 1.8 V Supply — PD<sub>OUT-HI</sub>: 2.8 mA, PD<sub>OUT-LO</sub>: 0.7 mA
  - $\geq 2.5$  V Supply — PD<sub>OUT-HI</sub>: 4.4 mA, PD<sub>OUT-LO</sub>: 1.1 mA
- Two Independent 8-Bit DACs with Separate Supply Pin (Up to 3.6 V)
- Lock Detect Output with Adjustable Lock Indication Window
- Independent R Counters Allow Independent Step Sizes for Each Loop
- Main Loop Divider Range: 992 to 262,143
- Secondary Loop Divider Range: 7 to 8,191
- Fractional Reference Counters Divider Range: 20 to 32,767.5
- Auxiliary Reference Divider with Small-Signal Differential Output — Ratios: 8, 10, 12.5
- Three General-Purpose Outputs
- Direct Interface to Motorola SPI Data Port Up to 10 Mbps

ReFLEX and BitGrabber are trademarks of Motorola, Inc.

Storage Temperature	$T_{stg}$	-65 to 150	°C
Lead Temperature, 1 mm from Case for 10 Seconds	$T_L$	260	°C

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit.

- NOTES:** 1. Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.  
2. ESD (electrostatic discharge) immunity meets Human Body Model (HBM) up to 2000 V. Additional ESD data available upon request.

# MC145181

## 3B. DC ELECTRICAL CHARACTERISTICS

$V_{pos} = 1.8$  to  $3.6$  V, Voltages Referenced to Gnd,  $T_A = -40$  to  $85^\circ\text{C}$ , unless otherwise stated

Parameter	Condition	Symbol	Guaranteed Limit	Unit
Maximum Low-Level Input Voltage ( $D_{in}$ , Clk, $\overline{Enb}$ , Mode, $f_{out}/Pol'$ , $\overline{f_{out}/Pol}$ )	$f_{out}/Pol'$ and $\overline{f_{out}/Pol}$ Configured as Inputs	$V_{IL}$	$0.3 \times V_{pos}$	V
Minimum High-Level Input Voltage ( $D_{in}$ , Clk, $\overline{Enb}$ , Mode, $f_{out}/Pol'$ , $\overline{f_{out}/Pol}$ )	$f_{out}/Pol'$ and $\overline{f_{out}/Pol}$ Configured as Inputs	$V_{IH}$	$0.7 \times V_{pos}$	V
Minimum Hysteresis Voltage (Clk)		$V_{Hys}$	100	mV
Maximum Low-Level Output Voltage (LD, Output A, Output B)	$I_{out} = 20 \mu\text{A}$	$V_{OL}$	0.1	V
Minimum High-Level Output Voltage (LD, Output A, Output B)	$I_{out} = -20 \mu\text{A}$	$V_{OH}$	$V_{pos} - 0.1$	V
Minimum Low-Level Output Current (LD, Output A, Output B)	$V_{out} = 0.3$ V	$I_{OL}$	0.7	mA
Minimum High-Level Output Current (LD, Output A, Output B)	$V_{out} = V_{pos} - 0.3$ V	$I_{OH}$	-0.7	mA
Minimum Low-Level Output Current (Output C)	$V_{out} = 0.2$ V	$I_{OL}$	2.8	mA
Maximum Input Leakage Current ( $D_{in}$ , Clk, $\overline{Enb}$ , Mode, $f_{out}/Pol'$ , $\overline{f_{out}/Pol}$ )	$V_{in} = V_{pos}$ or Gnd; $f_{out}/Pol'$ and $\overline{f_{out}/Pol}$ Configured as Inputs	$I_{in}$	$\pm 1.0$	$\mu\text{A}$
Maximum Output Leakage Current (Output B, Output C)	$V_{out} = V_{pos}$ or Gnd; Output in High-Impedance State	$I_{OZ}$	$\pm 1$	$\mu\text{A}$
Maximum ON Resistance (Output C)	$1.8 \text{ V} \leq V_{pos} < 2.5 \text{ V}$ Supply $2.5 \text{ V} \leq V_{pos} \leq 3.6 \text{ V}$ Supply (Note 1)	$R_{on}$	75 50	$\Omega$
Maximum Standby Supply Current ( $V_{pos}$ and DAC $V_{pos}$ Tied Together)	$V_{in} = V_{pos}$ or Gnd; Outputs Open; Both PLLs in Standby Mode; Oscillator in Standby Mode; DAC1 and DAC2 Output = Zero; Keep-alive Oscillator Off (Notes 2, 3, and 4)	ISTBY	10	$\mu\text{A}$

- NOTES:** 1. For supply voltages restricted to 2.5 to 2.9 V and an ambient temperature range of  $-10$  to  $60^\circ\text{C}$ , Output C has a guaranteed ON resistance range of 23 to 44  $\Omega$ .
2. The total supply current drain for the keep-alive oscillator, voltage multiplier, and regulator is approximately 250  $\mu\text{A}$ .
3. When the Mode pin is tied high, bit C6 must be programmed to a 0 for minimum supply current drain. Otherwise, if C6 = 1, the current drain is approximately 8  $\mu\text{A}$  for a 1.8 V supply and approximately 40  $\mu\text{A}$  for a 3.6 V supply. This restriction on bit C6 does not apply when the Mode pin is tied low.
4. To ensure minimum standby supply current drain, the voltage potential at the  $C_{mult}$  pin must not be allowed to fall below the potential at the  $V_{pos}$  pins. See discussion in Section 5E under  $C_{mult}$ .

## 3C. PD<sub>out-Hi</sub> AND PD<sub>out-Lo</sub> PHASE/FREQUENCY DETECTOR CHARACTERISTICS

Nominal Output Current,  $V_{pos} = 1.8$  V: PD<sub>out-Hi</sub> = 2.8 mA, PD<sub>out-Lo</sub> = 0.7 or 0.35 mA

Nominal Output Current,  $V_{pos} \geq 2.5$  V: PD<sub>out-Hi</sub> = 4.4 mA, PD<sub>out-Lo</sub> = 1.1 or 0.55 mA

R<sub>x</sub> = 2.0 k $\Omega$ , Voltages Referenced to Gnd, Voltage Multiplier ON,  $T_A = -40$  to  $85^\circ\text{C}$

Parameter	Condition	Guaranteed Limit	Unit
Maximum Source Current Variation Part-to-Part (See Note)	$V_{out} = 0.5 \times V_{Cmult}$	$\pm 14$	%
Maximum Sink-versus-Source Mismatch (See Note)	$V_{out} = 0.5 \times V_{Cmult}$	20	%
Output Voltage Range (See Note)	$I_{out}$ Variation $\leq 27\%$	0.6 to $V_{Cmult} - 0.6$ V	V
Maximum Three-State Leakage Current	$V_{out} = 0$ or $V_{Cmult}$	$\pm 50$	nA

**NOTE:** Percentages calculated using the following formula: (Maximum Value - Minimum Value) / Maximum Value.

## 3D. PD<sub>out'</sub> PHASE/FREQUENCY DETECTOR CHARACTERISTICS

$V_{pos} = 1.8$  to  $3.6$  V, Voltages Referenced to Gnd, Voltage Multiplier ON,  $T_A = -40$  to  $85^\circ\text{C}$

Parameter	Condition	Guaranteed Limit	Unit
Minimum Low-Level Output Current	$V_{out} = 0.3$ V	0.3	mA
Minimum High-Level Output Current	$V_{out} = V_{Cmult} - 0.3$ V	-0.3	mA
Maximum Three-State Leakage Current	$V_{out} = 0$ or $V_{Cmult}$	$\pm 50$	nA

# MC145181

## 3E. DAC CHARACTERISTICS

$V_{pos} = 1.8$  to  $3.6$  V, DAC  $V_{pos} = 1.8$  to  $3.6$  V;  $T_A = -40$  to  $85^\circ\text{C}$

Parameter	Condition	Guaranteed Limit	Unit
Resolution		8	Bits
Maximum Integral Nonlinearity		$\pm 1$	LSB
Maximum Offset Voltage from Gnd	No External Load	1	LSB
Maximum Offset Voltage from DAC $V_{pos}$	No External Load	2	LSB
Maximum Output Impedance	Over Entire Output Range, Including Zero Output (which is Low-power Standby)	130	k $\Omega$
Maximum Standby Current	Zero Output, No External Load	(See $I_{STBY}$ in Section 3B)	
Maximum Supply Current per DAC @ DAC $V_{pos}$ pin	Except with Zero Output, No External Load	(DAC $V_{pos}$ ) / 36	mA

## 3F. VOLTAGE MULTIPLIER AND KEEP-ALIVE OSCILLATOR CHARACTERISTICS

Voltages Referenced to Gnd,  $T_A = -40$  to  $85^\circ\text{C}$

Parameter	Condition	Guaranteed Limit	Unit
Voltage Multiplier Output Voltage	5 MHz Refresh Rate, 100 $\mu\text{A}$ Continuous Sourcing, Measured at $C_{mult}$ pin $V_{pos} = 1.8$ V $V_{pos} = 3.6$ V	3.32 to 3.78 4.75 to 5.35	V
Keep-alive Refresh Frequency	$V_{pos} = 1.8$ to $3.6$ V	300 to 700	kHz

## 3G. DYNAMIC CHARACTERISTICS OF DIGITAL PINS

$V_{pos} = 1.8$  to  $3.6$  V,  $T_A = -40$  to  $85^\circ\text{C}$ , Input  $t_r = t_f = 10$  ns,  $C_L = 25$  pF

Parameter	Figure No.	Symbol	Guaranteed Limit	Unit
Serial Data Clk Frequency NOTE: Refer to Clk $t_w$ Below	1	$f_{clk}$	dc to 10	MHz
Maximum Propagation Delay, $\overline{Enb}$ to Output A (Selected as General-Purpose Output)	2, 7	$t_{PLH}$ , $t_{PHL}$	200	ns
Maximum Propagation Delay, $\overline{Enb}$ to Output B	2, 3, 7, 8	$t_{PLH}$ , $t_{PHL}$ , $t_{PZL}$ , $t_{PLZ}$ , $t_{PZH}$ , $t_{PHZ}$	200	ns
Maximum Propagation Delay, $\overline{Enb}$ to Output C	4, 8	$t_{PZL}$ , $t_{PLZ}$	200	ns
Maximum Output Transition Time, Output A; Output B with Active Pullup and Pulldown	2, 7	$t_{TLH}$ , $t_{THL}$	75	ns
Minimum Setup and Hold Times, $D_{in}$ versus Clk	5	$t_{su}$ , $t_h$	30	ns
Minimum Setup, Hold, and Recovery Times, $\overline{Enb}$ versus Clk	6	$t_{su}$ , $t_h$ , $t_{rec}$	100	ns
Minimum Pulse Width, Inactive (High) Time, $\overline{Enb}$	6	$t_w$	*	cycles
Minimum Pulse Width, Clk	1	$t_w$	50	ns
Maximum Input Capacitance — $D_{in}$ , CLK, $\overline{Enb}$		$C_{in}$	10	pF

\*For Hr register access, the minimum limit is 20  $Osc_e$  cycles.

For  $Hn'$  register access, the minimum limit is 27  $f_{in'}$  cycles.

For N register access, the minimum limit is 20  $Osc_e$  cycles + 99  $f_{in}$  cycles.

When the timer is used for adapt, the minimum limit after the second N register access and before the next register access is the time-out interval + 99  $f_{in}$  cycles.

## 4. DEVICE OVERVIEW

Refer to the Block Diagram in Section 1.

### 4A. SERIAL INTERFACE AND REGISTERS

The serial interface is comprised of a Clock pin (Clk), a Data In pin ( $D_{in}$ ), and an Enable pin ( $\overline{Enb}$ ). Information on the data input pin is shifted into a shift register on the low-to-high transition of the serial clock. The data format is most significant bit (MSB) first. Both Clk and  $\overline{Enb}$  are Schmitt-triggered inputs.

The R and N registers contain counter divide ratios for the main loop, PLL. The R' and N' registers contain counter divide ratios for the secondary loop, PLL'. Additional control bits are located in the R', N, and C registers. The D register controls the digital-to-analog converters (DACs). Random access is allowed to the N, R', Hr, Hn', D, and C registers.

Two 16-bit holding registers, Hr and Hn', feed registers R and N', respectively. [The three least significant bits (LSBs) of the Hn' register are not used.] The R and N' registers determine the divide ratios of the R and N' counters, respectively. Thus, the information presented to the R and N' counters is double-buffered. Using the proper programming sequence, new divide ratios may be presented to the N, R, and N' counters; simultaneously.

$\overline{Enb}$  is used to activate the data port and allow transfer of data. To ensure that data is accepted by the device, the  $\overline{Enb}$  signal line must initially be a high voltage (not asserted), then make a transition to a low voltage (asserted) prior to the occurrence of a serial clock, and must remain asserted until after the last serial clock of the burst. Serial data may be transferred in an SPI format (while  $\overline{Enb}$  remains asserted). Data is transferred to the appropriate register on the rising edge of  $\overline{Enb}$  (see Table 1). "Short shifting", depicted as BitGrabber™ in the table, allows access to certain registers without requiring address bits. When  $\overline{Enb}$  is inactive (high), Clk is inhibited from shifting the shift register.

The serial input pins may NOT be driven above the supply voltage applied to the  $V_{POS}$  pins.

### 4B. REFERENCE INPUT AND COUNTERS CIRCUITS

#### Reference (Oscillator) Circuit

For the Colpitts reference oscillator, one pin ties to the base ( $Osc_b$ , pin 32) and the other ties to the emitter ( $Osc_e$ , pin 1), of an on-chip NPN transistor. In addition, the reference circuit may be operated in the external reference (XRef) mode as selectable via bit C6 when the Mode pin is high.

The  $Osc_b$  and  $Osc_e$  pins support an external fundamental or overtone crystal. The output of the oscillator is routed to both the reference counter for the main loop (R counter) and the reference counter for the secondary loop (R' counter).

In a second mode, determined by bit C6 being 1 and the Mode pin being high,  $Osc_e$  is an input which accepts an ac-coupled signal from a TCXO or other source.  $Osc_b$  must be floated. If the Mode pin is low, this "XRef mode" is not allowed.

#### Reference Counter for Main Loop

Main reference counter R divides down the frequency at  $Osc_e$  and feeds the phase/frequency detector for the main loop. The detector feeds the two charge pumps with outputs  $PD_{out-Hi}$  and  $PD_{out-Lo}$ . The division ratio of the R counter is determined by bits in the R register.

#### Reference Counter for Secondary Loop

Secondary reference counter R' divides down the frequency at  $Osc_e$  and feeds the phase/frequency detector for the secondary loop. The detector output is  $PD_{out}'$ . The division ratio of the R' counter is determined by the 16 LSBs of the R' register.

The R' counter has a special mode to provide a frequency output at pins  $f_{out}$  and  $\overline{f}_{out}$  (differential outputs). These are low-jitter ECL-type outputs. With the Mode pin low, software control allows the  $Osc_e$  frequency to be divided-by-8, -10, or -12.5 and routed to the  $f_{out}$  pins. This output is derived by tapping off of a front-end stage of the R' counter and feeding the auxiliary counter which provides the divided-down frequency. The chip must have the Mode pin low, which activates the  $f_{out}$  pins. The actual R' divide ratio must be divisible by 2 or 2.5 when the  $f_{out}$  pins are activated. There is no such restriction when the Mode pin is high. See Section 6D, R' Register.

### 4C. LOOP DIVIDER INPUTS AND COUNTER CIRCUITS

#### $f_{in}$ Inputs and Counter Circuit

$f_{in}$  and  $\overline{f}_{in}$  are high-frequency inputs to the amplifier which feeds the N counter. A small signal can feed these inputs either differentially or single-ended.

The N counter divides down the external VCO frequency for the main loop. (The divide ratio of the N counter is also known as the loop multiplying factor.) The divide ratio of this counter is determined by the 18 LSBs of the N register. The output of the N counter feeds the phase/frequency detector for the main loop.

#### $f_{in}'$ Input and Counter Circuit

$f_{in}'$  is the high-frequency input to the amplifier which feeds the N' counter. A small signal can feed this input single-ended.

The N' counter divides down the external VCO frequency for the secondary loop. (The divide ratio of the N' counter is also known as the loop multiplying factor.) The divide ratio of this counter is determined by bits in the N' register. The output of the N' counter feeds the phase/frequency detector for the secondary loop.

### 4D. VOLTAGE MULTIPLIER AND KEEP-ALIVE CIRCUITS

The voltage multiplier produces approximately two times the voltage present at the  $V_{POS}$  pins over a supply range of 1.8 V to about 2.5 V. With a supply range of approximately 2.5 V to 3.6 V, the elevated voltage is regulated/limited to approximately 5 V. The elevated voltage, present at the  $C_{mult}$

pin, is applied to both phase detectors. An external capacitor to Gnd is required on the  $C_{mult}$  pin. The other capacitors required for the multiplier are on-chip.

A capacitor to Gnd is also required on the  $C_{reg}$  pin. The voltage on this pin is equal to the voltage on the  $V_{pos}$  pins over a supply range of 1.8 V to about 2.5 V. The voltage on  $C_{reg}$  is limited to approximately 2.5 V maximum when the  $V_{pos}$  pins exceed 2.5 V.

The refresh rate determines the repetition rate that the capacitors for the voltage multiplier are charged. Refresh is normally derived off of the signal present at the  $Osc_e$  pin, through a divider which is part of the voltage multiplier and regulator circuitry. The refresh rate is controlled via bits in the  $R'$  register.

When the reference oscillator circuit is placed in standby, an on-chip keep-alive oscillator assists in maintaining the elevated voltage on the phase detectors. The keep-alive refresh rate is per the spec table in Section 3F.

If desired, the keep-alive oscillator can be inhibited from turning on, by placing the multiplier in the inactive state via  $R'$  register bits. This causes the phase/frequency detector voltage to bleed off while in standby, but has the advantage of achieving the lowest supply current if all other sections of the chip are shut down.

#### 4E. PHASE/FREQUENCY DETECTORS

##### Detector for Main Loop

The detector for the main loop senses the phase and frequency difference between the outputs of the R and N counters. The detector feeds both a high-current charge pump with output  $PD_{out-Hi}$  and a low-current charge pump with output  $PD_{out-Lo}$ .

The charge pumps can be operated in three conventional manners as controlled by bits in the N register.  $PD_{out-Lo}$  can be enabled with  $PD_{out-Hi}$  inhibited. Conversely,  $PD_{out-Hi}$  can be enabled with  $PD_{out-Lo}$  inhibited. Both outputs can be enabled and tied together externally for maximum charge pump current. Finally, both outputs can be inhibited. In this last case, they float. The outputs can also be forced to the floating state by a bit in the C register. This facilitates introduction of modulation into the VCO input.

The charge pumps can be operated in an adapt mode as controlled by bits in the N register. The bits essentially program a timer which determines how long  $PD_{out-Hi}$  is active. After the time-out,  $PD_{out-Hi}$  floats and  $PD_{out-Lo}$  becomes active. In addition, a second set of R and N counter values can be engaged after the time-out. For more information, see Table 16 and Section 8, **Programmer's Guide**.

##### Detector for Secondary Loop

The detector for the secondary loop senses the phase and frequency difference between the outputs of the  $R'$  and  $N'$  counters. Detector output  $PD_{out}'$  is a voltage-type output with a three-state push-pull driver.

The output can be forced to the floating state by a bit in the C register. This facilitates introduction of modulation into the VCO input.

#### 4F. LOCK DETECTORS

Window counters in each of the lock detector circuits determine the lock detector phase threshold for PLL and PLL'. The window counter divide ratio for the main loop's lock detector is controlled via a bit in the N register. The window counter divide ratio for the secondary loop is not controllable by the user.

The lock detector window determines a minimum phase difference which must occur before the Lock Detect pin goes high. Note that the lock detect signals for each loop drive an AND gate, which then feeds the LD pin. The LD pin indicates the condition of both loops, or the one active loop if the other is in standby. If both loops are in standby, LD is low indicating unlocked.

#### 4G. DACs

The two independent 8-bit DACs facilitate crystal oscillator trimming and PA output power control. They are also suitable for any general-purpose use.

Each DAC utilizes an R-2R ladder architecture. The output pins, DAC1 and DAC2, are directly connected to the ladder; that is, there is no on-chip buffer.

The DAC outputs are determined by the contents of the D register. When a DAC output is zero scale, it is also in a low-power mode. The power-on reset (POR) circuit initializes the DACs in the low-power mode upon power up.

#### 4H. GENERAL-PURPOSE OUTPUTS

There are three outputs which may be used as port expanders for a microcontroller unit (MCU).

Output A is actually a multi-purpose output with a push-pull output driver. See Table 2 for details.

Output B is a three-state output. The state of Output B depends on two bits; one of these bits also controls whether the main PLL is in standby or not. See Table 5 for details.

Output C is an open-drain output. The state of this output is controlled by one bit per Table 4. Output C is specified with a guaranteed ON resistance, and thus, may be used in an analog fashion.

## 5. PIN DESCRIPTIONS

## 5A. DIGITAL PINS

 $\overline{\text{Enb}}$ ,  $\text{D}_{\text{in}}$ , and  $\text{Clk}$ 

## Pins 5, 6, and 7 — Serial Data Port Inputs

The  $\overline{\text{Enb}}$  input is used to activate the serial interface to allow the transfer of data to the device. To transfer data to the device, the  $\overline{\text{Enb}}$  pin must be low during the interval that the data is being clocked in. When  $\overline{\text{Enb}}$  is taken back high (inactive), data is transferred to the appropriate register depending either on the data stream length or address bits. The C, Hr, and N registers can be accessed using either a unique data stream length (BitGrabber) or by using address bits (Conventional). The D,  $\text{Hn}'$ , and  $\text{R}'$  registers can only be accessed using address bits. See Table 1.

The bit stream begins with the MSB and is shifted in on the low-to-high transition of  $\text{Clk}$ . The bit pattern is 1 byte (8 bits) long to access the C register, 2 bytes (16 bits) to access the Hr register, or 3 bytes (24 bits) to access the N register. A bit pattern of 4 bytes (32 bits) is used to access the registers when using address bits. The device has double buffers for storage of the  $\text{N}'$  and R counter divide ratios. One double buffer is composed of the Hr register which feeds the R register. An Hr to R register transfer occurs whenever the N register is written. The other double buffer is the  $\text{Hn}'$  register which feeds the  $\text{N}'$  register. An  $\text{Hn}'$  to  $\text{N}'$  register transfer occurs whenever the N register is written. Thus, new divide ratios may be presented to the R,  $\text{N}'$ , and N counters simultaneously.

Transitions on  $\overline{\text{Enb}}$  must not be attempted while  $\text{Clk}$  is high. This puts the device out of synchronization with the microcontroller. Resynchronization occurs whenever  $\overline{\text{Enb}}$  is high (inactive) and  $\text{Clk}$  is low.

Data is retained in the registers over a supply range of 1.8 to 3.6 V. The bit-stream formats are shown in Figures 13 through 18.

## LD

## Pin 8 — Lock Detectors Output

This signal is the logical AND of the lock detect signals from both PLL and  $\text{PLL}'$ . For the main PLL, the phase window that defines “lock” is programmable via bit N22. The phase window for the secondary  $\text{PLL}'$  is not programmable.

If either PLL or  $\text{PLL}'$  is in standby, LD indicates the lock condition of the active loop only. If both loops are in standby, the LD output is a static low level.

Each PLL's lock detector is in the high state when the respective loop is locked (the inputs to the phase detector being the same phase and frequency). The lock detect signal is in the low state when a loop is out of lock. See Figure 19.

Upon power up, the LD pin indicates a *not locked* condition. The LD pin is a push-pull CMOS output. If unused, LD should be left open.

## Output A

## Pin 9 — Multiple-Purpose Digital Output

Depending on control bits  $\text{R}'21$  and  $\text{R}'20$ , Output A is selectable by the user as a general-purpose output (either high or low level),  $f_{\text{R}}$  (output of main reference counter),  $f_{\text{R}'}$  (output of secondary reference counter), or a phase detector pulse indicator for both loops. When selected as general-purpose output, bit C7 determines whether the output is a high or low level per Table 2. When configured as  $f_{\text{R}}$ ,  $f_{\text{R}'}$ , or phase detector pulse, Output A appears as a normally low signal and pulses high.

Output A is a slow-rate limited CMOS totem-pole output. If unused, Output A should be left open.

**Table 1. Register Access**  
(LSBs are C0, R0, N0, D0,  $\text{R}'0$ , and  $\text{N}'0$ )

Access Type	Accessed Register	Address Nibble	Number of Clocks	Register Bit Nomenclature	Figure No.
BitGrabber	C	—	8	C7, C6, C5, ..., C0	13
BitGrabber	Hr	—	16	R15, R14, R13, ..., R0	14
BitGrabber	N	—	24	N23, N22, N21, ..., N0	15
Conventional	C	\$0	32	C7, C6, C5, ..., C0	13
Conventional	Hr	\$1	32	R15, R14, R13, ..., R0	14

Conventional	D	\$3	32	D15, D14, D13, ..., D0	18
Conventional	$\text{R}'$	\$5	32	$\text{R}'23$ , $\text{R}'22$ , $\text{R}'21$ , ..., $\text{R}'0$	16
Conventional	$\text{Hn}'$	\$4	32	$\text{N}'15$ , $\text{N}'14$ , $\text{N}'13$ , ..., $\text{N}'0$	17

**NOTE:** \$0 denotes hexadecimal zero, \$1 denotes hexadecimal one, etc.

**Table 2. Output A Configuration**

Bit R'21	Bit R'20	Bit C7	Function of Output A
0	0	0	General-Purpose Output, Low Level
0	0	1	General-Purpose Output, High Level
0	1	x	f <sub>R</sub>
1	0	x	f <sub>R'</sub>
1	1	x	Phase Detector Pulse Indicator

**Mode**

**Pin 10 — Mode Input**

When the Mode pin is tied low (approximately Gnd), the pair of pins named f<sub>out</sub>/Pol' and f<sub>out</sub>/Pol become outputs f<sub>out</sub> and f<sub>out</sub>. As such, these pins are the divided down reference frequency. The division ratio is controlled by bits per Table 6. In addition, when Mode is low, the R' counter is preceded by a fixed-divide prescaler. Also, only a crystal may be used at pins Osc<sub>B</sub> and Osc<sub>E</sub>; an external reference, such as a TCXO, should not be used to drive either pin. The default on the phase detector polarity is positive. See the summary in Table 3.

When the Mode pin is tied high (approximately V<sub>POS</sub>), the pair of pins named f<sub>out</sub>/Pol' and f<sub>out</sub>/Pol become inputs Pol' and Pol. As such, these pins control the polarity of the phase/frequency detectors for PLL' and PLL, respectively. In addition, when Mode is high, the R' counter is preceded by a dual-modulus prescaler. Therefore, the R' counter is completely programmable per Figure 16. Also, either a crystal or TCXO may be used with the device. See the summary in Table 3.

**Table 3. Mode Pin Summary**

Attribute	Mode Pin = Low Level	Mode Pin = High Level
f <sub>out</sub> /Pol' pin	Pin is f <sub>out</sub> output; polarity of phase detector' is positive	Pin is Pol' input and controls polarity of phase detector'
f <sub>out</sub> /Pol pin	Pin is f <sub>out</sub> output; polarity of phase detector is positive	Pin is Pol input and controls polarity of phase detector
Oscillator circuit	Supports a crystal only	Supports crystal or accommodates TCXO
R' counter	Programmable in increments of 2 or 2.5	Programmable in increments of 0.5
Output B pin	State of pin controlled by Bit C6	Pin not used, Bit C6 controls whether crystal or TCXO is accommodated

**Output C**

**Pin 16 — General-Purpose Digital Output**

This pin is controllable by bit C5 as either low level or high impedance per Table 4.

The output driver is an open-drain N-channel MOSFET connected to Gnd. The ESD (electrostatic discharge) protection circuit for this pin is tied to Gnd and V<sub>POS</sub>. Thus,

voltages above V<sub>POS</sub> are clipped at approximately 0.7 V above V<sub>POS</sub>. If unused, Output C should be left open.

**Table 4. Output C Programming**

Bit C5	State of Output C Pin
0	Low level (ON resistance per Electrical Table)
1	High impedance (leakage per Electrical Table)

**Output B**

**Pin 25 — General-Purpose Digital Output**

This pin is controllable by bits C6 and C1 as either low level, high level, or high impedance per Table 5. Note that whenever the main PLL is placed in standby by bit C1, Output B is forced to high impedance. The three-state MOSFET output is slew-rate limited. If unused, Output B should be left open.

**Table 5. Output B Programming**

Bit C6	Bit C1	State of Output B Pin	Condition of Main PLL
0	0	Low level	Active
0	1	High impedance*	Standby*
1	0	High level	Active
1	1	High impedance	Standby

\*Power-up default.

**f<sub>out</sub>/Pol' and f<sub>out</sub>/Pol**

**Pins 28 and 27 — Dual-purpose Outputs/Inputs**

These pins are outputs when the Mode pin is low and inputs when the Mode pin is high.

When the Mode pin is low, these pins are small-signal differential outputs f<sub>out</sub> and f<sub>out</sub> with a frequency derived from the signal present at the Osc<sub>E</sub> pin. The frequency of the output signal is per Table 6. If this function is not needed, the Mode pin should be tied high, which minimizes supply current. In this case, these inputs must be tied high or low per Tables 7 and 8.

**Table 6. f<sub>out</sub> and f<sub>out</sub> Frequency (Mode Pin = Low)**

Bit N23	Bit R'1	Bit R'0	Output Frequency
0	0	0	Osc <sub>E</sub> divided by 10
0	0	1	Osc <sub>E</sub> divided by 12.5
0	1	0	Osc <sub>E</sub> divided by 12.5
0	1	1	Osc <sub>E</sub> divided by 12.5
1	0	0	Osc <sub>E</sub> divided by 8
1	0	1	Osc <sub>E</sub> divided by 10
1	1	0	Osc <sub>E</sub> divided by 10
1	1	1	Osc <sub>E</sub> divided by 10

When the Mode pin is high, these pins are digital inputs Pol' and Pol which control the polarity of the phase/frequency detectors. See Tables 7 and 8. Positive polarity is used when an increase in an external VCO control voltage input causes an increase in VCO output frequency. Negative polarity is used when a decrease in an external VCO control voltage input causes an increase in VCO output frequency.

**Table 7. Main Phase/Frequency Detector Polarity (Mode Pin = High)**

Mode Pin	Pol Pin	Main Detector Polarity (PD <sub>out-Lo</sub> and PD <sub>out-Hi</sub> )
High	Low	Positive
High	High	Negative
Low	*	Positive

\*Pin configured as an output; should not be driven.

**Table 8. Secondary Phase/Frequency Detector Polarity (Mode Pin = High)**

Mode Pin	Pol' Pin	Secondary Detector Polarity (PD <sub>out'</sub> )
High	Low	Positive
High	High	Negative
Low	*	Positive

\*Pin configured as an output; should not be driven.

**5B. REFERENCE PINS**

**Osc<sub>e</sub> and Osc<sub>b</sub>**

**Pins 1 and 32 — Reference Oscillator Transistor Emitter and Base**

These pins can be configured to support an external crystal in a Colpitts oscillator configuration. The required connections for the crystal circuit are shown in the **Crystal Oscillator Considerations** section.

Additionally, the pins can be configured to accept an external reference frequency source, such as a TCXO. In this case, the reference signal is ac coupled into Osc<sub>e</sub> and the Osc<sub>b</sub> pin is left floating. See Figure 11.

Bit C6 and the Mode input pin control the configuration of these pins per Table 9.

**Table 9. Reference Configuration**

Mode Input Pin	Bit C6	Reference Configuration	Comment
Low	X	Supports Crystal (default)	C6 used to control Output B*
High	0	Supports Crystal	Output B not useful
High	1	Requires External Reference	Output B not useful

\*See Table 5.

**5C. LOOP PINS**

**f<sub>in</sub> and f<sub>in</sub><sup>̄</sup>**

**Pins 12 and 13 — Frequency Input for Main Loop (PLL)**

These pins feed the on-chip RF amplifier which drives the high-speed N counter. This input may be fed differentially. However, it is usually used in a single-ended configuration with f<sub>in</sub> driven while f<sub>in</sub><sup>̄</sup> is tied to a good RF ground (via a capacitor). The signal source driving this input must be ac coupled and originates from an external VCO.

The sensitivity of the RF amplifier is dependent on frequency as shown in the Loop Specifications table. Sensitivity of the f<sub>in</sub> input is specified as a level across a 50 Ω load driven by a 50 Ω source. A VCO that can drive a load within the data sheet limits can also drive f<sub>in</sub>. Usually, to avoid load pull and resultant frequency modulation of the VCO, f<sub>in</sub> is lightly coupled by a small value capacitor and/or a resistor. See the applications circuit of Figure 65.

**f<sub>in</sub>'**

**Pin 30 — Frequency Input for Secondary Loop (PLL')**

This pin feeds the on-chip RF amplifier which drives the high-speed N' counter. This input is used in a single-ended configuration. The signal source driving this input must be ac coupled and originates from an external VCO.

The sensitivity of the RF amplifier is dependent on frequency as shown in the Loop Specifications table. Sensitivity of the f<sub>in</sub>' input is specified as a level across a 50 Ω load driven by a 50 Ω source. A VCO that can drive a load within the data sheet limits can also drive f<sub>in</sub>'. Usually, to avoid load pull and resultant frequency modulation of the VCO, f<sub>in</sub>' is lightly coupled by a small value capacitor and/or a resistor. See the applications circuit of Figure 65.

If the secondary loop is not used, PLL' should be placed in standby and f<sub>in</sub>' should be left open.

**PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub>**

**Pins 19 and 20 — Phase/Frequency Detector Outputs for Main Loop (PLL)**

Each pin is a three-state current source/sink/float output for use as a loop error signal when combined with an external low-pass loop filter. Under bit control, PD<sub>out-Lo</sub> has either one-quarter or one-eighth the output current of PD<sub>out-Hi</sub> per Table 10. The detector is characterized by a linear transfer function (no dead zone). The polarity of the detector is controllable. The operation of the detector is described below and shown in Figure 20.

**Table 10. Current Ratio of PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub>**

Bit N18	Output Current Ratio PD <sub>out-Hi</sub> :PD <sub>out-Lo</sub> (Gain Ratio)
0	4 : 1
1	8 : 1

When the Mode pin is high, positive polarity occurs when the Pol pin is low. Also, when the Mode pin is low, polarity

defaults to positive. Positive polarity is described below.  $f_V$  is the output of the main loop's VCO divider (N counter).  $f_R$  is the output of the main loop's reference divider (R counter).

- (a) Frequency of  $f_V > f_R$  or phase of  $f_V$  leading  $f_R$ : current-sinking pulses from a floating state.
- (b) Frequency of  $f_V < f_R$  or phase of  $f_V$  lagging  $f_R$ : current-sourcing pulses from a floating state.
- (c) Frequency and phase of  $f_V = f_R$ : essentially a floating state, voltage at pin determined by loop filter.

When the Mode pin is high, negative polarity occurs when the Pol pin is high. Negative polarity is described below.  $f_V$  is the output of the main loop's VCO divider (N counter).  $f_R$  is the output of the main loop's reference divider (R counter).

- (a) Frequency of  $f_V > f_R$  or phase of  $f_V$  leading  $f_R$ : current-sourcing pulses from a floating state.
- (b) Frequency of  $f_V < f_R$  or phase of  $f_V$  lagging  $f_R$ : current-sinking pulses from a floating state.
- (c) Frequency and phase of  $f_V = f_R$ : essentially a floating state, voltage at pin determined by loop filter.

These outputs can be enabled and disabled by bits in the C and N registers. Placing the main PLL in standby (bit C1 = 1) forces the detector outputs to a floating state. In addition, setting the PD Float bit (bit C4 = 1) forces the detector outputs to a floating state while allowing the counters to run for the main PLL. For selection of the outputs, see Table 11.

The phase detector gain (in amps per radian) =  $PD_{out}$  current (in amps) divided by  $2\pi$ .

If a detector output is not used, that pin should be left open.

Table 11. Selection of Main Detector Outputs

Bit N21	Bit N20	Bit N19	Result
0	0	0	Both outputs not enabled
0	0	1	$PD_{out-Lo}$ enabled
0	1	0	$PD_{out-Hi}$ enabled
0	1	1	Both $PD_{out-Lo}$ and $PD_{out-Hi}$ enabled
1	0	0	$PD_{out-Hi}$ enabled for 16 $f_R$ cycles only, then $PD_{out-Lo}$ enabled
1	0	1	$PD_{out-Hi}$ enabled for 32 $f_R$ cycles only, then $PD_{out-Lo}$ enabled
1	1	0	$PD_{out-Hi}$ enabled for 64 $f_R$ cycles only, then $PD_{out-Lo}$ enabled
1	1	1	$PD_{out-Hi}$ enabled for 128 $f_R$ cycles only, then $PD_{out-Lo}$ enabled

- NOTES: 1. When a detector output is not enabled, it is floating.  
 2. Setting bit N21 = 1 places the IC in an adapt mode and engages a timer.

**PDout'**  
**Pin 23 — Phase/Frequency Detector Output for Secondary Loop (PLL')**

This pin is a three-state voltage output for use as a loop error signal when combined with an external low-pass loop filter. The detector is characterized by a linear transfer function (no dead zone). The polarity of the detector is controllable. The operation of the detector is described below and shown in Figure 21.

When the Mode pin is high, positive polarity occurs when the Pol' pin is low. Also, when the Mode pin is low, polarity defaults to positive. Positive polarity is described below.  $f_V'$  is the output of the secondary loop's VCO divider (N' counter).  $f_R'$  is the output of the secondary loop's reference divider (R' counter.)

- (a) Frequency of  $f_V' > f_R'$  or phase of  $f_V'$  leading  $f_R'$ : negative pulses from high impedance.
- (b) Frequency of  $f_V' < f_R'$  or phase of  $f_V'$  lagging  $f_R'$ : positive pulses from high impedance.
- (c) Frequency and phase of  $f_V' = f_R'$ : essentially a high-impedance state, voltage at pin determined by loop filter.

When the Mode pin is high, negative polarity occurs when the Pol' pin is high. Negative polarity is described below.  $f_V'$  is the output of the secondary loop's VCO divider (N' counter).  $f_R'$  is the output of the secondary loop's reference counter (R' counter.)

- (a) Frequency of  $f_V' > f_R'$  or phase of  $f_V'$  leading  $f_R'$ : positive pulses from high impedance.
- (b) Frequency of  $f_V' < f_R'$  or phase of  $f_V'$  lagging  $f_R'$ : negative pulses from high impedance.
- (c) Frequency and phase of  $f_V' = f_R'$ : essentially a high-impedance state, voltage at pin determined by loop filter.

This output can be enabled and disabled by bits in the C register. Placing the secondary PLL' in standby (bit C0 = 1) forces the detector output to a high-impedance state. In addition, setting the PD' Float bit (bit C3 = 1) forces the detector output to a high-impedance state while allowing the counters to run for PLL'.

The phase detector gain (in volts per radian) =  $C_{mult}$  voltage (in volts) divided by  $4\pi$ .

If the secondary loop is not used, PLL' should be placed in standby and  $PD_{out}'$  should be left open.

**5D. ANALOG OUTPUTS**

**DAC1 and DAC2**  
**Pins 3 and 4 — Digital-to-Analog Converter Outputs**

These are independent outputs of the two 8-bit D/A converters. The output voltage is determined by bits in the D register. Each output is a static level with an output impedance of approximately 100 k $\Omega$ .

The DACs may be used for crystal oscillator trimming, PA (power amplifier) output power control, or other general-purpose use.

If a DAC output is not used, the pin should be left open.

## 5E. EXTERNAL COMPONENTS

**R<sub>x</sub>****Pin 17 — Current-Setting Resistor**

An external resistor to Gnd at this pin sets a reference current that is used to determine the current at the phase/frequency detector outputs PD<sub>Out-Hi</sub> and PD<sub>Out-Lo</sub>. A value of 2 k $\Omega$  is required.

**C<sub>mult</sub>****Pin 21 — Voltage-Multiplier Capacitor**

An external capacitor to Gnd at this pin is used for the on-chip voltage multiplier circuit. The value of this capacitor must be greater than 20 times the value of the largest loop filter capacitor. For example, if the largest loop filter capacitor on either the main loop or the secondary loop is 0.01  $\mu$ F, then a 0.22  $\mu$ F capacitor could be used on the C<sub>mult</sub> pin.

To ensure minimum standby supply current drain, the voltage potential at the C<sub>mult</sub> pin must not be allowed to fall below the potential at the V<sub>pos</sub> pins. Therefore, if the keep-alive oscillator is shut off, the user should tie a large value resistor (> 10 M $\Omega$ ) between the C<sub>mult</sub> pin and V<sub>pos</sub>. This resistor should be sized to overcome leakage from C<sub>mult</sub> to Gnd due to the printed circuit board and the external capacitor. The consequence of not using the resistor is higher supply current drain in standby. If standby is not used, the resistor is not necessary. Also, if the keep-alive oscillator is used, the resistor can be omitted.

**C<sub>reg</sub>****Pin 22 — Regulator Capacitor**

An external capacitor to Gnd at this pin is required for the on-chip voltage regulator. A value of 1  $\mu$ F is recommended.

## 5F. SUPPLY PINS

**DAC V<sub>pos</sub>****Pin 2 — Positive Supply Potential for DACs**

This pin supplies power to both DACs and determines the full-scale output of the DACs. The full-scale output is approximately equal to the voltage at DAC V<sub>pos</sub>. The voltage applied to this pin may be more, less, or equal to the potential applied to the V<sub>pos</sub> pins. The voltage range for DAC V<sub>pos</sub> is 1.8 to 3.6 V with respect to the Gnd pins.

If both DACs are not used, DAC V<sub>pos</sub> should be tied to the same potential as V<sub>pos</sub>.

**V<sub>pos</sub>****Pins 11, 24, 26, and 29 — Principal Positive Supply Potential**

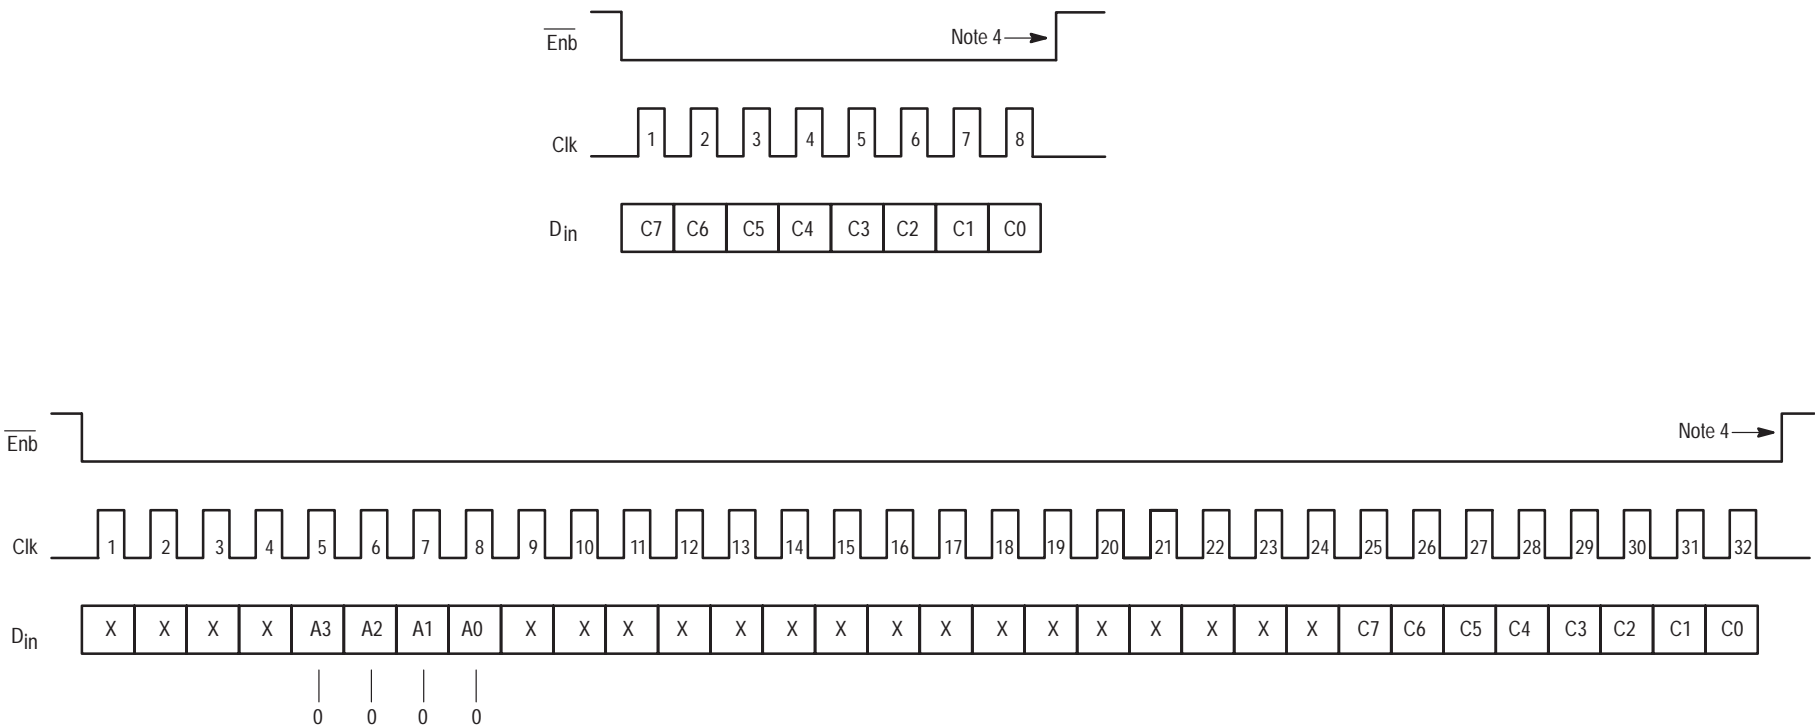

These pins supply power to the main portion of the chip. All V<sub>pos</sub> pins must be at the same voltage potential. The voltage range for V<sub>pos</sub> is 1.8 to 3.6 V with respect to the Gnd pins.

For optimum performance, all V<sub>pos</sub> pins should be tied together and bypassed to a ground plane using a low-inductance capacitor mounted very close to the device. Lead lengths and printed circuit board traces between the capacitor and the IC package should be minimized. (The very-fast switching speed of the device can cause excessive current spikes on the power leads if they are improperly bypassed.)

**Gnd****Pins 14, 15, 18, and 31 — Ground**

Common ground for the device. All Gnd pins must be at the same potential and should be tied to a ground plane.

Figure 13. C Register Access and Formats

**NOTES:**

1. To access the C register, either 8 or 32 clock cycles can be used.
2. For the 8-bit stream, no address bits are needed.
3. For the 32-bit stream, address bits A3 through A0 are required.
4. At this point, the new byte is transferred to the C register. No other register is affected.
5. X signifies a don't care bit.

**C REGISTER BITS**

See Figure 13 for C register access and serial data formats.

**Out A (C7)**

When the Output A pin is selected as a General-Purpose Output (via bits R'21 = R'20 = 0), bit C7 determines the state of the pin. When C7 is 1, Output A is forced to a high level. When C0 is 0 Output A is forced low.

When Output A is not selected as a General-Purpose Output, bit C7 has no function; i.e., C7 is a "don't care" bit.

**Out B/XRef (C6)**

Bit C6 is a dual-purpose bit.

When the Mode pin is tied low, C6 and C1 (PLL Stby), can be used to control Output B. See Table 12. (The reference circuit defaults to crystal configuration.)

When the Mode pin is tied high, additional control of the reference circuit is allowed. See Table 13.

**Table 12. Out B/XRef Bit with Mode Pin = Low**

Bit C6	Bit C1	State of Output B Pin	Condition of Main PLL
0	0	Low level	Active
0*	1*	High impedance*	Standby*
1	0	High level	Active
1	1	High impedance	Standby

\*Power up default.

**Table 13. Out B/XRef Bit with Mode Pin = High**

Bit C6	Reference Configuration
0*	Supports Crystal*
1	Accommodates External Reference

\*Power up default.

**Out C (C5)**

This bit determines the state of the Output C pin. When C5 is 1, Output C is forced to a high-impedance state. When C5 is 0, Output C is forced low.

**PD Float (C4)**

This bit controls the phase detector for the main loop, outputs PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub>. When this bit is 0, the main phase detector operates normally. When the bit is 1, the outputs are forced to the floating state which opens the loop and allows modulation to be introduced into the external VCO input. During this time, the counters are still active. This bit is inhibited from affecting the phase detector during a PD<sub>out-Hi</sub> or PD<sub>out-Lo</sub> pulse.

If the loop is locked prior to C4 being set to 1, the lock detect signal from the main loop continues to indicate "lock" immediately after PD Float is set to 1. If the phase of the loop drifts outside the lock detect window, then the lock detect signal indicates "not locked". If the loop is not locked, and PD Float is set to 1, then the lock detect signal from the main loop continues to indicate "not locked".

**PD' Float (C3)**

This bit controls the phase/frequency detector for the secondary loop, output PD<sub>out'</sub>. When this bit is 0, the secondary phase detector operates normally. When the bit is 1, the output is forced to the floating state which opens the loop and allows modulation to be introduced into the external VCO input. During this time, the counters are still active. This bit is inhibited from affecting the phase detector during a PD<sub>out'</sub> pulse.

If the loop is locked prior to C3 being set to 1, the lock detect signal from the secondary loop continues to indicate "lock" immediately after PD' Float is set to 1. If the phase of the loop drifts outside the lock detect window, then the lock detect signal indicates "not locked". If the loop is not locked, and PD' Float is set to 1, then the lock detect signal from the secondary loop continues to indicate "not locked".

**Osc Stby (C2)**

This bit controls the crystal oscillator and external reference input circuit. When this bit is 0, the circuit is active. When the bit is 1, the circuit is shut down and is in the low-power standby mode. When this circuit is shut down, a keep-alive oscillator for the voltage doubler is activated, unless the doubler is shut off via bits in the R' register. In the crystal oscillator mode, when C2 transitions from a 1 to a 0 state, a kick-start circuit is engaged for a few milliseconds. The kick-start circuit ensures self-starting for a properly-designed crystal oscillator

**NOTE**

Whenever C2 is 1, both bits C1 and C0 must be 1, also.

To minimize standby supply current, the voltage multiplier may be shut down (by bits R'19, R'18, and R'17 being all zeroes). If this is the case and the voltage multiplier feature is being used, the user must allow sufficient time for the phase/frequency detector supply voltage to pump up when the multiplier is brought out of standby. This "pump up" time is dependent on the C<sub>mult</sub> capacitor size. Pump current is approximately 100  $\mu$ A. During the pump up time, either the PLL standby bits C1 and C2 must be 1 or the phase/frequency detector float bits C3 and C4 must be 1.

**PLL Stby (C1)**

When set to 1, this bit places the main PLL in the standby mode for reduced power consumption. PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub> are forced to the floating state, the N and R counters are inhibited from counting, the main loop's input amp is shut off, the Rx current is inhibited, and the main phase/frequency detector is shut off. The reference oscillator circuit is still active and independently controlled by bit C2.

When this bit is programmed to 0, the main PLL is taken out of standby in two steps. First, the input amplifier is activated, all counters are enabled, and the Rx current is no longer inhibited. Any f<sub>R</sub> and f<sub>Y</sub> signals are inhibited from toggling the phase/frequency detectors and lock detector at this time. Second, when the f<sub>R</sub> pulse occurs, the N counter is loaded, and the phase/frequency and lock detectors are initialized via both flip-flops being reset. Immediately after the load, the N and R counters begin counting down together. At this point, the f<sub>R</sub> and f<sub>Y</sub> pulses are enabled to the phase

and lock detectors, and the phase/frequency detector output is enabled to issue an error correction pulse on the next  $f_R$  and  $f_V$  pulses. (Patent issued on this method.)

During standby, data is retained in all registers and any register may be accessed. When setting or clearing the PLL Stby bit, other bits in the C register may be changed simultaneously.

#### PLL' Stby (C0)

When set to 1, this bit places the PLL' section of the chip, which includes the on-chip  $f_{in}'$  input amp, in the standby mode for reduced power consumption.  $PD_{out}'$  is forced to the floating state. The R' and N' counters are inhibited from counting and placed in the low-current mode. The exception is the R' counter's prescaler when the Mode pin is low. The R' counter's prescaler remains active along with the  $f_{out}$  and  $\overline{f_{out}}$  pins when PLL' is placed in standby (Mode pin = low). When the Mode pin is low, the  $f_{out}$  pin,  $\overline{f_{out}}$  pin, and R'

counter's prescaler are shut down only when Osc Stby bit C2 is set to 1.

When C0 is reset to 0, PLL' is taken out of standby in two steps. All PLL' counters and the input amp are enabled. Any  $f_R'$  and  $f_V'$  signals are inhibited from toggling the associated phase/frequency detector at this time. Second, when the  $f_R'$  pulse occurs, the N' counter is loaded and the phase/frequency detector is initialized via both flip-flops being reset. Immediately after the load, the N' and R' counters begin counting down together. At this point, the  $f_R'$  and  $f_V'$  pulses are enabled to the phase and lock detectors, and the phase/frequency detector output is enabled to issue an error correction pulse on the next  $f_R'$  and  $f_V'$  pulses. (Patent issued on this method.)

During standby, data is retained in all registers, and any register may be accessed. When setting or clearing the PLL' Stby bit, other bits in the C register may be changed simultaneously.

Figure 15. N Register Access and Formats

NOTES:

- To access the N register, either 24 or 32 clock cycles can be used.
- For the 24-bit stream, no address bits are needed.
- For the 32-bit stream, address bits A3 through A0 are required.
- At this point, the three new bytes are transferred to the N register. In addition, an Hr to R and Hn' to N' transfer occurs.
- X signifies a don't care bit.

**N REGISTER BITS**

See Figure 15 for N register access and serial data formats.

**Control (N23)**

When the Mode pin is low, Control bit N23 determines the divide ratio of the auxiliary divider which feeds the buffers for the  $f_{out}$  and  $\overline{f_{out}}$  pins. See Table 14 for the overall ratio between  $Osc_e$  and  $f_{out}/\overline{f_{out}}$ .

When the Mode pin is high, N23 must be programmed to 1.

**Table 14.  $Osc_e$  to  $f_{out}$  Frequency Ratio, Mode = Low**

N23	R'1	R'0	$Osc_e$ to $f_{out}$ Frequency Ratio
0	0	0	10:1
0	0	1	12.5:1
0	1	0	12.5:1
0	1	1	12.5:1
1	0	0	8:1
1	0	1	10:1
1	1	0	10:1
1	1	1	10:1

**LD Window (N22)**

Bit N22 determines the lock detect window for the main loop. Refer to Table 15 and Figure 19.

**Table 15. Lock Detect Window**

N22	LD Window (Approximated)
0	32 $Osc_e$ periods
1	128 $Osc_e$ periods

**Phase Detector Program (N21, N20, N19)**

These bits control which phase detector outputs are active for the main loop. These bits also control the timer interval when adapt is utilized for the main loop. See Table 16.

**Table 16. Main Phase Detector Control**

N21	N20	N19	Result
0	0	0	Both PD <sub>out-Hi</sub> and PD <sub>out-Lo</sub> floating
0	0	1	PD <sub>out-Hi</sub> floating, PD <sub>out-Lo</sub> enabled
0	1	0	PD <sub>out-Hi</sub> enabled, PD <sub>out-Lo</sub> floating
0	1	1	Both PD <sub>out-Hi</sub> and PD <sub>out-Lo</sub> enabled
1	0	0	PD <sub>out-Hi</sub> enabled and PD <sub>out-Lo</sub> floating for 16 $f_R$ cycles, then PD <sub>out-Hi</sub> floating and PD <sub>out-Lo</sub> enabled
1	0	1	PD <sub>out-Hi</sub> enabled and PD <sub>out-Lo</sub> floating for 32 $f_R$ cycles, then PD <sub>out-Hi</sub> floating and PD <sub>out-Lo</sub> enabled
1	1	0	PD <sub>out-Hi</sub> enabled and PD <sub>out-Lo</sub> floating for 64 $f_R$ cycles, then PD <sub>out-Hi</sub> floating and PD <sub>out-Lo</sub> enabled
1	1	1	PD <sub>out-Hi</sub> enabled and PD <sub>out-Lo</sub> floating for 128 $f_R$ cycles, then PD <sub>out-Hi</sub> floating and PD <sub>out-Lo</sub> enabled

**Current Ratio (N18)**

This bit allows for MCU control of the PD<sub>out-Hi</sub> to PD<sub>out-Lo</sub> current (or gain) ratio on the main loop phase/frequency detector outputs. See Table 17.

**Table 17. PD<sub>out-Hi</sub> to PD<sub>out-Lo</sub> Current Ratio**

N18	PD <sub>out-Hi</sub> to PD <sub>out-Lo</sub> Current Ratio	PD <sub>out-Hi</sub> Current $C_{mult}$ Pin = 5 V (Nominal)	PD <sub>out-Lo</sub> Current $C_{mult}$ Pin = 5 V (Nominal)
0	4:1	4.4 mA	1.1 mA
1	8:1	4.4 mA	0.55 mA

**N Counter Divide Ratio (N17 to N0)**

These bits control the N Counter divide ratio or loop multiplying factor. The minimum allowed value is 992. The maximum value is 262,143. For ease of programming, binary representation is used. For example, if a divide ratio of 1000 is needed, the 1000 in decimal is converted to binary 00 0000 0011 1110 1000 and is loaded into the device for N17 to N0. See Figure 15.

**R' REGISTER BITS**

See Figure 16 for R' register access and serial data format.

**Y Coefficient (R'23 and R'22)**

These bits are programmed per Table 18. Note that for the MC145181, the bits are always programmed as 00. For compatibility, the other combinations are reserved for use with the MC145225 and MC145230.

**Table 18. Y Coefficient**

R'23	R'22	Maximum Allowed Frequency at $f_{in}$ Pin
0	0	550 MHz
0	1	(not used)
1	0	(not used)
1	1	(not used)

**Output A Function (R'21 and R'20)**

These bits control the function of the Output A pin per Table 19. When selected as a general-purpose output, bit C7 controls the state of the pin. The signals  $f_R$  and  $f_{R'}$  are the outputs of the R and R' counters, respectively. The selection as a detector pulse is a test feature.

**Table 19. Output A Function Selection**

R'21	R'20	Function Selected for Output A
0	0	General-Purpose Output
0	1	$f_R$
1	0	$f_{R'}$
1	1	Phase/Frequency Detector Pulse from either loop

**V-Mult Control (R'19, R'18, R'17)**

These bits control the voltage multiplier per Table 20. When the multiplier is in the active state, the bits determine the voltage multiplier's refresh rate of the capacitor tied to the  $C_{mult}$  pin.

When active, the bits should be programmed for the lowest possible maximum frequency shown in the table. This

ensures that the voltage multiplier is operating at optimum efficiency. For example, for a system utilizing a 16.8 MHz reference, bits R'19, R'18, and R'17 should be programmed as 001 if the user desires to use the voltage multiplier. If the user does not want to use the multiplier, the bits should be programmed as 000. In the latter case, only a 0.1  $\mu$ F bypass capacitor is needed at the  $C_{mult}$  pin and an external phase/frequency detector supply voltage of 3.6 to 5.25 V must be provided to the  $C_{mult}$  pin.

**Table 20. Voltage Multiplier Control**

R'19	R'18	R'17	Multiplier State	Maximum Allowed Frequency at $Osc_e$ Pin
0	0	0	Inactive	80 MHz
0	0	1	Active	20 MHz
0	1	0	Active	40 MHz
0	1	1	Active	80 MHz
1	X	X	—	(for factory evaluation)

**Test/Rst (R'16)**

This bit must be programmed to 0 by the user.

**R' Counter Divide Ratio (R'15 to R'0)**

These bits control the R' counter divide ratio. Thus, these bits determine the secondary loop's minimum step size. This step size is the same as the phase/frequency detector's operating frequency which must not exceed 600 kHz.

With the Mode pin tied high, the minimum allowed value is 20. The maximum value is 32,767.5. For ease of programming, binary representation is used. However, the binary value must be multiplied by 2. For example, if a divide ratio of 1000 is needed, the 1000 in decimal is converted to binary 0000 0011 1110 1000. This value is multiplied by 2 and becomes 0000 0111 1101 0000 and is loaded into the device for R'15 to R'0. See Figure 16.

With the Mode pin tied low, Table 21 shows the divide ratios available. There are two formulas for the divide ratio when Mode is low.

If R'1 R'0 are 00: R' Ratio = (Value of R'15 to R'2)  $\times$  2.

If R'1 R'0 are 01, 10, 11: R' Ratio = (Value of R'15 to R'2)  $\times$  2.5.

Figure 17. Hn' Register Access and Format

**NOTES:**

1. To access the Hn' register (the holding register or first buffer of the double-buffered Hn' and N' combination), 32 clock cycles must be used.
2. Address bits A3 through A0 are required.
3. At this point, the two new bytes are transferred to the Hn' register. Therefore, the N' counter divide ratio is not altered yet and retains the previous ratio loaded. No other register is affected.
4. A transfer from the Hn' (holding) register to the N' register occurs with each N register access.
5. X signifies a don't care bit.
6. The decimal value multiplied by 8 = the hexadecimal value.

Figure 18. D Register Access and Format

NOTES:

1. To access the D Register, 32 clock cycles are used.
2. Address bits A3 through A0 are required.
3. At this point, the two new bytes are transferred to the D register. No other register is affected.
4. Low-power standby state.
5. X signifies a don't care bit.

Figure 19. Lock Detector Operation

**NOTES:**

1. Illustration shown is for the main loop and applies when the secondary loop is either phase locked or in standby. The actual detector outputs for each loop are ANDed together at the LD pin.
2. The secondary loop is similar to the above illustration.
3. The approximate lock detect window for the main loop is either 64 or 256  $Osc_e$  cycles and is programmable via bit N22. The approximate window for the secondary loop is 64  $Osc_e$  cycles and is not programmable.
4. The LD output is low whenever the phase difference is more than the lock detect window.
5. The LD output is high whenever the phase difference is less than the lock detect window and continues to be less than the window for 3  $f_R$  periods or more.

**LOCK DETECTOR OUTPUT CONDITIONS**

$f_R$ versus $f_V$ Relation	Lock Detector Output	Microcontroller Action
Frequency is the same with phase inside the LD window	Static high level output	Senses high level and no edges, therefore loop is locked
Frequency is the same with phase outside the LD window	Static low level output	Senses low level, therefore loop is unlocked
Frequency is slightly different, thus phase is changing	Dynamic "chattering" output, output has transitions	Senses edges, therefore loop is unlocked
Frequency is grossly different	Static low level output	Senses low level, therefore loop is unlocked

**NOTE:** For simplicity, this table applies to the main loop. The secondary loop is similar. The detector outputs feed an AND gate whose output is the LD pin.

Figure 20. PD<sub>Out-Hi</sub> and PD<sub>Out-Lo</sub> Detector Output Characteristics

\*At this point, when both  $f_R$  and  $f_V$  are in phase, the output source and sink circuits are turned on for a short interval.

**NOTES:**

1. The detector generates error pulses during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low-pass filter capacitor.
2. Waveform shown applies when the  $f_{Out}/Pol$  pin is low and the Mode pin is high.
3. When the  $f_{Out}/Pol$  pin is high and Mode is high, the PD<sub>Out-Hi</sub> and PD<sub>Out-Lo</sub> waveform is inverted.
4. The waveform shown is also the default when the Mode pin is low.

Figure 21. PD<sub>Out'</sub> Detector Output Characteristics

\*At this point, when both  $f_{R'}$  and  $f_{V'}$  are in phase, the output source and sink circuits are turned on for a short interval.

**NOTES:**

1. The detector generates error pulses during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low-pass filter capacitor.
2. Waveform shown applies when the  $f_{Out}/Pol'$  pin is low and the Mode pin is high.
3. When the  $f_{Out}/Pol'$  pin is high and Mode is high, the PD<sub>Out'</sub> waveform is inverted.
4. The waveform shown is also the default when the Mode pin is low.

7. APPLICATIONS INFORMATION

7A. CRYSTAL OSCILLATOR CONSIDERATIONS

The oscillator/reference circuit may be connected to operate in either of two configurations. With the Mode pin placed “high” and bit C6 programmed to 1, the oscillator/reference circuit of the MC145181 will accept an external reference input. The external reference signal should be capacitive, connected to Osc<sub>e</sub> with Osc<sub>b</sub> left floating. Commercially available temperature compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide a very stable reference frequency. For additional information about TCXOs and data clock oscillators, please consult the Electronic Engineers Master Catalog, internet web page, or similar publication/service.

The on-chip Colpitts reference oscillator can be selected by either tying the Mode pin low or by programming the C6 bit to zero when Mode is high. The oscillator may be operated in either the fundamental mode, as show by Figure 22, or as an overtone oscillator. The “kick start” feature ensures reduced “stalling” of hard-starting crystals.

Crystal Resonators

The equivalent circuit of a crystal resonator most commonly used is shown in Figure 23. The crystal itself is a specially cut (usually AT for overtone operation) block of quartz. The dimensions, (shape, thickness, length, and width) determine the operating characteristics of the crystal. When deformed and allowed to return naturally to its resting shape, it is observed to oscillate. This oscillation has the typical characteristics of a damped oscillation and an equivalent electrical signal can be found on the surface of the crystal. In addition, if an equivalent electrical signal is applied to the crystal, it will be observed to oscillate. The equivalent values for R<sub>S</sub>, L<sub>S</sub>, C<sub>S</sub>, and C<sub>O</sub> can be used to predict the operation of the crystal when used as an electronic oscillator.

Due to the series/parallel arrangement of the equivalent components, the crystal exhibits two resonances. The first, sometimes just called resonance, is the series resonance of the R<sub>S</sub>, C<sub>S</sub>, L<sub>S</sub> branch. The other, sometimes called the anti-resonance, is the parallel resonance including C<sub>O</sub>. For the series resonance the formula is

$$f_s = \frac{1}{2\pi \sqrt{L_S C_S}}$$

For parallel resonance, the formula is

$$f_p = \frac{1}{2\pi \sqrt{\frac{L_S C_S C_O}{C_O + C_S}}}$$

As can be seen from this equation, the anti-resonant frequency is higher than the series resonant frequency. The ratio between the resonant and anti-resonant frequency can be found using the formula

$$\frac{\Delta f}{f} = \frac{C_S}{2(C_O + C_S)}$$

where

$$\Delta f = |f_s - f_p|$$

and

$$f = \frac{f_s + f_p}{2}$$

By exploiting this characteristic, the crystal oscillator frequency can be tuned slightly. If a capacitor is connected in series with the crystal operating in the resonance mode, the frequency will shift upward. If a capacitance is added in parallel with a crystal operating in an anti-resonant mode, the frequency will be shifted down.

Figure 22. Fundamental Mode Oscillator Circuit

Figure 23. Crystal Resonator Equivalent Circuit

NOTE: Values are supplied by crystal manufacturer (parallel resonant crystal).

Because of the acoustic properties of the crystal resonator, the crystal “tank” responds to energy not only at its fundamental frequency, but also at specific multiples of the fundamental frequency. In the same manner that a shorted or open transmission line responds to multiples of the fundamental frequency, the crystal “tank” responds similarly. A shorted half-wave transmission line (or closed acoustic chamber) will not only resonate at its fundamental frequency, but also at odd multiples of the fundamental. These are called the overtones of the crystal and represent frequencies at which the crystal can be made to oscillate. The equivalent circuit of an overtone crystal is shown in Figure 24.

The components for the appropriate overtone are represented by 1, 3, and 5. The fundamental components are represented by 1, and those of importance for the third and fifth overtones, by 3 and 5.

**Fundamental Mode**

The equivalent circuit for the Colpitts oscillator operating in the fundamental mode is shown in Figure 25.

C3 is selected to provide a small reduction in the inductive property of the crystal. In this manner, the frequency of the oscillator can be “pulled” slightly. The biasing combination of

Figure 24. Overtone Crystal Equivalent Circuit

M1R1 and M2R2 provide the ability to start operation with a higher than normal operating current to stimulate crystal activity. This “kick start” current is nominally four times the normal current. An internal counter times the application of the “kick start” and returns the current to normal after the time out period.

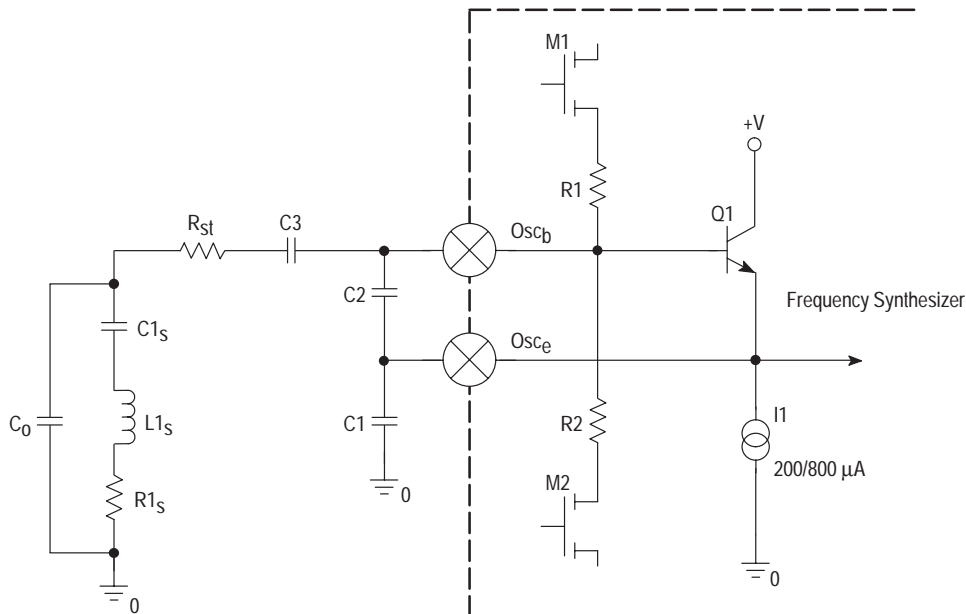

The mutual conductance (transconductance) of the transistor Q1 is useful in determining the conditions necessary for oscillation. The nominal value for the transconductance is found from the formula

$$g_m = \frac{I_e}{26}$$

where  $I_e$  is the emitter current in mA.

The operation of the oscillator can be described using the concept of “negative resistance”. In a normal tuned circuit, any excitation tends to be dissipated by the resistance of the circuit and oscillation dies out. The resistive part of the crystal along with the resistance of the wiring and the internal resistance of C1, C2, and C3, make up this “damping” resistance. Some form of energy must be fed back into the circuit to sustain oscillation. This is the purpose of the amplifier.

Figure 25. Fundamental Mode Colpitts Oscillator Equivalent Circuit

If we define the damping as resistive, we can define the opposite or regenerative property as negative resistance. Figure 26 shows the basic circuit of the Colpitts oscillator. C3 has been combined with the crystal elements for simplicity. For the circuit to oscillate, there must be at least as much "negative resistance" (regeneration) as there is resistance (damping). We can define this by deriving the input impedance for the amplifier.

Figure 26. Colpitts Oscillator Basic Circuit

If a driving signal is defined as  $V_{in}$ , the resultant current that flows can be identified as  $I_{in}$ . The relationship of  $V_{in}$  to  $I_{in}$  is

$$V_{in} = I_{in} (Z_{C1} + Z_{C2}) - I_b (Z_{C2} - \beta Z_{C1})$$

and

$$0 = I_{in} (Z_{C2}) + I_b (Z_{C2} + r_b)$$

where  $I_b$  is the base current of transistor Q1. Solving the two equations and assuming  $Z_{C2} \ll r_b$ , the input impedance can be expressed as

$$Z_{in} \sim \frac{-gm}{\omega^2 C1 C2} + \frac{1}{j\omega \left( \frac{C1 C2}{C1 + C2} \right)}$$

where  $\omega = 2\pi f$ . This is equivalent to the series combination of a real part whose value is

$$REAL = \frac{-gm}{\omega^2 C1 C2}$$

and the imaginary part whose value is

$$IMAG = \frac{1}{j\omega \left( \frac{C1 C2}{C1 + C2} \right)}$$

To sustain oscillation, the amplifier must generate a "negative resistance" equal or greater than the REAL part of the above equation and opposite in polarity.

$$R_{neg} = \frac{-gm}{\omega^2 C1 C2}$$

As long as the relation

$$-R_{neg} = -SUM (R_s + R_{st} + R_{C1} + R_{C2} + R_{C3}) ,$$

the circuit will oscillate and the frequency of oscillation will be defined as

$$f_o = \frac{1}{2\pi\sqrt{L_s (C1 \parallel C2 \parallel C3)}}$$

where C3 is the series frequency adjusting capacitor.

In determining values for C1, C2, and C3, two limits are considered. At one end is the relationship of C3 to C2 and C1. If C3 is made 0 or the reactance of C3 is small compared to the reactance of C1 and C2, no adjustment of the crystal frequency is possible. The other limit is the relationship

$$gm Z_{C1} Z_{C2} > R_{sum}$$

where  $R_{sum}$  is the sum of resistances in the resonant loop. Since this equation must be true for the circuit to oscillate, it is obvious that as the values of C1 and C2 are increased, the series resistances must be reduced and/or gm increased. Since gm is a function of device current and there is a physical limit on how small  $R_{sum}$  can be made, at some point oscillation can no longer be sustained.

Normally, it is desirable to choose the "negative resistance" to be several times greater than the "damping" resistance to ensure stable operation. A factor of four or five is a good "rule of thumb" choice.

To determine crystal power, the equivalent circuit shown in Figure 27 can be used. In this case, we are addressing a condition where the transistor amplifier is operating at the limit of class A; that is, the device is just at cutoff during the peak negative excursions. At this point,

$$R_e = gm X_{C1} X_{C2}$$

if the amplitude is constant and the oscillator is stable. For this to occur, the sum of all resistances in the resonant loop will be equal to  $R_e$ , where  $R_e$  represents the effective resistance of  $I_1$ . This can be written as

$$R_{sum} = R_s + R_{st} = R_e$$

where  $R_s$  is the crystal resistance and  $R_{st}$  is the additional distributed resistances within the resonant loop. At the point where the transistor enters cutoff we have the equation

$$-I_{in} = \frac{v1 + v2}{X_{Is} + R_e} = \frac{(I_{in} - I_b) Z_{C2} + (I_{in} + \beta I_b) Z_{C1}}{X_{Is} + R_e}$$

$\beta$  = current gain of the transistor. Rewriting:

$$I_{in} = \frac{I_b (Z_{C2} - \beta Z_{C1})}{Z_{C1} + Z_{C2} + X_{Is} + R_e}$$

For oscillation to occur, we must have

$$Z_{C1} + Z_{C2} + X_{Is} \sim 0 .$$

If we assume  $\beta Z_{C1}$  is normally much greater than  $Z_{C2}$  then

$$I_{in} \sim \frac{-I_e Z_{C1}}{R_e}$$

For the condition we have specified,

$$I_e(\text{bias}) + I_e(\text{instantaneous ac}) = 0$$

the transistor is just cutting off and the peak current,  $I_{in}$  is equal to the bias current. The peak input current is represented as

$$I_{in}(\text{peak}) = \frac{I_e |Z_{C1}|}{R_e}$$

The power dissipation of the series resistances in the resonant loop can be written as

$$P = \frac{I_{in}(\text{peak})^2 R}{2} = \frac{(I_e |Z_{C1}|)^2}{2 R_{sum}}$$

where  $R_{sum} = R_e$ .

The power dissipation for the crystal itself becomes

$$P_{crystal} = \frac{(I_e |Z_{C1}|)^2}{2 R_s}$$

Figure 27. Equivalent Circuit for Crystal Power Estimation

**Overtone Operation**

For overtone operation, the circuit is modified by the addition of an inductor, L1; and a series capacitor, C4. C4 is inserted as a dc blocking capacitor whose capacitance is chosen sufficiently large so that its reactance can be ignored. This circuit is shown in Figure 28.

For oscillation to occur at the overtone frequency, the condition

$$gm Z_{C1} Z_{C2} > R_s$$

must exist.

$Z_{C1}$  represents the impedance across C1 and can be defined as

$$Z_{C1} = jX_{C1} || (R_{l1} + jX_{l1})$$

where  $R_{l1}$  is the dc resistance of the inductor L1.

For overtone operation, this must occur at the desired harmonic. For example, if the crystal is chosen to oscillate at the third overtone, C1 and C2 must be chosen so that the above condition exists for  $Z_{C1}$  and  $Z_{C2}$  at the third harmonic of the fundamental frequency for the crystal. In addition, care must be taken that the “negative resistance” of the amplifier is not sufficient at the fundamental frequency to induce oscillation at the fundamental frequency. It may be necessary to add additional filtering to reduce the gain of the amplifier at the fundamental frequency. The key to achieving stable overtone oscillator operation is ensuring the existence of the above condition at the desired overtone while ensuring its failure at all other frequencies.

L1 and C1 are chosen so that

$$\frac{1}{2\pi \sqrt{L_1 C_1}} > F_f$$

where  $F_f$  is the fundamental frequency of the crystal resonator. If L1 and C1 are chosen to be net capacitive at the desired overtone frequency and if the condition

$$gm Z_{C1} Z_{C2} > R_s$$

is true only at the desired overtone frequency, the oscillator will oscillate at the frequency of the overtone. Normally, L1 and C1 are not chosen to be resonant at the overtone frequency but at a lower frequency to ensure that the parallel

combination of L1 and C1 is capacitive at the overtone frequency and inductive at the fundamental frequency.

$$F_f < \frac{1}{2\pi \sqrt{L_1 C_1}} < F_o$$

The net inductance of the rest of the resonant loop then balances this capacitance at the overtone frequency.

$$\frac{1}{\frac{1}{X_{l1} - X_{C3}} - \frac{1}{X_{C0}}} + X_{l2} + X_{l(\text{stray})} - X_{C3} + \frac{1}{\frac{1}{X_{l1}} - \frac{1}{X_{C1}}} = 0$$

L2 and C3 are chosen to provide the desired adjustment to the resonant overtone frequency. This is normally computed by calculating the expected ppm change at the resonant frequency and using this to define the value of the reactance necessary to produce this change.

$$\Delta F_f (\text{ppm}) = \frac{X (\text{of } L_2 \text{ and } C_3)}{Z (\text{crystal at resonance})}$$

$$\Delta F_f (\text{ppm}) = X(\text{of } L_2 \text{ and } C_3)/Z(\text{crystal at resonance})$$

The values needed for this calculation can be derived from the value of the fundamental frequency and  $C_0$ . If  $C_0$  is known or can be measured,  $C_s$  is defined as

$$C_s = \frac{C_0}{200}$$

for an AT cut crystal.

The fundamental frequency can be used to calculate the value for  $L_s$  using either the series resonant or parallel resonant formulas given earlier. Since the Q of the crystal,

$$Q = \frac{X}{R}$$

is usually sufficiently large at the resonant frequency so that

$$R_s \ll Z(\text{crystal})$$

# MC145181

$R_S$  can be ignored. The value for  $C_3$  and  $L_2$  are chosen so that

$$X_{C3} = X_{L2}$$

when  $C_3$  is adjusted to approximately half its maximum capacitance. At this setting, the combination produces a zero change in the overtone frequency. If  $C_3$  is then chosen so that  $X_{C3}$  at minimum capacitance is

$$[X_{C3(\max)}] - X_{L2} \geq \Delta F_f (\text{ppm}) Z(\text{crystal})$$

and  $L_2$  is approximately

$$X_{L2} = \frac{X_{C3(\max)}}{2}$$

then

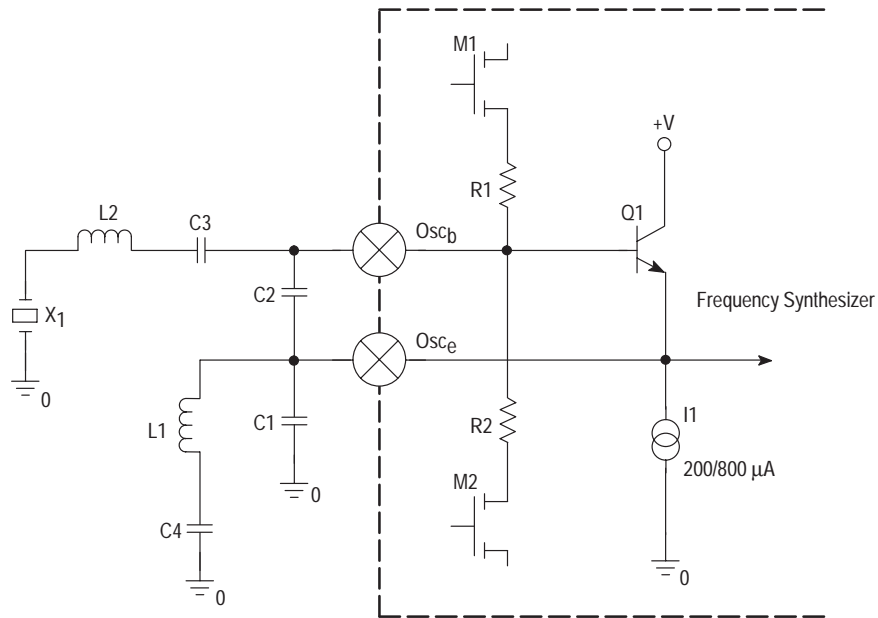

$$X_{C3(\max)} \geq 2[\Delta F_f (\text{ppm})] Z(\text{crystal})$$

and

$$X_{C3(\min)} = \frac{X_{C3(\max)}}{4}$$

This results in an adjustable change in the operating frequency of  $+\Delta F_f (\text{ppm})$  and  $-\Delta F_f (\text{ppm})/2$ . If ratios nearer to 1:1 are used for  $X_{C3(\max)}$  and  $X_{L2}$ , the tuning range will be skewed with a wider  $-\Delta F_f (\text{ppm})$  but at the expense of less adjustability over the  $+\Delta F_f (\text{ppm})$  range.

Figure 28. Colpitts Oscillator Configured for Overtone Operation

**7B. MAIN LOOP FILTER DESIGN — CONVENTIONAL**

The current output of the charge pump allows the loop filter to be realized without the need of any active components. The preferred topology for the filter is illustrated in Figure 29.

The  $R_O/C_O$  components realize the primary loop filter.  $C_a$  is added to the loop filter to provide for reference sideband suppression. If additional suppression is needed, the  $R_x/C_x$  realizes an additional filter. In most applications, this will not be necessary. If all components are used, this results in a fourth order PLL, which makes analysis difficult. To simplify this, the loop design will be treated as a second order loop ( $R_O/C_O$ ), and additional guidelines are provided to minimize the influence of the other components. If more rigorous analysis is needed, mathematical/system simulation tools should be used.

Component	Guideline
$C_a$	$<0.1 \times C_O$
$R_x$	$>10 \times R_O$
$C_x$	$<0.1 \times C_O$

The focus of the design effort is to determine what the loop's natural frequency,  $\omega_O$ , should be. This is determined by  $R_O$ ,  $C_O$ ,  $K_P$ ,  $K_V$ , and  $N_t$ . Because  $K_P$ ,  $K_V$ , and  $N_t$  are given, it is only necessary to calculate values for  $R_O$  and  $C_O$ . There are three considerations in selecting the loop bandwidth:

1. Maximum loop bandwidth for minimum tuning speed.
2. Optimum loop bandwidth for best phase noise performance.
3. Minimum loop bandwidth for greatest reference sideband suppression.

Usually a compromise is struck between these three cases, however, for a fixed frequency application, minimizing the tuning speed is not a critical parameter.

To specify the loop bandwidth for optimal phase noise performance, an understanding of the sources of phase noise in the system and the effect of the loop filter on them is required. There are three major sources of phase noise in the phase-locked loop — the crystal reference, the VCO, and

the loop contribution. The loop filter acts as a low-pass filter to the crystal reference and the loop contribution. The loop filter acts as a high-pass filter to the VCO with an in-band gain equal to unity. The loop contribution includes the PLL IC, as well as noise in the system; supply noise, switching noise, etc. For this example, a loop contribution of 15 dB has been selected.

The crystal reference and the VCO are characterized as high-order  $1/f$  noise sources. Graphical analysis is used to determine the optimum loop bandwidth. It is necessary to have noise plots from the manufacturers of both devices. This method provides a straightforward approximation suitable for quickly estimating the optimal bandwidth. The loop contribution is characterized as white-noise or low-order  $1/f$  noise, given in the form of a noise factor which combines all the noise effects into a single value. The phase noise of the crystal reference is increased by the noise factor of the PLL IC and related circuitry. It is further increased by the total divide-by- $N$  ratio of the loop. This is illustrated in Figure 30. The point at which the VCO phase noise crosses the amplified phase noise of the crystal reference is the point of the optimum loop bandwidth. In the example of Figure 30, the optimum bandwidth is approximately 15 kHz.

To simplify analysis further, a damping factor of 1 will be selected. The normalized closed loop response is illustrated in Figure 31 where the loop bandwidth is 2.5 times the loop natural frequency (the loop natural frequency is the frequency at which the loop would oscillate if it were unstable). Therefore, the optimum loop bandwidth is  $15 \text{ kHz}/2.5$  or 6.0 kHz (37.7 krads) with a damping coefficient,  $\zeta \sim 1$ .  $T(s)$  is the transfer function of the loop filter.

where

$$N_t = \text{Total PLL Divide Ratio} - 8 \times N$$

where ( $N = 25 \dots 40$ ),

$$K_V = \text{VCO Gain} - 2\pi \text{ Hz/V},$$

$$K_P = \text{Phase Detector/Charge Pump Gain} - A$$

$$= (|I_{OH}| + |I_{OL}|) / 4\pi.$$

Technically,  $K_V$  and  $K_P$  should be expressed in radian units [ $K_V$  (rad/V),  $K_P$  (A/rad)]. Since the component design equation contains the  $K_V \times K_P$  term, the  $2\pi$  cancels and the value can be expressed as AHz/V (amp hertz per volt).

**Figure 29. Loop Filter**

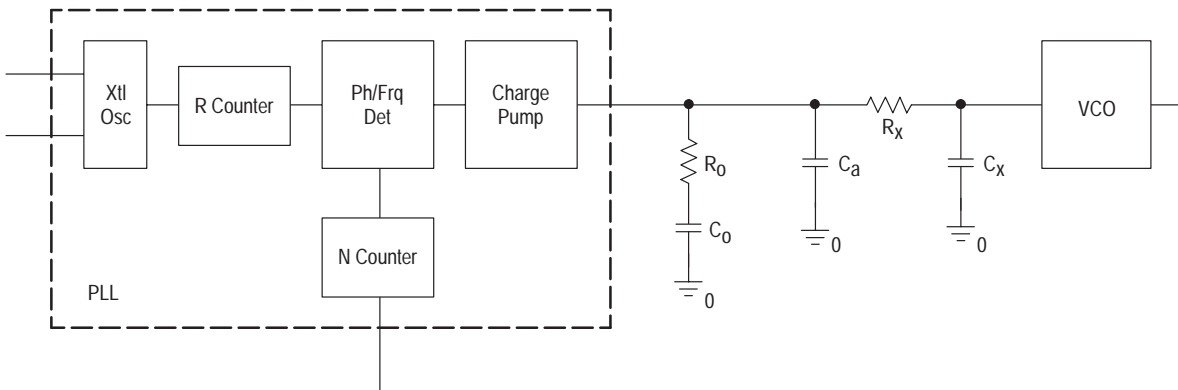

Figure 30. Graphical Analysis of Optimum Bandwidth

In summary, follow the steps given below:

- Step 1: Plot the phase noise of crystal reference and the VCO on the same graph.
- Step 2: Increase the phase noise of the crystal reference by the noise contribution of the loop.
- Step 3: Convert the divide-by-N to dB ( $20 \log 8 \times N$ ) and increase the phase noise of the crystal reference by that amount.
- Step 4: The point at which the VCO phase noise crosses the amplified phase noise of the crystal reference is the point of the optimum loop bandwidth. This is approximately 15 kHz in Figure 30.
- Step 5: Correlate this loop bandwidth to the loop natural frequency per Figure 31. In this case the 3.0 dB bandwidth for a damping coefficient of 1 is 2.5 times the loop's natural frequency. The relationship between the 3.0 dB loop bandwidth and the loop's "natural" frequency will vary for different values of  $\zeta$ . Making use of the equations defined in Figure 32, a math tool or spread sheet is useful to select the values for  $R_0$  and  $C_0$ .

#### Appendix: Derivation of Loop Filter Transfer Function

The purpose of the loop filter is to convert the current from the phase detector to a tuning voltage for the VCO. The total transfer function is derived in two steps.

Step 1 is to find the voltage generated by the impedance of the loop filter.

Step 2 is to find the transfer function from the input of the loop filter to its output. The "voltage" times the "transfer function" is the overall transfer function of the loop filter. To use these equations in determining the overall transfer function of a PLL, multiply the filter's impedance by the gain constant of the phase detector, then multiply that by the filter's transfer function. Figure 33 contains the transfer function equations for the second, third, and fourth order PLL filters.

#### PSpice Simulation

The use of PSpice or similar circuit simulation programs can significantly reduce laboratory time when refining a PLL

Figure 31. Closed Loop Frequency Response for  $\zeta = 1$ 

design. The following describes the use of behavioral modeling to develop useful models for studying loop filter performance. In many applications the levels of sideband spurs can also be studied.

Behavioral modeling is chosen, as opposed to discrete device modeling, to improve performance and reduce simulation time. PLL devices can contain several thousand individual transistors. To simulate at this level can result in generation of an enormous amount of data when compared to a simpler behavioral model. For example, a logic NAND gate can contain several transistors. Each of these requires a data set for each of the transistor terminals. If a half dozen transistors are used in the gate design, both current and voltage measurements for each terminal of each device for every node in the circuit is calculated. The gate can be expressed as a behavioral model, which is treated and simulated as a single device. Since PSpice sees this as a single rather than multiple devices, the amount of accumulated data is much less, resulting in a faster simulation.

For applications using integrated circuits such as PLLs, it is desirable to investigate the performance of the circuitry added externally to the integrated circuit. By using behavioral modeling rather than discrete device modeling to represent the integrated circuit, the engineer is able to study the performance of the design without the overhead contributed by simulating the integrated circuit.

#### Phase Frequency Detector Model

The model for the phase frequency detector is derived using the waveforms shown in Figure 20. Two signals are present at the input of the phase frequency detector. These are the reference input and the feedback from the VCO and/or prescaler. The two signals are compared to determine the lag/lead relationship between the two signals and pulses generated to represent the leading edge of each signal. A pulse whose width equals the lead of one input signal over the other is generated by an RS flip-flop (RSFF). One RSFF generates a pulse whose width equals the lead of the reference signal over the feedback signal, and a second RSFF generates a signal whose width is the lead of the feedback signal over the reference signal. The logical model for the phase frequency detector is shown in Figure 34.

Figure 32. Design Equations for the Second Order System

$$T(s) = \frac{R_0 C_0 s + 1}{\left(\frac{N C_0}{K_p K_V}\right) s^2 + R_0 C_0 s + 1} = \frac{\left(\frac{2\zeta}{\omega_0}\right) s + 1}{\left(\frac{1}{\omega_0^2}\right) s^2 + \left(\frac{2\zeta}{\omega_0}\right) s + 1}$$

$$\left(\frac{N C_0}{K_p K_V}\right) = \left(\frac{1}{\omega_0^2}\right) \rightarrow \omega_0 = \sqrt{\frac{K_p K_V}{N C_0}} \rightarrow C_0 = \left(\frac{K_p K_V}{N \omega_0^2}\right)$$

$$R_0 C_0 = \left(\frac{2\zeta}{\omega_0}\right) \rightarrow \zeta = \left(\frac{\omega_0 R_0 C_0}{2}\right) \rightarrow R_0 = \left(\frac{2\zeta}{\omega_0 C_0}\right)$$

$$Z_{LF}(s) = \frac{R_0 C_0 s + 1}{C_0 s}$$

$$T_{LF}(s) = \frac{V_t(s)}{V_p(s)} = 1, \quad V_p(s) = K_p(s) Z_{LF}(s)$$

$$Z_{LF}(s) = \frac{R_0 C_0 s + 1}{C_0 R_0 C_a s^2 + (C_0 + C_a) s}$$

$$T_{LF}(s) = \frac{V_t(s)}{V_p(s)} = 1, \quad V_p(s) = K_p(s) Z_{LF}(s)$$

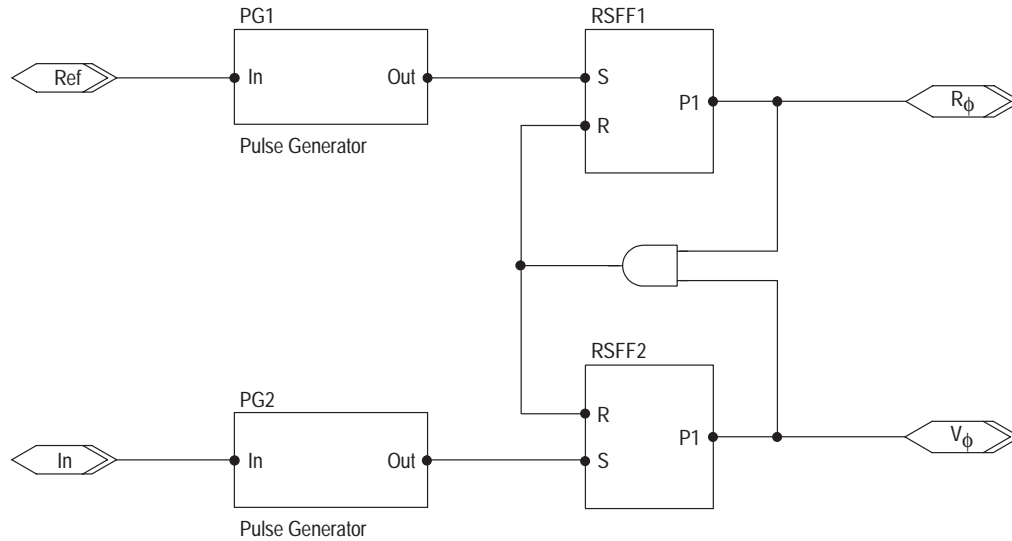

$$Z_{LF}(s) = \frac{(R_0 C_0 s + 1) (R_x C_x s + 1)}{C_0 R_0 C_a R_x C_x s^3 + [(C_0 + C_a) R_x C_x + C_0 R_0 (C_x + C_a)] s^2 + (C_0 + C_a + C_x) s}$$

$$T_{LF}(s) = \frac{V_t(s)}{V_p(s)} = \frac{1}{(R_x C_x s + 1)}, \quad V_p(s) = K_p(s) Z_{LF}(s)$$

Figure 34. Phase Frequency Detector Logic Diagram

The behavioral model of the phase frequency detector shown in Figure 35 is derived using the phase frequency detector logic diagram. Behavioral models for the pulse generator, AND gate (Figure 36), and RS flip-flops (Figure 37) are created using analog behavioral blocks. The pulse generator is created using a delay block and a “gate” defined by the behavioral expression:

$$\text{If } [V(v1) \geq 1 \ \& \ V(v2) \ , \ 1, 5, 0]$$

v1 and v2 represent the two inputs to the block.

This is the behavioral expression for an AND gate with one input inverted. The addition of the delay element produces a pulse whose width equals the delay element.

The pulses appearing at the output of HB1 and HB2 (Figure 35) are used to set the flip-flops, RSFF1, and RSFF2. The leading pulse will set the appropriate flip-flop resulting in a high at the output of that flip-flop. The output of this flip-flop will remain high until the arrival of the second (or lagging) pulse sets the second RS flip-flop. The presence of a high on both RS flip-flop outputs results in the generation of the reset pulse. The reset pulse is generated by the analog behavioral block (configured as an AND gate) and the delay element. The delay element is necessary to eliminate the zero delay paradox of input to output to input.

The output of the phase frequency detector is two pulse trains appearing at  $R_\phi$  and  $V_\phi$ . When the PLL is locked, the pulses in both pulse trains will be of minimum width. When the phase frequency detector is out of lock, one pulse train will consist of pulses of minimum width while the width of the pulses in the second train will be equal to the lead/lag relationship of the input signals. If the Ref input leads ‘In’, the pulse train at  $R_\phi$  will consist of pulses whose width equals the lead of Ref. If Ref lags ‘In’, the width of the pulses appearing at  $V_\phi$  will equal this lag.

The terms lead and lag used in this explanation represent an occurrence in time rather than a phase relationship. At any condition other than locked, one input (either In or Ref), will be of a higher frequency. This results in the arrival of the pulse at that input ahead of the pulse at the other input, or leading. The second then is lagging.

To simulate the operation of the phase frequency detector in an actual circuit, a charge pump needs to be added. The behavioral model for this is shown in Figure 38. Two voltage-to-current behavioral models are used to produce the charge pump output. Two voltage-controlled switches with additional behavioral models, monitor the voltage of the output of the charge pump and clamp to 0 or  $V_{CC}$  to simulate a real circuit.

To ensure the model conforms to the PLL, the delay blocks in the phase frequency detector should be set to the expected value as specified by the MC145181 data sheet. In addition, the charge pump sink and source current behavioral model should also be set to deliver the desired current and  $V_{CC}$  specified to ensure correct clamping.

### Modeling the VCO

The VCO (Figure 39) is also modeled using Analog Behavioral Modeling (ABM). The model used in the following examples assumes a linear response; however, the control voltage equation can be modified as desired. The circuit is modeled as a sine generator controlled by the control voltage. The sine generator can be modeled using the EVALUE function or the ABM function. In Figure 39, the EVALUE function is used to generate the divided output and the ABM function is used for the undivided output. Either the GVALUE or the ABM/I function can be used for the control voltage.

Figure 35. Behavioral Model of the Phase Frequency Detector

Figure 36. Behavioral Block Used for the Pulse Generator

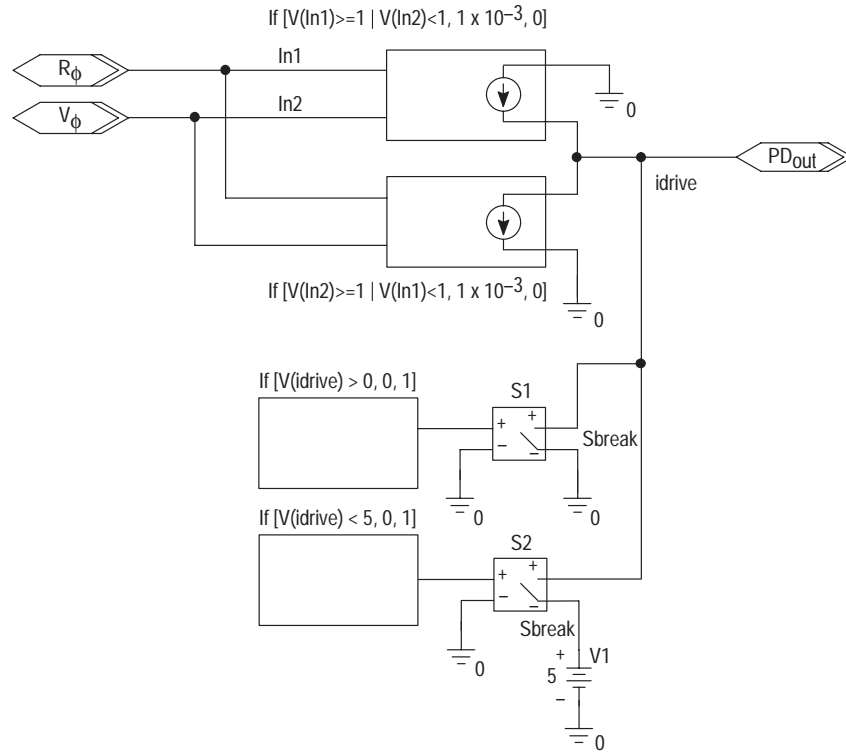

Figure 37. Behavioral Block Used as an RS Flip-flop

# MC145181

**Figure 38. Charge Pump Model**

**Figure 39. VCO Behavioral Model**

The equation for the sine generator is:

$$e = \sin \left[ t_w \frac{f_c}{N} \text{ time} + v(\text{int}) \right]$$

$f_c$  is defined as the output frequency when the control voltage is 0. This is the expected VCO frequency before frequency division. For the purpose of simulation, the counter value,  $N$ , has been written into the equation to ensure the correlation between the modeled circuit and the mathematical loop filter calculations.  $t_w$  is  $2\pi$ ; additional decimal places can be added as needed.  $v(\text{int})$  is the control voltage effect and is defined in these examples as:

$$v(\text{int}) = \frac{k_1}{t_w N} v(\text{cntl}) \times 10^{-6}$$

where  $k_1$  is the VCO gain in rad/V.

The value  $C_1$  in the schematic of the VCO can be arbitrarily changed; however, the value must match that of  $Q_C$ .  $Q_C$  determines the value of the current to be integrated by the capacitor  $C_1$ .  $R_1$  is arbitrarily set to  $1 \times 10^{99}$  and is not an active part of the circuit; however, it must be included to prevent open pin errors from the PSpice software. The GVALUE function is used to perform the generation of  $v(\text{int})$ . There is some interaction between the integrator, (GVALUE output and  $C_1$ ) and  $R_1$ .  $V(\text{int})$  is a continuous ramp that is loaded by the resistance of  $R_1$ . Unless the GVALUE output current is sufficiently large for the value chosen for  $R_1$ , the VCO control voltage required to maintain lock will increase throughout the simulation producing nonlinear operation. Modifications to the circuit can be performed either by changing the values in the parameter list or for major changes to the VCO characteristics, the equations for the sine generator, or control voltage can be altered.

The output of the sine generator is amplified by 1000 to produce a sharp rise/fall time and the output limited to swing between the values of 0 V and 5 V to convert it to a digital output. The resultant circuit/symbol accepts a voltage input from the loop filter and produces a square wave output at the

desired frequency. This frequency should be chosen to represent the frequency present at the output of the  $N$  counter of the PLL frequency synthesizer.

The second output represented by the ABM function is a sine wave output of the frequency expected from the actual VCO. The primary purpose of this output is to allow full frequency simulation for spectrum analysis. By running a transient analysis of sufficient time, it is possible to determine spur content and level. If sufficient resolution is used in the simulation, the PSpice probe FFT transform can be used to provide the typical spectrum analyzer display.

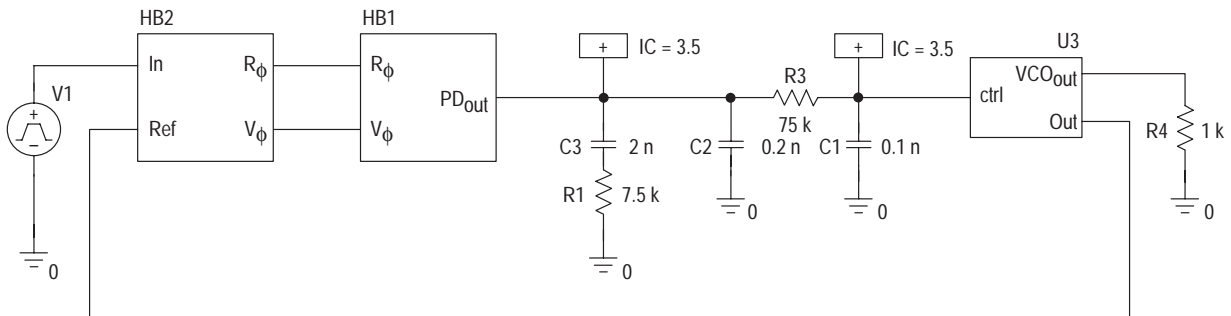

**Loop Filter Simulation**

The circuit shown in Figure 40 is used to simulate the closed loop operation for a single charge pump output. Component values for the loop filter should be computed using information from the previous section. Initial conditions can be set using the "IC1" symbol with starting values specifying the initial condition.

By adjusting component values for the loop filter, performance of the closed loop operation can be monitored. The control voltage to the input of the VCO can be monitored for a variety of conditions including settling time, lock time, and ripple present at the VCO input. In addition, the output of the VCO can be monitored for spur sidebands caused by ripple on the loop filter output; however, expected operation at high frequencies may be difficult due to the excessive data that can be generated.

As the divider ratio,  $N$ , increases for a fixed step frequency, the number of data points required to obtain sufficient information to overcome aliasing problems may become excessively large. In addition, the number of samples required should be three or more per cycle. For VCO frequencies in the range of 500 MHz, this means the step ceiling needs to be in the range of 100 to 500 ps. If a simulation time of 1 ms is needed, the actual computer time can be several hours with data accumulation in the 1– to 2–Gbyte range.

**Figure 40. PLL Closed Loop Model**

7C. MAIN LOOP FILTER DESIGN — ADAPT

Introduction

For PSpice simulation, the schematic model shown in Figure 41 was chosen. The classical PLL model employing a phase-frequency detector, a VCO, and an adaptive loop filter is used to simplify visualization of circuit operation. The parameter tables allow for modification of circuit performance by providing an easy method for altering critical values without necessitating changes to sub-level schematics. The definition for the terms are:

- $t_w = 2\pi$ ,
- $f_r$  = reference frequency,
- $t_d$  = time delay; allows delay of the start of the high current mode (used to perform reference spur measurements),
- CPL = charge pump low current,
- CPH = charge pump high current,
- N = N counter value,

$S_z$  = amount the N counter is being increased (or decreased) by,

$S_t$  = number of  $f_r$  cycles that CPH is active; this value is either 16, 32, 64, or 128,

VCPHH = charge pump voltage – high,

VCPHL = charge pump voltage – low,

K1 = VCO gain (Hz/volt),

$f_c$  = VCO frequency at 0 V control voltage,

H = reference spur scaling factor.

Modeling the Phase-frequency Detector

Figure 42 is a schematic of the phase-frequency detector. It includes the reference oscillator model, phase-frequency detector model, and charge pump models. V1 is the control element used to generate the step time for switching between CPL and CPH. The signal source VPULSE, is used to simulate the timer that controls when CPL and CPH are turned on. PW calculates the pulse width that simulates the counter from the values for  $S_t$  and  $f_r$  that are entered in the parameter tables on the top level schematic.

Figure 41. Top Level PLL Model

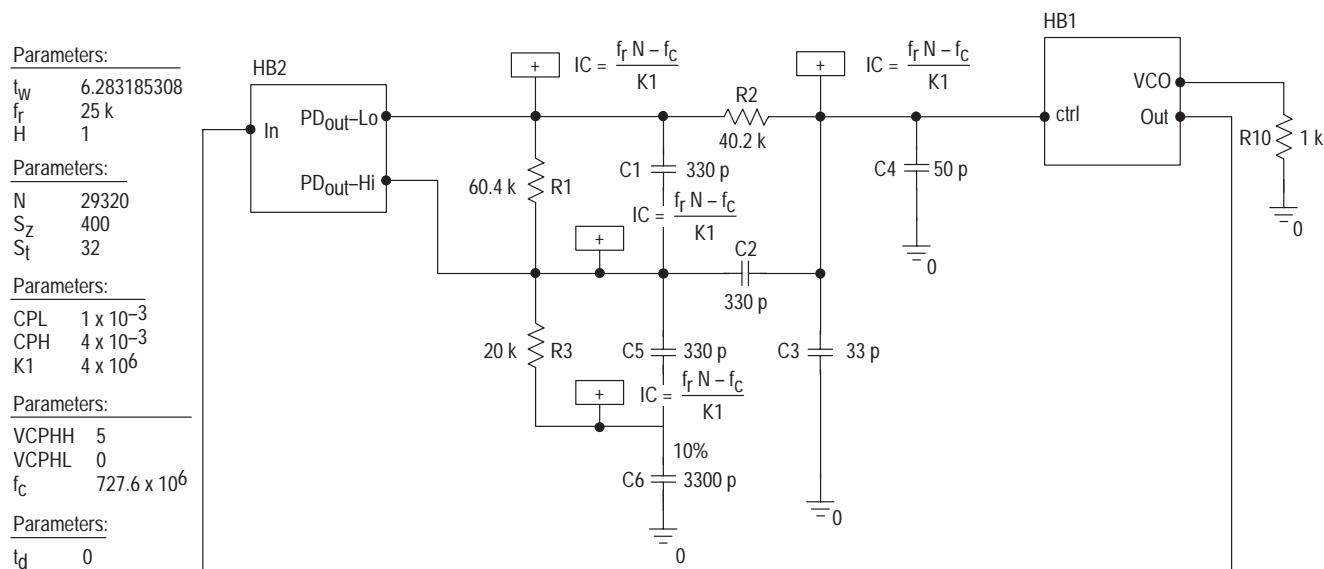

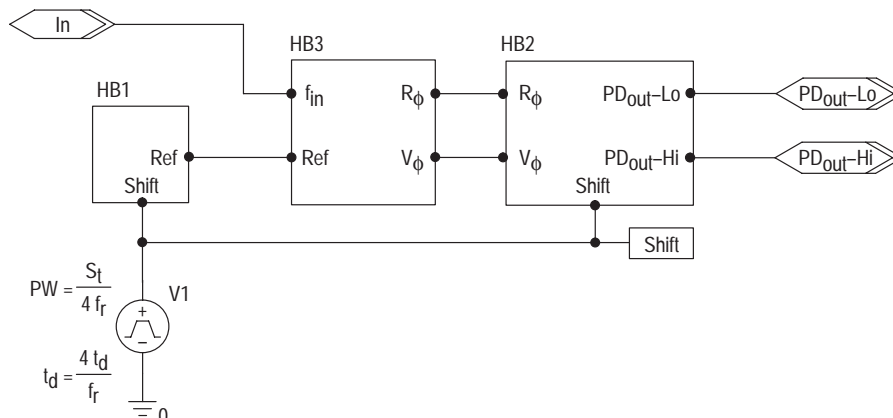

Figure 42. Phase-frequency Detector with Dual Charge Pumps

**Reference Oscillator**

The reference oscillator is shown in Figure 43. The oscillator is modeled using an analog behavioral block. The function for the block is written as an “If” condition. If the signal shift is low, the reference frequency  $f_r$  will be generated if shift is high, a signal of four times  $f_r$  will be generated. The limiter/gain block converts the low level sine wave output of the analog behavioral block into a square wave. The values of 0 for the low value and 5 for the high value are used throughout. These values are chosen out of habit and are not critical in an analog behavioral environment, providing the conformity is universal throughout the design.

**Figure 43. Reference Oscillator**

**Phase–frequency Detector**

The actual phase–frequency detector model minus reference oscillator and charge pumps is shown in Figure 44. The detector is composed of three delay modules: a behavioral AND gate, and two RS flip–flops. The STP function resets the phase/frequency detector logic on initiation of the simulator. The circuit for the behavioral RS flip–flop is shown in Figure 45.

The RS flip–flop equation illustrates the benefit of using the behavioral block instead of using a primitive logic element. A delay block and the behavioral gate equation generate a pulse whose width is equal to the value of the delay block. To generate the output using a primitive logic element such as a NAND gate, an inverter would be necessary to invert one of the NAND inputs. This approach requires three elements to be used instead of the two of the behavioral approach just for the pulse generator. In the behavioral approach, the equation for the behavioral AND gate is folded into the RS flip–flop, eliminating a separate gate altogether. Constructing the model with classic logic elements would require two NOR gates for the flip–flop, a delay element, an inverter, and an AND gate; five elements as compared with three for the behavioral approach. Since the RS flip–flop is used in two places in the model, four less components are needed for simulation. Since the speed of the simulation is directly impacted by the number of components being simulated, any reduction in the total number of components is a savings in simulation time and computer memory.

The RS flip–flops generate the lead or lag outputs that are used to “steer” the VCO. The pulse generator equation produces narrow pulses coincident with the leading edge of each of the input signals. These pulses set the appropriate RS flip–flop. Once set, the leading flip–flop must wait until the lagging flip–flop is also set. The behavioral AND gate provides the necessary output pulse to reset the flip–flops. The delay element placed at the output of the behavioral AND gate prevents an undefined state for the detector. The value 5 ns is chosen to correspond with the data sheet. The logic functions as a three state phase/frequency detector with an operating range of  $\pm 2\pi$ .  $R_\phi$  and  $V_\phi$  deliver positive pulses, whose width represents the amount of the lead of each input over the other input.

**Figure 44. Phase–frequency Detector Logic**

Figure 45. Behavioral RS Flip-flop

### Charge Pump Model

The schematic used for the charge pump in the phase-frequency detector model is shown in Figure 46. Each charge pump is made from two analog behavioral blocks. The blocks chosen are three input behavioral blocks with current outputs. The two blocks are connected in push-pull to generate the appropriate source and sink output. The output of each block is defined using an “If” statement to monitor the input signals and generate the correct output at the appropriate time.

One note about this type of design. SPICE does not limit the output voltage swing necessary to generate the programmed current. It is possible to implement values for the loop filter, which will cause the charge pump to exceed the rail voltage. To limit the output voltage to prevent exceeding the value of the rails, the two behavioral blocks, voltage-controlled switches S1 and S2, and constants VCPHH and VCPHL are added. S1 and S2 on/off resistance is set to 1  $\Omega$  and 1  $\times 10^{12}$   $\Omega$ , and the off/on voltage is set to 0 V and 1 V to correspond to the behavioral blocks. The values defined by the constants are accessible from the parameter tables on the top level schematic.

### VCO Model

The model used for simulating the VCO is shown in Figure 47. The VCO is composed of a sine wave generator and a control element. An analog behavioral block is used as a sine wave generator and a GVALUE element is used as a control element. The GVALUE is operated as an integrator. The output of the integrator is defined as

$$v(\text{int}) = k_1 v(\text{ctrl}) Q_C$$

The block designated to provide the feedback to the phase-frequency detector uses a single input analog behavioral block. The signal shift generated by V1 in the phase-frequency detector block is used to define the output frequency of the behavioral block. In this manner, the switching of the N and R values for the programmable counters can be simulated. In the implementation shown, the two frequencies will be either 25 kHz or 100 kHz when locked to the reference oscillator.

The other behavioral block is used to generate a VCO output dependent on the loop, but not contributing to the operation of the loop. This is used to emulate the actual VCO output with one modification. “H” has been added to the equation generating the sine wave. If H is defined as 1, the sine wave generated will be the same as the expected VCO output. If H is chosen as some value greater than 1, the frequency of the output will be reduced accordingly. This is useful when running simulations designed to show reference spur levels.

In cases where it is desirable to view reference spur levels, simulation can become difficult or impossible. For example, consider the circuit that is being discussed. This circuit represents the evaluation kit (MC145230EVK) using a VCO tunable between 733 MHz to 742 MHz, with a step frequency of 25 kHz.

### NOTE

This example is for reference only. The maximum operating frequency of the MC145181 is 550 MHz. Operation of the VCO at frequencies greater than 550 MHz requires the inclusion of additional external division such as a prescaler.

To obtain useful information from the simulation, a sampling rate greater than the Nyquist limit must be used (three to five samples per cycle). This dictates a step size less than 1/2 nanosecond. Additionally, the reference frequency is only 25 kHz. To accurately represent the conditions for spur generation, the simulation time must be long enough to include a sufficient number of  $f_r$  periods. Otherwise, no spurs are generated. In addition, the data file system is limited to 2 Gbyte, either in the NT 4.0 operating system or in PSpice itself. If the file exceeds 2 Gbyte, the data is discarded. To simulate reference spur generation at 730 MHz, a 1 ms simulation time was chosen. The simulation ran for several hours and generated a data file just under 2 Gbyte. The result is shown in Figure 48. The plot obtained from the EVK is shown in Figure 49 for comparison.

# MC145181

Figure 46. CPL and CPH Charge Pumps

# MC145181

Figure 47. VCO Model

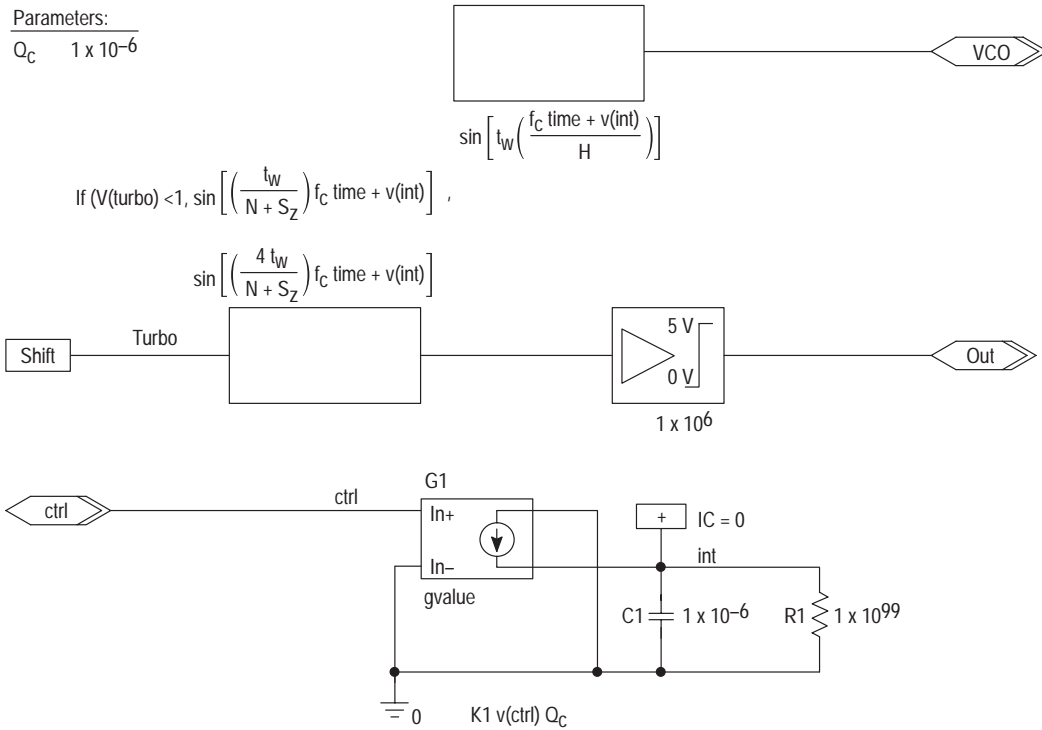

Figure 48. Reference Spur Simulation at 730 MHz

Figure 49. Sybil EVK Reference Spur Measurements

It should be noted that the reference spur values obtained from the simulation are lower than the values obtained from the actual EVK. This is because the simulation model is an “ideal” modeling of the PLL. To obtain results closer to the actual implementation, the models should be “massaged” to be more representative of the actual circuit. For example, spur levels more consistent with actual circuitry can be obtained by adding a resistance to ground at the input of the VCO to represent leakage. The value chosen should be consistent with VCO and circuit component performance.

To reduce simulation time, the H value may be used. By reducing the frequency of the VCO output, the number of samples required for simulation can also be reduced. The output shown in Figure 50 shows the result of dividing the VCO output of 730 MHz by 7.3 to produce a 100 MHz output. The reference spurs are better represented since adequate simulation time is possible.

To generate these outputs, the parameter values used were those shown on the top level schematic. The simulator was set to run a transient sweep, with  $t_d$  set for a delay that would prevent the 4X frequency from being started. The initial conditions were set to 1 V and the simulation run for 1 ms. VCO was monitored and the probe display button FFT was initiated. The X and Y axis were adjusted to those shown.

Note: These simulations are presented as the result of “ideal” models and may not accurately display real hardware. It would be best to load the VCO input with additional leakage devices such as a large resistance, to accurately display real

conditions. These models are starting points for more accurate implementations.

Loop filter analysis is more accurate, since the predominate factors are in the loop filter itself. To simulate the performance of the loop filter,  $t_d$  is set for 0, N is set to the desired divider value, and  $S_z$  is set to the desired step. For this example, 733 MHz was chosen.

#### NOTE

These values are for reference only. The maximum operating frequency of the MC145181 is 550 MHz. For VCO frequencies greater than 550 MHz, an added external divider such as a prescaler is necessary.

With the VCO model shown,  $V(\text{ctrl}) = 0$  produces an output of 727.6 MHz and at  $V(\text{ctrl}) = 1.35$  V, the VCO frequency would be 733 MHz; the minimum MC145230EVK default operating frequency. To show the response of the loop filter to a 10 MHz step at this operating frequency,  $S_z = 10$  MHz/25 kHz = 400. The simulation is run for 1 ms with a step ceiling of 100 ns. The result is shown in Figure 51.

If the simulation is examined over a longer period of time, the long term settling can be compared to the performance of the actual circuitry. The plot shown in Figure 52 shows the VCO control voltage with the display resolution set to 1 mV. This compares to the plot of frequency variation measurements made on the actual EVK. This plot is shown in Figure 53.

# MC145181

Figure 50. H Set to Generate a 100 MHz Output

Figure 51. 10 MHz Step for an Operating Frequency of 729 MHz

Figure 52. VCO Settling

Figure 53. Frequency Settling of the EVK

## MC145181

It is noted that the results obtained from the simulation compare favorably to those obtained from the measurements of the EVK. The simulation display resolution is adjusted to represent the same  $\pm 4$  kHz deviation as shown in Figure 53. Since variation in VCO control voltage is equal to the VCO frequency divided by the VCO gain, this axis may be redefined to show change in frequency rather than change in control voltage.

The models shown represent a "skeleton" that may be used to develop extensive and reliable simulations that can greatly reduce actual breadboarding and testing. In addition to the basic simulations shown, PSpice provides a method by which worst case and Monte Carlo evaluation can be

performed on all, or selected components. By limiting the circuit to minimum necessary components, simulation can be performed using only the PSpice evaluation copy. In addition, the optional PSpice program Optimizer should allow refining the loop filter more easily.

While PSpice is a powerful tool, it is not without limits. Since it was designed to run on large mainframe computers, the PC is just now becoming powerful enough to make use of the capability of the simulator. A fast Pentium class processor with a large RAM and a hard drive of the Gbyte size is a necessity. Even with the most judicious planning, some simulations will "bump" the limits of the system.

7D. SECONDARY LOOP FILTER DESIGN

Low Pass Filter Design for PD<sub>out</sub>'

The design of low pass filtering for PD<sub>out</sub>' for the device can be accomplished using the following design information. In addition to the example included here, Motorola Application Note AN1207, also includes examples of active filtering which may be used to supplement this information.

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC(R_1 + R_2)}}$$

$$\zeta = 0.5 \omega_n \left( R_2 C + \frac{N}{K_\phi K_{VCO}} \right)$$

$$F(s) = \frac{R_2 s C + 1}{(R_1 + R_2) s C + 1}$$

Definitions:

N = Total Division Ratio in Feedback Loop

K<sub>φ</sub> (Phase Detector Gain) = V<sub>DD</sub> / 4π V/radian for PD<sub>out</sub>'

K<sub>φ</sub> (Phase Detector Gain) = V<sub>DD</sub> / 2π V/radian for φ<sub>φ</sub> and φ<sub>R</sub>

$$K_{VCO} \text{ (VCO Gain)} = \frac{2\pi \Delta f_{VCO}}{\Delta V_{VCO}}$$

For a nominal design starting point, the user might consider a damping factor ζ ≈ 0.7 and a natural loop frequency ω<sub>n</sub> ≈ (2πf<sub>R</sub>/50), where f<sub>R</sub> is the frequency at the phase detector input. Larger ω<sub>n</sub> values result in faster loop lock times and, for similar sideband filtering, higher f<sub>R</sub>-related VCO sidebands.

Example:

Given the following information:

VCO frequency = 45.555 MHz,

Frequency step size = 5 kHz,

VCO gain = 3.4 MHz/V.

Design a loop filter with a damping factor of 0.707.

The VCO is assumed to have a linear response throughout the range used in this example. The gain for the VCO has been given as 3.4 MHz/V and is multiplied by 2π rad/s/Hz for calculating loop filter values.

$$K_{VCO} = 2\pi \text{ rad/s/Hz} \times 3.4 \text{ MHz/V} = 2.136 \times 10^7 \text{ rad/s/V}$$

The gain for the phase detector is defined as

$$K_\phi = \frac{V_{DD}}{4\pi} \text{ V/rad for PD}_{out}'$$

Using a value for V<sub>DD</sub> (phase detector supply voltage) of 3.6 V with the output voltage multiplier turned off, the value is

$$K_\phi = \frac{3.6}{4\pi} = 0.2865 \text{ V/rad}$$

Let

$$\omega_n = \frac{2\pi f_R}{50} = 628.3 \text{ rad/s}$$

and

$$N = \frac{F_{VCO}}{F_{\text{step size}}} = \frac{45.555 \text{ MHz}}{5 \text{ kHz}} = 9111$$

Choosing C = 0.05 μF and calculating R<sub>1</sub> + R<sub>2</sub>,

$$R_1 + R_2 = \frac{K_\phi K_{VCO}}{N C \omega_n^2} = 34 \text{ k}\Omega$$

With a damping factor of 0.707,

$$R_2 = \frac{\frac{0.707}{0.5 \omega_n} - \frac{N}{K_\phi K_{VCO}}}{C} = 15 \text{ k}\Omega$$

$$R_1 = (R_2 + R_1) - R_2 = 34 \text{ k} - 15 \text{ k} = 19 \text{ k}\Omega \sim 20 \text{ k}\Omega$$

The choice for C is somewhat arbitrary, however, its value does impact the performance of the loop filter. If possible, a range of choices for C should be used to calculate potential loop filters and the resultant filters simulated, as will be shown below, to determine the best balance.

If additional filtering is desired, R1 may be split into two equal resistors and a capacitor to ground inserted. Since the closest resistance to one-half of 9 k is 4.7 kΩ, this value is chosen for R1<sub>a</sub> and R1<sub>b</sub>. The maximum value for the added capacitance is based on the bandwidth of the original loop filter.

The general form for the transfer function for the passive filter shown in Figure 54, can be shown to have the form:

$$F(s) = K_h \left[ \frac{s + \omega_2}{(s + \omega_1)(s + \omega_3)} \right]$$

where

$$\omega_1 = \frac{1}{(R1_a + R1_b + R2) C}$$

$$\omega_2 = \frac{1}{R2C}$$

$$\omega_3 = \frac{1}{\left[ \frac{R1_a R1_b + R1_a R2}{(R1 + R2)} \right] C_c}$$

where

$$R1 = R1_a + R1_b$$

and

$$\omega_3 > \omega_2$$

Since splitting R1 into two equal values, R1<sub>a</sub> and R1<sub>b</sub>, and inserting the capacitance between the junction of R1<sub>a</sub> and R1<sub>b</sub> does not change the position of the pole located at ω<sub>1</sub>, the value of ω<sub>1</sub> remains

$$\omega_1 = \frac{1}{(R1_a + R1_b + R2) C} = \frac{1}{(R1 + R2) C}$$

The 0 identified at ω<sub>2</sub> = 1/R2 C is also unaffected by the addition of C<sub>c</sub> if ω<sub>3</sub> > ω<sub>2</sub>.

Since

$$R1_a = R1_b = \frac{R1}{2}$$

the value of C<sub>c</sub> can be determined by specifying the value for ω<sub>3</sub> and using the values already determined for R1 and R2. The rule of thumb is to choose ω<sub>3</sub> to be 10 x ω<sub>B</sub> so as not to impact the original filter. ω<sub>B</sub> can be found as

$$\omega_B = \omega_n \sqrt{[1 + 2\zeta^2 + \sqrt{(2 + 4\zeta^2 + 4\zeta^4)}]}$$

$$\omega_B = 628.3 \text{ rad/s} \sqrt{[1 + 2(0.707)^2]}$$

$$+ \sqrt{(2 + 4(0.707)^2 + 4(0.707)^4)}$$

$$= 1.293 \times 10^3 \text{ rad/s}$$

$$10 \omega_B = 12.93 \times 10^3 \text{ rad/s}$$

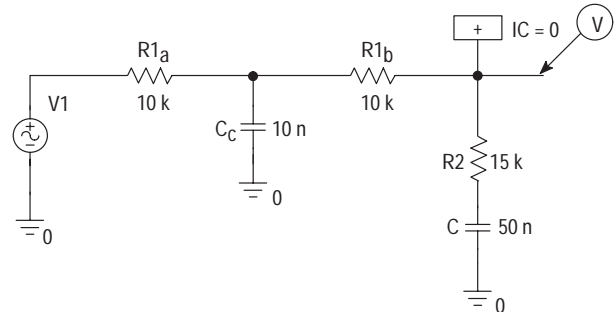

The circuit for the passive loop filter is shown in Figure 54. R1 is split into two equal values and C<sub>c</sub> inserted at the

junction of R1<sub>a</sub> and R1<sub>b</sub>. Using the values defined above, C<sub>c</sub> is determined to be

$$C_c = \frac{1}{\left[ \frac{R1_a R1_b + R1_a R2}{(R1 + R2)} \right] \omega_3}$$

$$= \frac{1}{\left[ \frac{R1_a R1_b + R1_a R2}{(R1 + R2)} \right] 10} = 10.83 \text{ nfd} \sim 10 \text{ nfd}$$

Figure 54. Passive Loop Filter for PD<sub>Out</sub>'

### Open Loop AC Analysis of the Loop Filter

AC analysis is chosen for the mode of simulation for PSpice and VSIN is chosen for V1 and is set to produce a 1 V peak output signal. The simulation is then run and the result shown in Figure 55.

A Bode plot of the loop filter is obtained which describes the open loop characteristics of the loop filter. The corner frequencies of the filter can be modified and the simulation rerun until the desired wave shape is obtained. Since AC analysis runs much faster than transient analysis, the AC open loop analysis of the loop filter is much quicker and requires less resources than the closed loop transient analysis.

### Closed Loop Filter Simulations Using PSpice

The top level schematic for simulating a simple loop filter for PD<sub>Out</sub>' operating closed loop, is shown in Figure 56. This filter uses the values calculated above.

The schematic represents the PLL function using the internal phase detector, PD<sub>Out</sub>', the loop filter calculated above, and a VCO. The parameter table allows altering the divider value of N, the maximum current obtained from PD<sub>Out</sub>', and PD<sub>Out</sub> charge pump voltage from the top level schematic.

The schematic for the VCO is shown in Figure 57. Analog behavioral modeling is used rather than discrete transistor modeling to reduce component count and improve simulation efficiency.

The behavioral VCO is composed of an integrator that transforms the input ctrl into the voltage control V(int) and a sine wave generator function whose frequency is controlled by V(int). EVALUE and GVALUE functions are used to perform the transforms. The analog behavioral models, ABM and ABMI, can also be used.

# MC145181

Figure 55. Bode Plot of the Passive Loop Filter

Figure 56. Passive Loop Filter

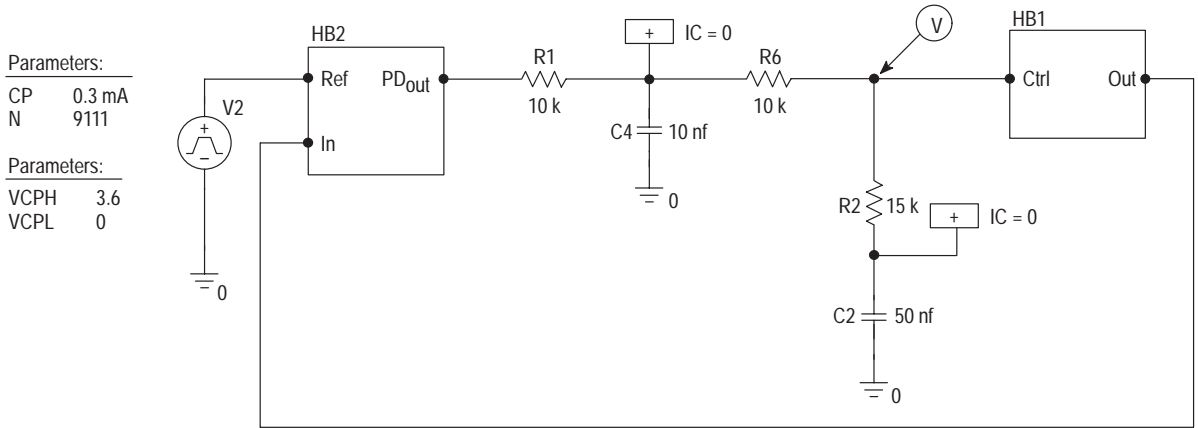

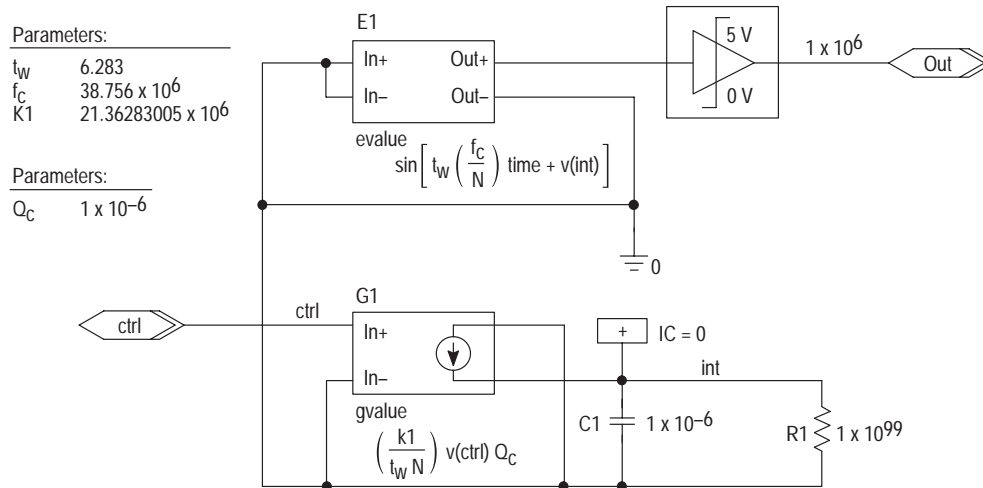

Figure 57. VCO Behavioral Model

G1 performs the operation  $[k1/(t_w N)] v(ctrl) Q_C$ . This integrates the input ctrl to produce a voltage ramp used by E1 to produce the desired output. This input is integrated by C1 whose value should equal  $Q_C$  for most applications. R1 is required by SPICE to prevent a floating node error.

E1 performs the calculations necessary to generate a sine wave of the desired frequency based on the values listed in the parameter tables and the value of ctrl. The output of E1 is multiplied by  $1 \times 10^6$  and limited to 0 and 5 to obtain a square wave with a fast rise/fall time. Since I/O\_STM is a standard model whose values are 0 and 5, these are used here and in the phase detector rather than modifying the component libraries.

The parameter tables provide a convenient method for setting VCO parameters.  $t_w$  is  $2\pi$ ,  $f_c$  is the zero control voltage VCO frequency, and K1 is the VCO gain in rad/s/V.

The sub-schematic for the phase/frequency detector section of the drawing is shown in Figure 58. This is composed of two blocks, HB3 and HB4. HB3 performs the PD<sub>Out'</sub> function with HB4 performing the actual phase detector operation.

The circuit for the phase/frequency detector is shown in Figure 59. The model is made up of two pulse generators, two RS flip-flops, and appropriate behavioral gates.

HB1 and HB2 are RS flip-flops. These are constructed from behavioral blocks as shown in Figure 60. A behavioral AND gate with a 5 ns delay completes the three state ( $\pm 2\pi$ ) phase/frequency detector. The STP function ensures the RS flip-flops are reset at initiation.

To perform the phase detector function, the Ref and  $f_{in}$  inputs of the behavioral RS flip-flops are configured to simulate edge triggered operation. This is achieved by placing a 1 ns delay in the Ref and  $f_{in}$  signal paths. The input and output of the delay are compared by the input behavioral block and interpreted as a 1 ns pulse. These pulses are used to set HB1 and HB2. If  $f_{in}$  leads Ref, the In flip-flop, HB2, will be set first. When Ref leads  $f_{in}$ , the Ref flip-flop, HB1, will be set first. The lagging edge drives the second flip-flop output high and the behavioral AND gate then resets both flip-flops. The delay line at the output of the behavioral AND gate prevents PSpice from being confused and also completes the simulation of the phase detector. The outputs of the two RS flip-flops are labeled  $R_\phi$  and  $V_\phi$ . The time between the

leading and lagging edges is reflected in the pulse width of the leading edge flip-flop. The lagging edge flip-flop will display a narrow pulse equal in width to the value chosen for the delay at the output of the behavioral AND gate. This should be programmed to the minimum value as specified by the data sheet and is usually 5 ns or less.

Since the outputs  $R_\phi$  and  $V_\phi$  are pure logic signals, additional circuitry is necessary to produce the output PD<sub>Out'</sub>. This output should be high impedance when not driving, and pull either high or low depending on which function ( $R_\phi$  or  $V_\phi$ ) is active. The circuitry shown in Figure 61 performs this function.

To eliminate the need for discrete modeling of PD<sub>Out'</sub>, analog behavioral modeling is used. Analog behavioral blocks ABMI/2, generate a current source/sink output whenever the appropriate input is high.

A second set of behavioral blocks monitor the output drive, and switch on the appropriate voltage controlled switch whenever the output rises to the value of  $V_{DD}$  (phase detector supply voltage) or drops to 0.

To model PD<sub>Out'</sub>, either a model of the transistors used for PD<sub>Out'</sub> must be used or this behavioral arrangement can be used. Since the output is specified by a specific output level and current capability, this arrangement suffices. The output swing becomes VCPH in the schematic and the current capability is CP. If a non-zero value is desired for  $V_{IO}$ , the value VCPL is adjusted from the parameter table on the top level schematic.

This arrangement allows setting the output voltage swing of PD<sub>Out'</sub> by specifying VCPH, the current drive of PD<sub>Out'</sub> by specifying the desired value for CP, and leakage values can be simulated by setting the appropriate attributes for S1 and S4 or by adding additional resistance.

### Simulation

Figures 62 and 63 are the simulation results of running a transient analysis on the example shown above. The time to lock from power on is simulated by setting the initial condition (IC1) to 0 and running the simulation. Figure 62 is the time versus value of the VCO control voltage. Figure 63 shows the output at the input of the loop filter and can be used to determine lock time.

### Summary

PSpice provides a method by which the performance of PLL circuitry can be simulated prior to, or in addition to, laboratory testing. The use of behavioral modeling allows the creation of simulation circuits that can provide valuable information for loop filter design and adjustment. By judicious

attention to VCO modeling, expected output characteristics can be verified prior to laboratory testing. While simulation does not replace laboratory testing, it can be used to find solutions to “what if” questions without the need for extensive empirical data gathering.

## 7E. VOLTAGE MULTIPLIER STALL AVOIDANCE

There are three important criteria to note, highlighted in the following sections: **Allowing for Voltage Build**, **Ensuring Valid Counter Programming**, and **Allowing for Overshoot**. Violation of any of these may cause the voltage multiplier to collapse. Once the voltage collapses, the loop goes out of lock and can not recover until the voltage is allowed to build up again. For an active loop, the voltage multiplier is designed to *maintain* the multiplied voltage on the phase/frequency detector supply pin ( $C_{mult}$ ). If the main loop is active, the multiplier cannot build the voltage.

### Allowing for Voltage Build

After power up, a sufficient time interval must be provided for the on-chip voltage multiplier to build up the voltage on the  $C_{mult}$  pin. During this interval, the phase/frequency detector outputs for the main loop ( $PD_{out-Hi}$  and  $PD_{out-Lo}$ ) must be inactive (floating outputs). The POR (power-on reset) circuit forces this “float” condition, thus allowing the voltage to build on the  $C_{mult}$  pin.

The duration of the interval to build the voltage is determined by the external capacitor size tied to the  $C_{mult}$  pin and the charging current which is 100  $\mu$ A minimum. The following formula may be used:

$$T = CV/I$$

where

- T is the interval in seconds,
- C is the  $C_{mult}$  capacitor size in farads,
- V is the desired voltage on  $C_{mult}$  in volts, and
- I is the charging current,  $1 \times 10^{-4}$  amps.

The desired voltage on  $C_{mult}$  is 4 V for a nominal 2 V supply and 5 V for any supply above 2.6 V.

After this interval, the chip can maintain the voltage on the  $C_{mult}$  pin and the phase detectors may be safely placed in the active state.

The interval above also applies when the voltage multiplier is turned off (with power applied) via bits R'19 R'18 R'17 being 000. After the multiplier is turned back on, sufficient time must be allowed for the voltage to build on  $C_{mult}$ . In this case, typically an external resistor does not allow the  $C_{mult}$  voltage to discharge below approximately  $V_{pos}$  (see Section 5E, under  **$C_{mult}$** ). Note that if the voltage multiplier is NOT turned off (that is, the above bits are unequal to 000), the keep-alive circuit maintains the multiplied voltage on  $C_{mult}$ .

### Ensuring Valid Counter Programming

Before the PLLs and/or phase detectors are taken out of standby, legitimate divide ratios (pertinent to the application) must be loaded in the registers. For example, proper divide ratios must be loaded for the R, N, R', and N' counters. Also, proper values for all other bits must be loaded. For example: selection of crystal or external reference mode must be made prior to activation of the loops.

After the IC is initialized with the proper bits loaded, the main loop may then be safely activated via the phase detector float bit and/or the PLL standby bit being programmed to 0.

### Allowing for Overshoot

The VCO control voltage overshoot for the main loop must not be allowed to exceed the capability of the phase/frequency detectors' maximum output voltage. The

detectors' maximum output voltage is determined by the minimum voltage at  $C_{mult}$  and the headroom required for the current source. See the following figure.

For example, if the main supply voltage ( $V_{pos}$ ) is 3 V and the voltage multiplier is utilized, the minimum voltage at  $C_{mult}$  is 4.75 V. Then, to allow for current source headroom, the maximum output voltage from the parameter table in Section 3C is approximately  $C_{mult} - 0.6$  V or 4.2 V approximately. Thus, the maximum output overshoot voltage at the phase/frequency detector outputs should be no more than 4.2 V.

Continuing the above example, if the loop is designed with 20% overshoot in the VCO control voltage, then the overshoot must be subtracted off of the 4.2 V shown above. Therefore, the upper end of the control voltage to the VCO must be no more than approximately 3.64 V.

The equations below can be used to determine constraints:

$$\Delta V \leq \frac{V_{\phi} - 1.2}{2\alpha + 1}$$

$$SSV_{max} = V_{\phi} - \alpha (\Delta V) - 0.6$$

where

$\Delta V$  is the VCO control voltage range, the maximum minus the minimum voltage,

$V_{\phi}$  is the minimum phase detector supply voltage (at the  $C_{mult}$  pin) per the following table,

$\alpha$  is the control voltage overshoot in decimal; for example, 20% overshoot is 0.2, and

$SSV_{max}$  is the maximum allowed steady-state VCO control voltage.

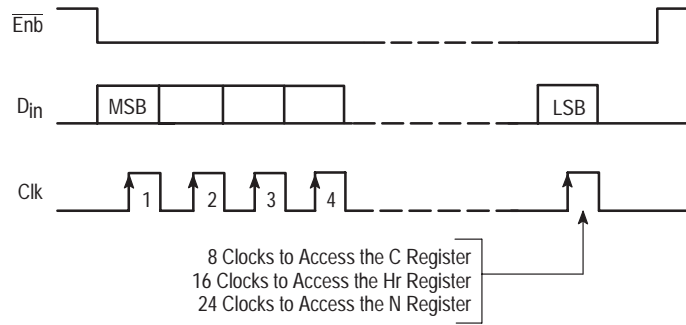

### MINIMUM PHASE DETECTOR VOLTAGE FROM VOLTAGE MULTIPLIER

Supply Voltage, $V_{pos}$	Minimum Phase Detector Voltage, $V_{\phi}$
1.8 V	3.32 V
2.0 V	3.72 V
2.5 V	4.75 V
3.6 V	4.75 V

## 8B. INITIALIZING THE DEVICE

### Introduction

The registers retain data as long as power is applied to the device. The R and N registers contain counter divide ratios for the main loop, PLL. The R' and N' registers contain counter divide ratios for the secondary loop, PLL'. Additional control bits are located in the R', N, and C registers. The D register controls the DACs. Section 8A is a handy reference for register access and bit definitions.

The C, D, R', and N registers can be directly written, and have an immediate impact on chip operation. The Hr and Hn' registers can be directly written, but have no immediate impact on chip operation. This is because the Hr and Hn' registers are the front-ends of double buffers. The Hr register feeds the R register. The Hn' register feeds the N' register. Changing data in the R and/or N' registers is done with a write to the Hr and/or Hn' register, respectively, followed by a write to the N register. The transfer of data from the Hr to R and Hn' to N' registers is triggered with a write to the N register.

Typically, the Hr and Hn' registers are written once, during initialization after power up. The Hr and Hn' registers only need to be accessed if their data is changing.

### An Example

Following is an initialization example for a system with a main loop that covers 450 to 500 MHz in 5 kHz steps. An external reference of 19.44 MHz is utilized. The secondary loop is selected to run at 50 MHz. Both VCOs are positive polarity meaning that when the input control voltage increases, the output frequency increases. A divided-down reference is not needed ( $f_{out}$  and  $\overline{f_{out}}$ ). Therefore, the Mode pin is tied to  $V_{POS}$  and the Pol and Pol' pins are tied to ground.

The following initialization gives serial data examples for BitGrabber access of the C, Hr, and N registers.

### Initialization

Below is the six-step initialization sequence used after power up for the example given above.

Programming the C register first is recommended if the voltage multiplier is utilized. There are three important criteria to note. Violation of any criterion may cause the voltage multiplier to collapse. The first criterion is that after power up, a sufficient time interval must be provided (after the C and R' registers are initialized) for the on-chip voltage multiplier to build up the voltage on the  $C_{MULT}$  pin. This interval is determined by the external capacitor size tied to the  $C_{MULT}$  pin and the charging current which is about 100  $\mu$ A. After this interval, the chip can maintain the voltage on the  $C_{MULT}$  pin and the phase/frequency detectors for the main loop may be safely activated. The second criterion is that before the phase/frequency detectors are activated, legitimate divide ratios (pertinent to the application) must be loaded in the registers. The third criterion is a hardware issue. The three criteria are discussed with more detail in Section 7E.

If the voltage multiplier is not used, Step 1 is eliminated and the initialization sequence starts with Step 2.

#### Step 1: Load the C Register

The C register is programmed such that the main loop's phase/frequency detector outputs are floating (PD Float bit  $C4 = 1$ ), the reference circuit is active (Osc Stby bit  $C2 = 0$ ),

and an external reference is accommodated (Out B/Xref bit  $C6 = 1$ , with the Mode pin high). When the voltage multiplier is enabled by programming the R' register, the voltage is allowed to build on the  $C_{MULT}$  pin such that a voltage higher than the main supply voltage is providing power to the phase/frequency detectors. Both loops are active (PLL Stby bits  $C1 = C0 = 0$ ). Also, for this example, Output A and Output C are programmed low (Out bits  $C7 = C5 = 0$ ).

In summary, hexadecimal 58 or \$58 is serially transferred (BitGrabber access with no address bits).

#### Step 2: Load the R' Register

For the secondary loop, the 19.44 MHz reference must be divided down to 80 kHz by the R' counter; the divide ratio is 243. Per Section 8A, the value is doubled to 486. The 16 LSBs of the R' register determine the R' counter divide ratio. Therefore, 486 is converted to \$01E6 and becomes the 16 LSBs (R'15 to R'0) in the R' register. Test/Rst bit R'16 must be a 0. Bits R'19 to R'17 determine the refresh rate of the voltage multiplier. The frequency at  $Osc_e$  is <20 MHz. Therefore, per Section 8A, bits R'19 to R'17 must be 001. If Output A is needed as a MCU port expander, bits R'21 = R'20 = 0. Per Section 8A, Y Coefficient bits R'23 = R'22 = 0.

In summary, \$050201E6 is serially transferred (conventional access with an address of 0101).

#### Step 3: Load the Hr Register

For the main loop, the 19.44 MHz reference must be divided down to 5 kHz by the R counter; the divide ratio is 3888. Per Section 8A, the ratio 3888 is doubled to 7776 and then converted to \$1E60. The Hr register value is programmed as \$1E60. When the Hr register contents are transferred to the R register, the R counter divide ratio is determined.

In summary, \$1E60 is serially transferred (BitGrabber access). This value is transferred from the Hr to the R register when the N register is accessed in Step 5.

#### Step 4: Load the Hn' Register

For the secondary loop, the phase detector is chosen to run at 80 kHz. Therefore, 80 kHz must be multiplied up to 50 MHz which is a factor of 625. Per Section 8A, the factor is first multiplied by 8 which equals 5000 and then converted to \$1388. The Hn' register is programmed as \$1388. When the Hn' register contents are transferred to the N' register, the N' counter divide ratio is determined.

In summary, \$04001388 is serially transferred (conventional access with an address of 0100). The value \$1388 is transferred to the N' register when the N register is accessed in Step 5.

#### Step 5: Load the N Register

For this example, the IC is initialized to tune the lowest end of the main loop. The lowest end of the main loop's frequency range is 450 MHz. Therefore, the 5 kHz must be multiplied up to 450 MHz which is a factor of 90,000 or \$15F90 to be loaded into bits N17 to N0 of the N register. Bit N18 is programmed to 0 for a PD<sub>OUT</sub>-Hi to PD<sub>OUT</sub>-Lo current ratio of 4:1. If PD<sub>OUT</sub>-Lo is used for the main loop, bits N21 to N19 must be 001. (PD<sub>OUT</sub>-Lo must be used to initialize the device when *adapt* is used, see Section 8D.) Bit N22 = 0 to select a lock detect window of approximately  $32 / Osc_e = 32 / 19.44 \text{ MHz}$  or 1.6  $\mu$ s. Bit N23 must be programmed to 1

by the user. (When the Mode pin is high, programming N23 to a 0 is for Motorola use only.)

In summary, \$895F90 is serially transferred (BitGrabber access). The N register access also causes double-buffer transfers of Hr to R and Hn' to N'.

### Step 6: Load the C Register

Now that legitimate divide ratios are programmed for the counters, the main loop may be activated. Thus, the PD float bit C4 is now programmed to 0. The standby bits are unchanged: C2 = C1 = C0 = 0. Bit C5 could be used to control Output C to either a low level or high impedance; for a low level, C5 = 0. Whenever an external reference is utilized, bit C6 must be 1. Bit C7 may be used to control Output A to a low or high level because it is selected as "port expander" by bit R'21 and R'20; for a low level, C7 = 0.

In summary, \$40 is serially transferred (BitGrabber access). This causes the main loop to tune to 450 MHz, the secondary loop to tune to 50 MHz, and both the Output A and Output C pins to be forced low.

The device is now initialized.

## 8C. PROGRAMMING WITHOUT ADAPT

### Tuning the Top of the Band

After initializing the device via steps 1 through 6 in Section 8B, the only register that needs to be loaded to tune the main loop is the N register.

For this example, tuning the upper end of the band (500 MHz) requires that the 5 kHz at the phase/frequency detector be multiplied up to 500 MHz. This is a loop multiplying factor of 100,000. This value is converted to \$186A0 and is loaded for bits N17 to N0. Bits N23 to N18 are not changed and are programmed as indicated in Section 8B, step 5.

In summary, \$8986A0 is transferred to tune the main loop. No other registers are loaded.

### Tuning Other Channels

Tuning other channels for the main loop, while keeping the secondary loop at a constant frequency, only requires programming the N register. See Table 22 for example frequencies.

Table 22. Main Loop Tuning Examples

Frequency Desired (MHz)	Multiplying Factor (Decimal)	Multiplying Factor (Hexadecimal)	N Register Data (Hexadecimal)
450.000	90,000	\$15F90	\$895F90
450.005	90,001	\$15F91	\$895F91
450.010	90,002	\$15F92	\$895F92
450.015	90,003	\$15F93	\$895F93
455.000	91,000	\$16378	\$896378
458.015	91,603	\$165D3	\$8965D3
471.040	94,208	\$17000	\$897000
500.000	100,000	\$186A0	\$8986A0

## 8D. PROGRAMMING UTILIZING HORSESHOE WITH ADAPT

### Introduction

A unique adapt feature can be used with the MC145181 when conventional tuning can not meet the lock-time requirements of a system and the annoying spurs or noise can not be tolerated from a fractional-N scheme. The adapt feature is available on the main loop only.

For adapt, a timer is engaged which causes an internal data update of the R and N registers to be delayed. The IC supports the *Horseshoe* scheme for adapt by allowing a fairly-close quickly-tuned *approximate* frequency to be tuned, followed by the tuning of the *exact* frequency. Two sets of R and N data are sent to the device. The first set {R1, N1} is for tuning the approximate frequency. The second set {R2, N2} is for tuning the exact frequency. Use of the timer delays the transfer of {R2, N2} until a programmed interval has elapsed. In addition, after the interval has elapsed, the main loop control switches from PD<sub>Out-Hi</sub> to PD<sub>Out-Lo</sub>.

### Tuning Near the Top of the Band

Continuing the example, after initializing the device via steps 1 through 6 in Section 8B, Horseshoe with adapt can be used to tune the main loop to obtain fast frequency jumps. Use of the BitGrabber access is recommended to minimize the number of serial data clocks required for sending the four "words".

In this example, the first phase of adapt utilizes approximate tuning with the phase/frequency detector running at 4x the step size. Therefore, the approximate tuning runs the detector at about 20 kHz. The second phase, with exact tuning, runs the detector at 5 kHz. Horseshoe with adapt requires that two data sets be serially sent to the device for every frequency tuned. The first set is for approximate tuning {R1, N1}; the second set is for exact tuning {R2, N2}.

Approximate tuning with Horseshoe is unique. This method involves two key elements: (1) increasing the phase detector frequency and (2) varying *both* the R and N divide values such that the approximate frequency is within a certain predetermined range. The Horseshoe algorithm contained in the development system software also allows placing a constraint on the loop-gain variation that the user can tolerate.

For example, to tune 459.97 MHz, the first {R1, N1} data set could contain divide ratios for the R and N counters of 973.5 and 23,034, respectively. With this data set, the phase detector is running at about 19.97 kHz and the approximate frequency is about 170 Hz from the exact frequency. The second data set contains R and N divide values of 3,888 and 91,994, respectively. This achieves the exact (target) frequency of 459.97 MHz.

The timer must be programmed to determine the interval that the device is in the approximate-tune mode. For this example, assume this is 32 f<sub>R</sub> cycles; thus, bits N21 N20 N19 = 1 0 1 in the first data set. Note that this time interval is 32 cycles of f<sub>R</sub>, with the phase detector running at about 20 kHz (approximate tune) or about 1.6 ms plus the MCU shift time shown in Figure 64. Included in the first data set are N23 = 1 which is required when the Mode pin is high, N22 = 0

for the lock detect window of 1.6  $\mu$ s, and N18 = 0 for a current ratio of 4:1 (because the phase detector is running at approximately 4x the step size). Note that bits N23, N22, and N18 are unchanged from the initialization values.

For the second data set, bits N23, N22, and N18 are unchanged. Bits N21, N20, and N19 must be programmed as 001. This enables PD<sub>Out-Lo</sub> for the exact tune after time out.

In summary, two data sets need to be sent to the device: {R1, N1} and {R2, N2}. They are sent in succession as R1, N1, R2, N2; where R1 is the R register value for the first data set, N1 is the N register value for the first set, etc. For the example, these values are {R1, N1} = {\$079B, \$A859FA} and {R2, N2} = {\$1E60, \$89675A}. See Figure 64.

### Tuning Other Channels

Tuning other channels for the main loop, while keeping the secondary loop at a constant frequency, requires sending two data sets to the part {R1, N1} and {R2, N2}. See Table 23.

## 8E. CONTROLLING THE DACs

### Introduction

The two 8-bit DACs are independent circuit blocks on the chip. They have no interaction with other circuits on the chip. A single 16-bit register, called the D register, holds the binary value which controls both DACs.

### Programming the DACs

A DAC programmed for 0 scale is in the low-power mode. The 0 scale is programmed as \$00 for each 8-bit DAC.

As an example, consider a system that uses just one of the DACs (DAC 1). The other DAC output is unused and is programmed for 0 output. If a condition for a system requires that the DAC have a half-scale output, then DAC 1 is programmed as \$80.

In summary, \$03000080 is serially transferred (conventional access with an address of 0011).

**Table 23. Main Loop Tuning Using Horseshoe With Adapt**

Desired Target Frequency (MHz)	Approximate Tuning			Exact Tuning	
	R1	N1	Frequency Error (Hz)	R2	N2
450.000	\$0798	\$A857E4	0	\$1E60	\$895F90
450.005	\$079B	\$A85807	548	\$1E60	\$895F91
450.020	\$0798	\$A857E5	0	\$1E60	\$895F94
450.255	\$0795	\$A857CE	162	\$1E60	\$895FC3
459.970	\$079B	\$A859FA	170	\$1E60	\$89675A
500.000	\$0798	\$A861A8	0	\$1E60	\$8986A0

Figure 64. Serial Data Format for Horseshoe with Adapt

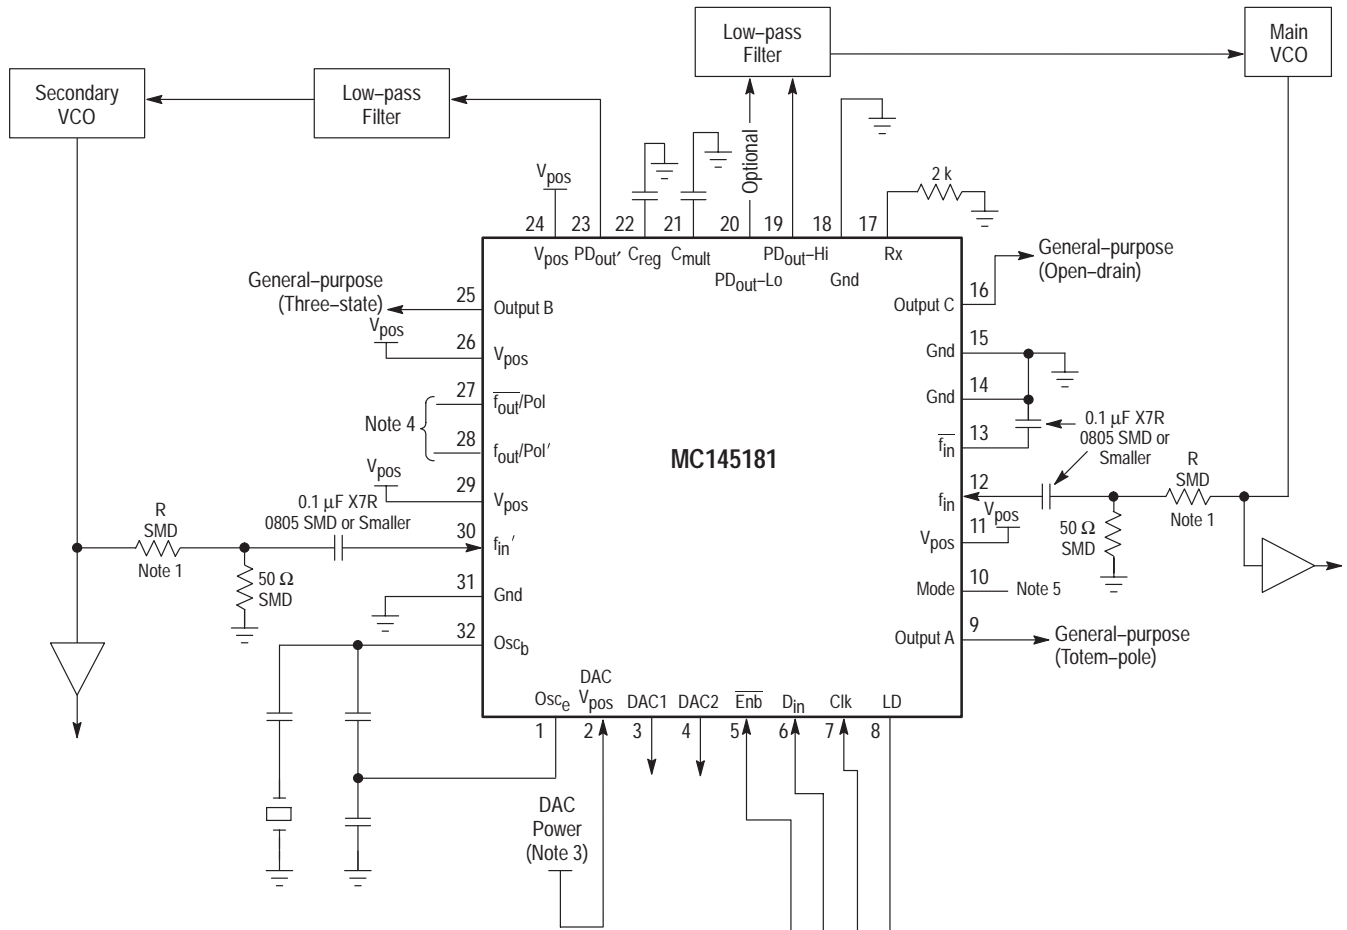

**NOTE:** The interval for shifting in Exact Tune {R2, N2} data adds to the actual Approximate Tuning time. However, this is usually insignificant. For example, at a data rate of 2 Mbps (2 megabits per second), approximately 20  $\mu\text{s}$  is added to the Approximate Tuning time.

# MC145181

## 9. APPLICATION CIRCUIT

Figure 65. Application Circuit

- NOTES:**
1. R should be chosen to achieve the desired isolation. Use of a capacitor in place of R is possible, but there is the possibility of phase locking on VCO harmonics if they fall on the high-sensitivity point of the  $f_{in}$  or  $f_{in}'$  input. This is because use of a capacitor in place of R forms a high-pass filter.
  2.  $V_{pos}$  may range from 1.8 to 3.6 V.
  3. DAC power may be any potential between 1.8 V and 3.6 V.
  4. Configurable pins. See Pin Descriptions.
  5. Tie mode to Gnd or  $V_{pos}$ .

# 1.1 GHz PLL Frequency Synthesizer

## Includes On-Board 64/65 Prescaler

The MC145191 is a single-package synthesizer with serial interface capable of direct usage up to 1.1 GHz. A special architecture makes this PLL very easy to program because a byte-oriented format is utilized. Due to the patented BitGrabber™ registers, no address/steering bits are required for *random access* of the three registers. Thus, tuning can be accomplished via a 3-byte serial transfer to the 24-bit A register. The interface is both SPI and MICROWIRE™ compatible.

The device features a single-ended current source/sink phase detector output and a double-ended phase detector output. Both phase detectors have linear transfer functions (no dead zones). The maximum current of the single-ended phase detector output is determined by an external resistor tied from the Rx pin to ground. This current can be varied via the serial port.

The MC145191 has phase/frequency detectors optimized for single-supply systems of 5 V ±10%.

The part includes a differential RF input which may be operated in a single-ended mode. Also featured are on-board support of an external crystal and a programmable reference output. The R, A, and N counters are fully programmable. The C register (configuration register) allows the part to be configured to meet various applications. A patented feature allows the C register to shut off unused outputs, thereby minimizing system noise and interference.

In order to have consistent lock times and prevent erroneous data from being loaded into the counters, on-board circuitry synchronizes the update of the A register if the A or N counters are loading. Similarly, an update of the R register is synchronized if the R counter is loading.

The double-buffered R register allows new divide ratios to be presented to the three counters (R, A, and N) simultaneously.

- Maximum Operating Frequency: 1100 MHz @  $V_{in} = 200$  mV p-p
- Operating Supply Current: 7 mA Nominal
- Operating Supply Voltage Range ( $V_{DD}$  and  $V_{CC}$  Pins): 4.5 to 5.5 V
- Operating Supply Voltage Range of Phase Detectors ( $V_{PD}$  Pin): 4.5 to 5.5 V
- Current Source/Sink Phase Detector OUTPUT Capability: 2 mA Maximum
- Gain of Current Source/Sink Phase/Frequency Detector Controllable via Serial Port
- Operating Temperature Range: -40 to +85°C
- R Counter Division Range: (1 and) 5 to 8191
- Dual-Modulus Capability Provides Total Division up to 262,143
- High-Speed Serial Interface: 4 Mbps
- OUTPUT A Pin, When Configured as Data Out, Permits Cascading of Devices
- Two General-Purpose Digital Outputs — OUTPUT A: Totem-Pole (Push-Pull)  
OUTPUT B: Open-Drain
- Patented Power-Saving Standby Feature with Orderly Recovery for Minimizing Lock Times, Standby Current: 30  $\mu$ A
- Evaluation Kit Available (Part Number MC145191EVK)
- See Application Note AN1253/D for Low-Pass Filter Design, and AN1277/D for Offset Reference PLLs for Fine Resolution or Fast Hopping

NOT RECOMMENDED FOR NEW DESIGN  
DEVICES TO BE PHASED OUT.  
Consider MC145193 for New Designs.

### PIN ASSIGNMENT

## BLOCK DIAGRAM

### MAXIMUM RATINGS\* (Voltages Referenced to GND, unless otherwise stated)

Symbol	Parameter	Value	Unit
$V_{CC}$ , $V_{DD}$	DC Supply Voltage (Pins 12 and 14)	- 0.5 to + 6.0	V
$V_{PD}$	DC Supply Voltage (Pin 5)	$V_{DD} - 0.5$ to + 6.0	V
$V_{in}$	DC Input Voltage	- 0.5 to $V_{DD} + 0.5$	V
$V_{out}$	DC Output Voltage (except OUTPUT B, $PD_{out}$ , $\phi_R$ , $\phi_V$ )	- 0.5 to $V_{DD} + 0.5$	V
$V_{out}$	DC Output Voltage (OUTPUT B, $PD_{out}$ , $\phi_R$ , $\phi_V$ )	- 0.5 to $V_{PD} + 0.5$	V
$I_{in}$ , $I_{PD}$	DC Input Current, per Pin (Includes $V_{PD}$ )	$\pm 10$	mA
$I_{out}$	DC Output Current, per Pin	$\pm 20$	mA
$I_{DD}$	DC Supply Current, $V_{DD}$ and GND Pins	$\pm 30$	mA
$P_D$	Power Dissipation, per Package	300	mW
$T_{stg}$	Storage Temperature	- 65 to + 150	$^{\circ}C$
$T_L$	Lead Temperature, 1 mm from Case for 10 seconds	260	$^{\circ}C$

\* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit.

## ELECTRICAL CHARACTERISTICS

( $V_{DD} = V_{CC} = 4.5$  to  $5.5$  V, Voltages Referenced to GND,  $T_A = -40$  to  $+85^\circ\text{C}$ , unless otherwise stated;  
 $V_{PD} = 4.5$  to  $5.5$  V with  $V_{DD} \leq V_{PD}$ .)

Symbol	Parameter	Test Condition	Guaranteed Limit	Unit
$V_{IL}$	Maximum Low-Level Input Voltage ( $D_{in}$ , CLK, $\overline{ENB}$ , $REF_{in}$ )	Device in Reference Mode, dc Coupled	$0.3 \times V_{DD}$	V
$V_{IH}$	Minimum High-Level Input Voltage ( $D_{in}$ , CLK, $\overline{ENB}$ , $REF_{in}$ )	Device in Reference Mode, dc Coupled	$0.7 \times V_{DD}$	V
$V_{hys}$	Minimum Hysteresis Voltage (CLK, $\overline{ENB}$ )		300	mV
$V_{OL}$	Maximum Low-Level Output Voltage ( $REF_{out}$ , OUTPUT A)	$I_{out} = 20 \mu\text{A}$ , Device in Reference Mode	0.1	V
$V_{OH}$	Minimum High-Level Output Voltage ( $REF_{out}$ , OUTPUT A)	$I_{out} = -20 \mu\text{A}$ , Device in Reference Mode	$V_{DD} - 0.1$	V
$I_{OL}$	Minimum Low-Level Output Current ( $REF_{out}$ , LD, $\phi_R$ , $\phi_V$ )	$V_{out} = 0.4$ V	0.36	mA
$I_{OH}$	Minimum High-Level Output Current ( $REF_{out}$ , LD, $\phi_R$ , $\phi_V$ )	$V_{out} = V_{DD} - 0.4$ V for $REF_{out}$ , LD $V_{out} = V_{PD} - 0.4$ V for $\phi_R$ , $\phi_V$	-0.36	mA
$I_{OL}$	Minimum Low-Level Output Current (OUTPUT A, OUTPUT B)	$V_{out} = 0.4$ V	1.0	mA
$I_{OH}$	Minimum High-Level Output Current (OUTPUT A, Only)	$V_{out} = V_{DD} - 0.4$ V	-0.6	mA
$I_{in}$	Maximum Input Leakage Current ( $D_{in}$ , CLK, $\overline{ENB}$ , $REF_{in}$ )	$V_{in} = V_{DD}$ or GND, Device in XTAL Mode	$\pm 1.0$	$\mu\text{A}$
$I_{in}$	Maximum Input Current ( $REF_{in}$ )	$V_{in} = V_{DD}$ or GND, Device in Reference Mode	$\pm 150$	$\mu\text{A}$
$I_{OZ}$	Maximum Output Leakage Current ( $PD_{out}$ )	$V_{out} = V_{PD} - 0.5$ V or $0.5$ V, Output in High-Impedance State	$\pm 200$	nA
$I_{OZ}$	Maximum Output Leakage Current (OUTPUT B)	$V_{out} = V_{PD}$ or GND, Output in High-Impedance State	$\pm 10$	$\mu\text{A}$
$I_{STBY}$	Maximum Standby Supply Current ( $V_{DD} + V_{PD}$ Pins)	$V_{in} = V_{DD}$ or GND; Outputs Open; Device in Standby Mode, Shut-Down Crystal Mode or $REF_{out}$ -Static-Low Reference Mode; OUTPUT B Controlling $V_{CC}$ per Figure 22	30	$\mu\text{A}$
$I_{PD}$	Maximum Phase Detector Quiescent Current ( $V_{PD}$ Pin)	Bit C6 = High Which Selects Phase Detector A, $PD_{out}$ = Open, $PD_{out}$ = Static Low or High, Bit C4 = Low Which is <b>not</b> Standby, $I_{RX} = 113 \mu\text{A}$	600	$\mu\text{A}$
		Bit C6 = Low Which Selects Phase Detector B, $\phi_R$ and $\phi_V$ = Open, $\phi_R$ and $\phi_V$ = Static Low or High, Bit C4 = Low Which is <b>not</b> Standby	30	
$I_T$	Total Operating Supply Current ( $V_{DD} + V_{PD} + V_{CC}$ Pins)	$f_{in} = 1.1$ GHz; $REF_{in} = 13$ MHz @ 1 V p-p; OUTPUT A = Inactive and No Connect; $REF_{out} \pm 8$ ; $\phi_V$ , $\phi_R$ , $PD_{out}$ , LD = No Connect; $D_{in}$ , $\overline{ENB}$ , CLK = $V_{DD}$ or GND, Phase Detector B Selected (Bit C6 = Low)	*	mA

\* The nominal value = 7 mA. This is not a guaranteed limit.

### ANALOG CHARACTERISTICS—CURRENT SOURCE/SINK OUTPUT—PD<sub>out</sub>

( $I_{out} \leq 2 \text{ mA}$ ,  $V_{DD} = V_{CC} = 4.5 \text{ to } 5.5 \text{ V}$ ,  $V_{DD} \leq V_{PD}$ . Voltages Referenced to GND)

Parameter	Test Condition	V <sub>PD</sub>	Guaranteed Limit	Unit
Maximum Source Current Variation (Part-to-Part)	$V_{out} = 0.5 \times V_{PD}$	4.5	$\pm 20$	%
		5.5	$\pm 20$	
Maximum Sink-vs-Source Mismatch (Note 3)	$V_{out} = 0.5 \times V_{PD}$	4.5	12	%
		5.5	12	
Output Voltage Range (Note 3)	$I_{out}$ Variation $\leq 20\%$	4.5	0.5 to 4.0	V
		5.5	0.5 to 5.0	

#### NOTES:

1. Percentages calculated using the following formula: (Maximum Value – Minimum Value) / Maximum Value.
2. See Rx Pin Description for external resistor values.
3. This parameter is guaranteed for a given temperature within  $-40^\circ$  to  $+85^\circ\text{C}$ .

### AC INTERFACE CHARACTERISTICS ( $V_{DD} = 4.5 \text{ to } 5.5 \text{ V}$ , $T_A = -40 \text{ to } +85^\circ\text{C}$ , $C_L = 50 \text{ pF}$ , Input $t_r = t_f = 10 \text{ ns}$ ;

$V_{PD} = 4.5 \text{ to } 5.5 \text{ V}$  with  $V_{DD} \leq V_{PD}$ )

## PIN DESCRIPTIONS

### DIGITAL INTERFACE PINS

#### D<sub>in</sub> Serial Data Input (Pin 19)

The bit stream begins with the most significant bit (MSB) and is shifted in on the low-to-high transition of CLK. The bit pattern is 1 byte (8 bits) long to access the C or configuration register, 2 bytes (16 bits) to access the first buffer of the R register, or 3 bytes (24 bits) to access the A register (see Table 1). The values in the C, R, and A registers do not change during shifting because the transfer of data to the registers is controlled by  $\overline{\text{ENB}}$ .

#### CAUTION

The value programmed for the N-counter must be greater than or equal to the value of the A-counter.

The 13 least significant bits (LSBs) of the R register are double-buffered. As indicated above, data is latched into the first buffer on a 16-bit transfer. (The 3 MSBs are not double-buffered and have an immediate effect after a 16-bit transfer.) The second buffer of the R register contains the 13 bits for the R counter. This second buffer is loaded with the contents of the first buffer when the A register is loaded (a 24-bit transfer). This allows presenting new values to the R, A, and N counters simultaneously. If this is not required, then the 16-bit transfer may be followed by pulsing  $\overline{\text{ENB}}$  low with no signal on the CLK pin. This is an alternate method of transferring data to the second buffer of the R register (see Figure 17).

The bit stream needs neither address nor steering bits due to the innovative BitGrabber registers. Therefore, all bits in the stream are available to be data for the three registers. Random access of any register is provided. That is, the registers may be accessed in any sequence. Data is retained in the registers over a supply range of 4.5 to 5.5 V. The formats are shown in Figures 15, 16, and 17.

D<sub>in</sub> typically switches near 50% of V<sub>DD</sub> to maximize noise immunity. This input can be directly interfaced to CMOS devices with outputs guaranteed to switch near rail-to-rail. When interfacing to NMOS or TTL devices, either a level shifter (MC74HC14A, MC14504B) or pull-up resistor of 1 k $\Omega$  to 10 k $\Omega$  must be used. Parameters to consider when sizing the resistor are worst-case I<sub>OL</sub> of the driving device, maximum tolerable power consumption, and maximum data rate.

**Table 1. Register Access**

(MSBs are shifted in first; C0, R0, and A0 are the LSBs)

Number of Clocks	Accessed Register	Bit Nomenclature
8	C Register	C7, C6, C5, . . . , C0
16	R Register	R15, R14, R13, . . . , R0
24	A Register	A23, A22, A21, . . . , A0
Other Values $\leq$ 32	See Figure 13	
Values > 32	See Figures 22 – 25	

#### CLK Serial Data Clock Input (Pin 18)

Low-to-high transitions on CLK shift bits available at the D<sub>in</sub> pin, while high-to-low transitions shift bits from OUTPUT A (when configured as Data Out, see Pin 16).

The 24–1/2–stage shift register is static, allowing clock rates down to dc in a continuous or intermittent mode.

Eight clock cycles are required to access the C register. Sixteen clock cycles are needed for the first buffer of the R register. Twenty-four cycles are used to access the A register. See Table 1 and Figures 15, 16, and 17. The number of clocks required for cascaded devices is shown in Figures 24 through 26.

CLK typically switches near 50% of V<sub>DD</sub> and has a Schmitt-triggered input buffer. Slow CLK rise and fall times are allowed. See the last paragraph of D<sub>in</sub> for more information.

#### NOTE

To guarantee proper operation of the power-on reset (POR) circuit, the CLK pin must be held at GND (with  $\overline{\text{ENB}}$  being a don't care) or  $\overline{\text{ENB}}$  must be held at the potential of the V+ pin (with CLK being a don't care) during power-up. As an alternative, the bit sequence of Figure 13 may be used.

#### $\overline{\text{ENB}}$

##### Active Low Enable Input (Pin 17)

This pin is used to activate the serial interface to allow the transfer of data to/from the device. When  $\overline{\text{ENB}}$  is in an inactive high state, shifting is inhibited and the port is held in the initialized state. To transfer data to the device,  $\overline{\text{ENB}}$  (which must start inactive high) is taken low, a serial transfer is made via D<sub>in</sub> and CLK, and  $\overline{\text{ENB}}$  is taken back high. The low-to-high transition on  $\overline{\text{ENB}}$  transfers data to the C or A registers and first buffer of the R register, depending on the data stream length per Table 1.

#### NOTE

Transitions on  $\overline{\text{ENB}}$  must not be attempted while CLK is high. This puts the device out of synchronization with the microcontroller. Resynchronization occurs whenever  $\overline{\text{ENB}}$  is high and CLK is low.

This input is also Schmitt-triggered and switches near 50% of V<sub>DD</sub>, thereby minimizing the chance of loading erroneous data into the registers. See the last paragraph of D<sub>in</sub> for more information.

For POR information, see the note for the CLK pin.

#### OUTPUT A

##### Configurable Digital Output (Pin 16)

OUTPUT A is selectable as f<sub>R</sub>, f<sub>V</sub>, Data Out, or Port. Bits A22 and A23 in the A register control the selection; see Figure 16.

If A23 = A22 = high, OUTPUT A is configured as f<sub>R</sub>. This signal is the buffered output of the 13-stage R counter. The f<sub>R</sub> signal appears as normally low and pulses high, and can be used to verify the divide ratio of the R counter. This ratio extends from 5 to 8191 and is determined by the binary value loaded into bits R0–R12 in the R register. Also, direct access to the phase detectors via the REF<sub>in</sub> pin is allowed by choosing a divide value of 1 (see Figure 17). The maximum frequency at which the phase detectors operate is 2 MHz. Therefore, the frequency of f<sub>R</sub> should not exceed 2 MHz.

If A23 = high and A22 = low, OUTPUT A is configured as f<sub>V</sub>. This signal is the buffered output of the 12-stage N counter. The f<sub>V</sub> signal appears as normally low and pulses high, and can be used to verify the operation of the prescaler,

A counter, and N counter. The divide ratio between the  $f_{IN}$  input and the  $f_V$  signal is  $N \times 64 + A$ . N is the divide ratio of the N counter and A is the divide ratio of the A counter. These ratios are determined by bits loaded into the A register. See Figure 16. The maximum frequency at which the phase detectors operate is 2 MHz. Therefore, the frequency of  $f_V$  should not exceed 2 MHz.

If  $A23 = \text{low}$  and  $A22 = \text{high}$ , OUTPUT A is configured as Data Out. This signal is the serial output of the 24–1/2–stage shift register. The bit stream is shifted out on the high–to–low transition of the CLK input. Upon power up, OUTPUT A is automatically configured as Data Out to facilitate cascading devices.

If  $A23 = A22 = \text{low}$ , OUTPUT A is configured as Port. This signal is a general–purpose digital output which may be used as an MCU port expander. This signal is low when the Port bit (C1) of the C register is low, and high when the Port bit is high.

## OUTPUT B

### Open–Drain Digital Output (Pin 15)

This signal is a general–purpose digital output which may be used as an MCU port expander. This signal is low when the Out B bit (C0) of the C register is low. When the Out B bit is high, OUTPUT B assumes the high–impedance state. OUTPUT B may be pulled up through an external resistor or active circuitry to any voltage less than or equal to the potential of the  $V_{PD}$  pin. **Note:** the maximum voltage allowed on the  $V_{PD}$  pin is 5.5 V for the MC145191.

Upon power–up, power–on reset circuitry forces OUTPUT B to a low level.

## REFERENCE PINS

### REF<sub>IN</sub> and REF<sub>OUT</sub>

#### Reference Input and Reference Output (Pins 20 and 1)

Configurable pins for a Crystal or an External Reference. This pair of pins can be configured in one of two modes: the crystal mode or the reference mode. Bits R13, R14, and R15 in the R register control the modes as shown in Figure 17.

In crystal mode, these pins form a reference oscillator when connected to terminals of an external parallel–resonant crystal. Frequency–setting capacitors of appropriate values as recommended by the crystal supplier are connected from each of the two pins to ground (up to a maximum of 30 pF each, including stray capacitance). An external resistor of 1 M $\Omega$  to 15 M $\Omega$  is connected directly across the pins to ensure linear operation of the amplifier. The device is designed to operate with crystals up to 15 MHz; the required connections are shown in Figure 9. To turn on the oscillator, bits R15, R14, and R13 must have an octal value of one (001 in binary, respectively). This is the active–crystal mode shown in Figure 17. In this mode, the crystal oscillator runs and the R Counter divides the crystal frequency, unless the part is in standby. If the part is placed in standby via the C register, the oscillator runs, but the R counter is stopped. However, if bits R15 to R13 have a value of 0, the oscillator is stopped, which saves additional power. This is the shut–down crystal mode (shown in Figure 17) and can be engaged whether in standby or not.

In the reference mode, REF<sub>IN</sub> (Pin 20) accepts a signal up to 27 MHz from an external reference oscillator, such as a TCXO. A signal swinging from at least the  $V_{IL}$  to  $V_{IH}$  levels

listed in the Electrical Characteristics table may be directly coupled to the pin. If the signal is less than this level, ac coupling must be used as shown in Figure 8. Due to an on–board resistor which is engaged in the reference modes, an external biasing resistor tied between REF<sub>IN</sub> and REF<sub>OUT</sub> is not required.

With the reference mode, the REF<sub>OUT</sub> pin is configured as the output of a divider. As an example, if bits R15, R14, and R13 have an octal value of seven, the frequency at REF<sub>OUT</sub> is the REF<sub>IN</sub> frequency divided by 16. In addition, Figure 17 shows how to obtain ratios of eight, four, and two. A ratio of one–to–one can be obtained with an octal value of three. Upon power up, a ratio of eight is automatically initialized. The maximum frequency capability of the REF<sub>OUT</sub> pin is 10 MHz. Therefore, for REF<sub>IN</sub> frequencies above 10 MHz, the one–to–one ratio may not be used. Likewise, for REF<sub>IN</sub> frequencies above 20 MHz, the ratio must be more than two.

If REF<sub>OUT</sub> is unused, an octal value of two should be used for R15, R14, and R13 and the REF<sub>OUT</sub> pin should be floated. A value of two allows REF<sub>IN</sub> to be functional while disabling REF<sub>OUT</sub>, which minimizes dynamic power consumption and electromagnetic interference (EMI).

## LOOP PINS

### $f_{IN}$ and $\overline{f_{IN}}$

#### Frequency Inputs (Pins 11 and 10)

These pins are frequency inputs from the VCO. These pins feed the on–board RF amplifier which drives the 64/65 prescaler. These inputs may be fed differentially. However, they usually are used in a single–ended configuration (shown in Figure 7). Note that  $f_{IN}$  is driven while  $\overline{f_{IN}}$  must be tied to ground via a capacitor.

Motorola does not recommend driving  $\overline{f_{IN}}$  while terminating  $f_{IN}$  because this configuration is not tested for sensitivity. The sensitivity is dependent on the frequency as shown in the Loop Specifications table.

### PD<sub>OUT</sub>

#### Single–Ended Phase/Frequency Detector Output (Pin 6)

This is a three–state current–source/sink output for use as a loop error signal when combined with an external low–pass filter. The phase/frequency detector is characterized by a linear transfer function (no dead zone). The operation of the phase/frequency detector is described below and is shown in Figure 18.

POL bit (C7) in the C register = low (see Figure 15)

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ : current–sinking pulses from a floating state

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ : current–sourcing pulses from a floating state

Frequency and Phase of  $f_V = f_R$ : essentially a floating state; voltage at pin determined by loop filter

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ : current–sourcing pulses from a floating state

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ : current–sinking pulses from a floating state

Frequency and Phase of  $f_V = f_R$ : essentially a floating state; voltage at pin determined by loop filter

This output can be enabled, disabled, and inverted via the C register. If desired, PD<sub>OUT</sub> can be forced to the floating state by utilization of the disable feature in the C register (bit C6). This is a patented feature. Similarly, PD<sub>OUT</sub> is forced to the

floating state when the device is put into standby (STBY bit C4 = high).

The PD<sub>Out</sub> circuit is powered by V<sub>PD</sub>. The phase detector gain is controllable by bits C3, C2, and C1: gain (in amps per radian) = PD<sub>Out</sub> current divided by 2 $\pi$ .

#### $\phi_R$ and $\phi_V$ (Pins 3 and 4)

#### Double-Ended Phase/Frequency Detector Outputs

These outputs can be combined externally to generate a loop error signal. Through use of a Motorola patented technique, the detector's dead zone has been eliminated. Therefore, the phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 18.

POL bit (C7) in the C register = low (see Figure 15)

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_V$  = negative pulses,  $\phi_R$  = essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_V$  = essentially high,  $\phi_R$  = negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_R$  = negative pulses,  $\phi_V$  = essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_R$  = essentially high,  $\phi_V$  = negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

These outputs can be enabled, disabled, and interchanged via C register bits C6 or C4. This is a patented feature. Note that when disabled or in standby,  $\phi_R$  and  $\phi_V$  are forced to their rest condition (high state).

The  $\phi_R$  and  $\phi_V$  output signal swing is approximately from GND to V<sub>PD</sub>.

#### LD

#### Lock Detector Output (Pin 2)

This output is essentially at a high level with narrow low-going pulses when the loop is locked ( $f_R$  and  $f_V$  of the same phase and frequency). The output pulses low when  $f_V$  and  $f_R$  are out of phase or different frequencies. LD is the logical ANDing of  $\phi_R$  and  $\phi_V$  (see Figure 18).

This output can be enabled and disabled via the C register. This is a patented feature. Upon power up, on-chip initialization circuitry disables LD to a static low logic level to prevent a false "lock" signal. If unused, LD should be disabled and left open.

The LD output signal swing is approximately from GND to V<sub>DD</sub>.

#### Rx

#### External Resistor (Pin 8)

A resistor tied between this pin and GND, in conjunction with bits in the C register, determines the amount of current that the PD<sub>Out</sub> pin sinks and sources. When bits C2 and C3 are both set high, the maximum current is obtained at PD<sub>Out</sub>; see Tables 2 and 3 for other values of current. To achieve a maximum current of 2 mA, the resistor should be about 18 k $\Omega$  when V<sub>PD</sub> is 5.0 V. See Figure 14 if lower maximum current values are desired.

When the  $\phi_R$  and  $\phi_V$  outputs are used, the Rx pin may be floated.

## TEST POINT PINS

### TEST 1

#### Modulus Control Signal (Pin 9)

This pin may be used in conjunction with the Test 2 pin for access to the on-board 64/65 prescaler. When Test 1 is low, the prescaler divides by 65. When high, the prescaler divides by 64.

#### CAUTION

This pin is an unbuffered output and **must** be floated in an actual application. This pin must be attached to an isolated pad with no trace.

### TEST 2

#### Prescaler Output (Pin 13)

This pin may be used to access to the on-board 64/65 prescaler output.

#### CAUTION

This pin is an unbuffered output and **must** be floated in an actual application. This pin must be attached to an isolated pad with no trace.

## POWER SUPPLY PINS

### V<sub>DD</sub>

#### Positive Power Supply (Pin 14)

This pin supplies power to the main CMOS digital portion of the device. The voltage range is +4.5 to +5.5 V with respect to the GND pin.

For optimum performance, V<sub>DD</sub> should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

### V<sub>CC</sub>

#### Positive Power Supply (Pin 12)

This pin supplies power to the RF amp and 64/65 prescaler. The voltage range is +4.5 to +5.5 V with respect to the GND pin. In the standby mode, the V<sub>CC</sub> pin still draws a few milliamps from the power supply. This current drain can be eliminated with the use of transistor Q1 as shown in Figure 22.

For optimum performance, V<sub>CC</sub> should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

### V<sub>PD</sub>

#### Positive Power Supply (Pin 5)

This pin supplies power to both phase/frequency detectors A and B. The voltage applied on this pin must be no less than the potential applied to the V<sub>DD</sub> pin. The maximum voltage can be +5.5 V with respect to the GND pin.

For optimum performance, V<sub>PD</sub> should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

### GND

#### Ground (Pin 7)

Common ground.

NOTE: It may not be convenient to control the  $\overline{\text{ENB}}$  or CLK pins during power up per the Pin Descriptions. If this is the case, the part may be initialized through the serial port as shown in the figure above. The sequence is similar to accessing the registers except that the CLK must remain high at least 100 ns after  $\overline{\text{ENB}}$  is brought high. Note that 3 groups of 5 bits are needed.

**Figure 13. Initializing the PLL through the Serial Port**

**Nominal  $\text{PD}_{\text{out}}$  Spurious Current vs  $f_R$  Frequency  
(1 V <  $\text{PD}_{\text{out}}$  <  $V_{\text{PD}} - 1$  V)**

$f_R$ (kHz)	Current (RMS nA)
10	3.6
20	4.6
50	17
100	75
200	244

NOTE: For information on spurious current measurement see AN1253/D, "An Improved PLL Design Method Without  $\omega_n$  and  $\zeta$ ".

0	1	50%
1	0	75%
1	1	100%

**Nominal MC145191 PD<sub>out</sub> Source Current vs Rx Resistance**

NOTE: The MC145191 is optimized for Rx values in the 18 kΩ to 40 kΩ range. For example, to achieve 0.3 mA of output current, it is preferable to use a 30-kΩ resistor for Rx and bit settings for 25% (as shown in Table 3).

**Figure 14.**

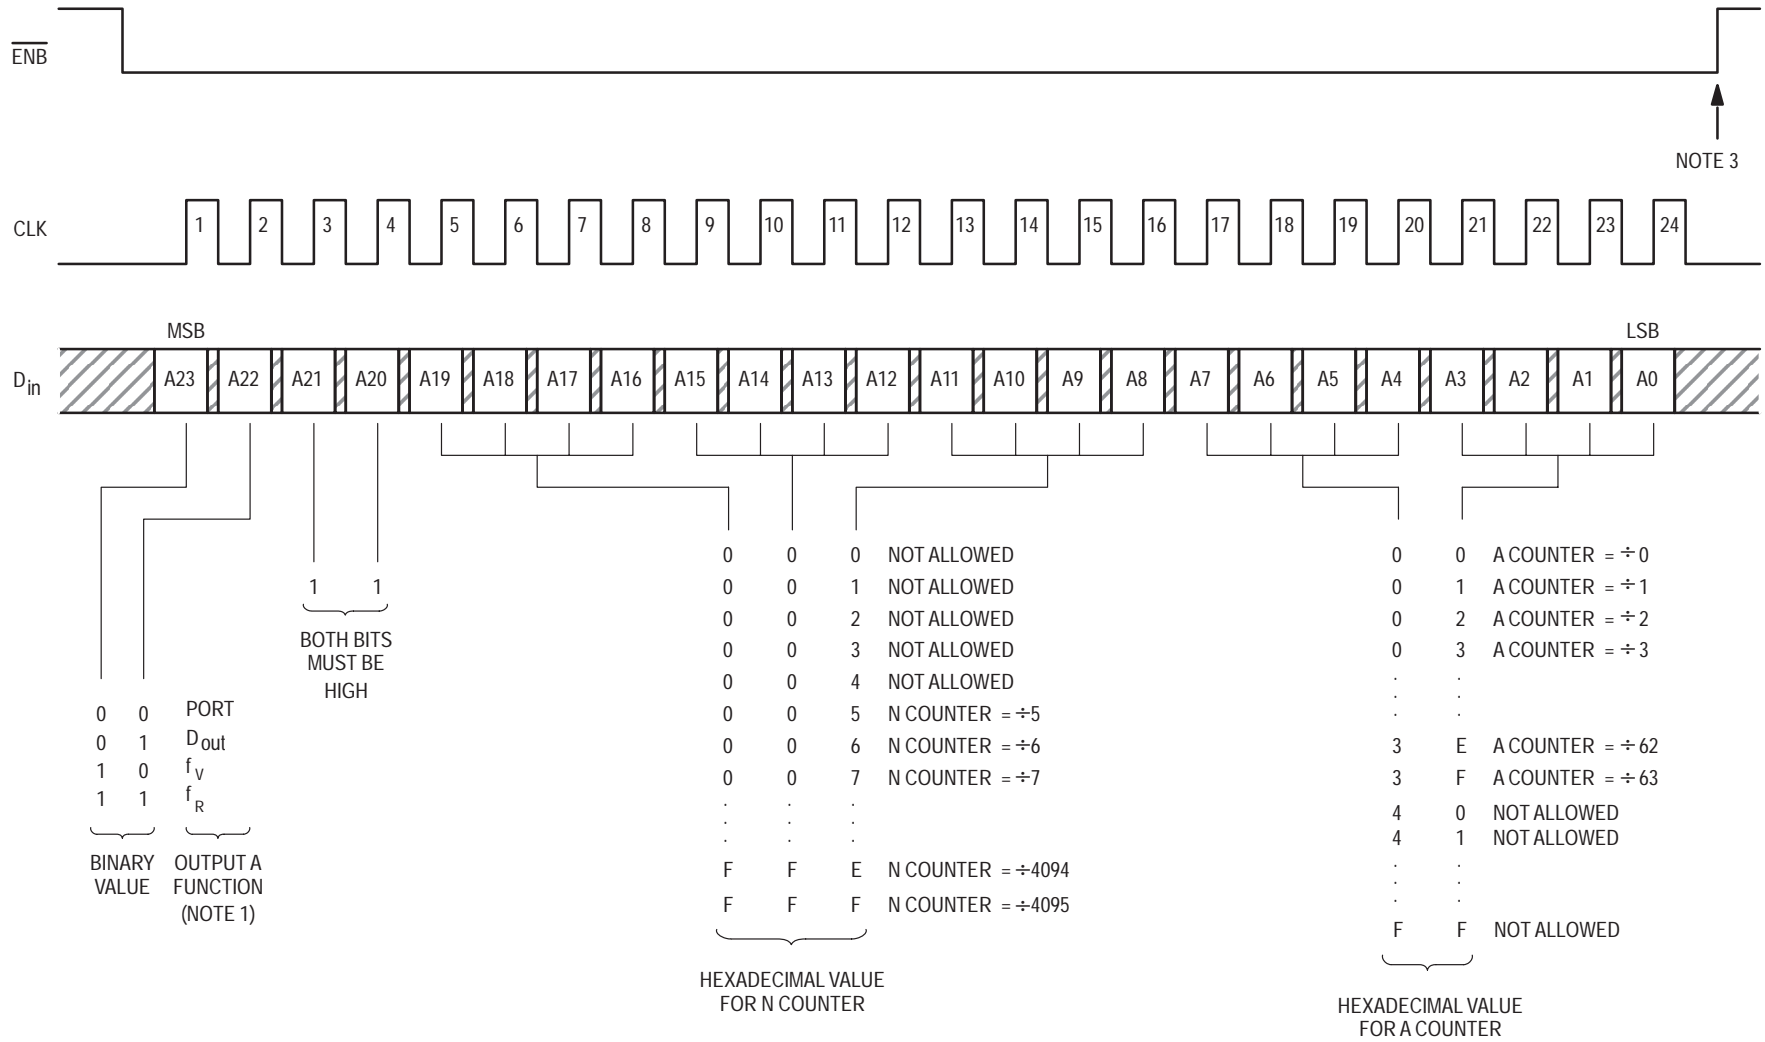

\* At this point, the new byte is transferred to the C register and stored. No other registers are affected.

- C7 — POL: Selects the output polarity of the phase/frequency detectors. When set high, this bit inverts the polarity of PD<sub>Out</sub> and interchanges the  $\phi_R$  function with  $\phi_V$  as depicted in Figure 18. Also see the phase detector output pin descriptions for more information. This bit is cleared low at power up.
- C6 — PDA/B: Selects which phase/frequency detector is to be used. When set high, enables the output of phase/frequency detector A (PD<sub>Out</sub>) and disables phase/frequency detector B by forcing  $\phi_R$  and  $\phi_V$  to the static high state. When cleared low, phase/frequency detector B is enabled ( $\phi_R$  and  $\phi_V$ ) and phase/frequency detector A is disabled with PD<sub>Out</sub> forced to the high-impedance state. This bit is cleared low at power up.
- C5 — LDE: Enables the lock detector output (LD) when set high. When the bit is cleared low, the LD output is forced to a static low level. This bit is cleared low at power up.
- C4 — STBY: When set high, places the CMOS section of device, which is powered by the V<sub>DD</sub> and V<sub>PD</sub> pins, in the standby mode for reduced power consumption: PD<sub>Out</sub> is forced to the high-impedance state,  $\phi_R$  and  $\phi_V$  are forced high, the A, N, and R counters are inhibited from counting, and the Rx current is shut off. In standby, the state of LD is determined by bit C5. C5 low forces LD low (no change). C5 high forces LD static high. During standby, data is retained in the A, R, and C registers. The condition of REF/OSC circuitry is determined by the control bits in the R register: R13, R14, and R15. However, if REF<sub>Out</sub> = static low is selected, the internal feedback resistor is disconnected and the input is inhibited when in standby; in addition, the REF<sub>In</sub> input only presents a capacitive load. NOTE: Standby does not affect the other modes of the REF/OSC circuitry.
- When C4 is reset low, the part is taken out of standby in 2 steps. First, the REF<sub>In</sub> (only in one mode) resistor is reconnected, all counters are enabled, and the Rx current is enabled. Any  $f_R$  and  $f_V$  signals are inhibited from toggling the phase/frequency detectors and lock detector. Second, when the first  $f_V$  pulse occurs, the R counter is jam loaded, and the phase/frequency and lock detectors are initialized. Immediately after the jam load, the A, N, and R counters begin counting down together. At this point, the  $f_R$  and  $f_V$  pulses are enabled to the phase and lock detectors. (Patented feature.)
- C3, C2 — I2, I1: Controls the PD<sub>Out</sub> source/sink current per Tables 2 and 3. With both bits high, the maximum current (as set by Rx per Figure 14) is available. Also, see C1 bit description.
- C1 — Port: When the OUTPUT A pin is selected as "Port" via bits A22 and A23, C1 determines the state of OUTPUT A. When C1 is set high, OUTPUT A is forced high; C1 low forces OUTPUT A low. When OUTPUT A is NOT selected as "Port," C1 controls whether the PD<sub>Out</sub> step size is 10% or 25%. (See Tables 2 and 3.) When low, steps are 10%. When high, steps are 25%. Default is 10% steps when OUTPUT A is selected as "Port." The Port bit is not affected by the standby mode.
- C0 — Out B: Determines the state of OUTPUT B. When C0 is set high, OUTPUT B is high-impedance; C0 low forces OUTPUT B low. The Out B bit is not affected by the standby mode. This bit is cleared low at power up.

**Figure 15. C Register Access and Format (8 Clock Cycles are Used)**

Figure 16. A Register Access and Format (24 Clock Cycles are Used)

NOTES:

1. A power-on initialize circuit forces the OUTPUT A function to default to Data Out.
2. The values programmed for the N counter must be greater than or equal to the values programmed for the A counter. This results in a total divide value = N x 64 + A.
3. At this point, the three new bytes are transferred to the A register. In addition, the 13 LSBs in the first buffer of the R register are transferred to the R register's second buffer. Thus, the R, N, and A counters can be presented new divide ratios at the same time. The first buffer of the R register is not affected. The C register is not affected.

**NOTES:**

1. Bits R15 through R13 control the configurable “OSC or 4–stage divider” block (see Block Diagram).
2. Bits R12 through R0 control the “13–stage R counter” block (see Block Diagram).
3. A power–on initialize circuit forces a default REF<sub>in</sub> to REF<sub>out</sub> ratio of eight.
4. At this point, bits R13, R14, and R15 are stored and sent to the “OSC or 4–Stage Divider” block in the Block Diagram. Bits R0 through R12 are loaded into the first buffer in the double–buffered section of the R register. Therefore, the R counter divide ratio is not altered yet and retains the previous ratio loaded. The C and A registers are not affected.
5. At this point, bits R0 through R12 are transferred to the second buffer of the R register. The R counter begins dividing by the new ratio after completing the rest of the present count cycle. CLK must be low during the ENB pulse, as shown. Also, see note 3 of Figure 16 for an alternate method of loading the second buffer in the R register. The C and A registers are not affected. The first buffer of the R register is not affected.
6. Allows direct access to reference input of phase/frequency detectors.

**Figure 17. R Register Access and Format (16 Clock Cycles Are Used)**

V<sub>H</sub> = High voltage level

V<sub>L</sub> = Low voltage level

\*At this point, when both f<sub>R</sub> and f<sub>V</sub> are in phase, the output source and sink circuits are turned on for a short interval.

NOTE: The PD<sub>out</sub> either sources or sinks current during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low-pass filter capacitor. PD<sub>out</sub>, φ<sub>R</sub>, and φ<sub>V</sub> are shown with the polarity bit (POL) = low; see Figure 14 for POL.

**Figure 18. Phase/Frequency Detectors and Lock Detector Output Waveforms**

## DESIGN CONSIDERATIONS

### CRYSTAL OSCILLATOR CONSIDERATIONS

The following options may be considered to provide a reference frequency to Motorola's CMOS frequency synthesizers.

#### Use of a Hybrid Crystal Oscillator

Commercially available temperature-compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide very stable reference frequencies. An oscillator capable of CMOS logic levels at the output may be direct or dc coupled to REF<sub>in</sub>. If the oscillator does not have CMOS logic levels on the outputs, capacitive or ac coupling to REF<sub>in</sub> may be used (see Figure 8).

For additional information about TCXOs and data clock oscillators, please consult the latest version of the *eem Electronic Engineers Master Catalog*, the *Gold Book*, or similar publications.

#### Design an Off-Chip Reference

The user may design an off-chip crystal oscillator using discrete transistors or ICs specifically developed for crystal oscillator applications, such as the MC12061 MECL device. The reference signal from the MECL device is ac coupled to REF<sub>in</sub> (see Figure 8). For large amplitude signals (standard CMOS logic levels), dc coupling may be used.

#### Use of the On-Chip Oscillator Circuitry

The on-chip amplifier (a digital inverter) along with an appropriate crystal may be used to provide a reference source frequency. A fundamental mode crystal, parallel resonant at

the desired operating frequency, should be connected as shown in Figure 19.

The crystal should be specified for a loading capacitance (C<sub>L</sub>) which does not exceed approximately 20 pF when used at the highest operating frequency of 15 MHz. Assuming R1 = 0 Ω, the shunt load capacitance (C<sub>L</sub>) presented across the crystal can be estimated to be:

$$C_L = \frac{C_{in}C_{out}}{C_{in}+C_{out}} + C_a + C_{stray} + \frac{C_1 \cdot C_2}{C_1 + C_2}$$

where

C<sub>in</sub> = 5 pF (see Figure 20)

C<sub>out</sub> = 6 pF (see Figure 20)

C<sub>a</sub> = 1 pF (see Figure 20)

C1 and C2 = external capacitors (see Figure 19)

C<sub>stray</sub> = the total equivalent external circuit stray capacitance appearing across the crystal terminals

The oscillator can be "trimmed" on-frequency by making a portion or all of C1 variable. The crystal and associated components must be located as close as possible to the REF<sub>in</sub> and REF<sub>out</sub> pins to minimize distortion, stray capacitance, stray inductance, and startup stabilization time. Circuit stray capacitance can also be handled by adding the appropriate stray value to the values for C<sub>in</sub> and C<sub>out</sub>. For this approach, the term C<sub>stray</sub> becomes 0 in the above expression for C<sub>L</sub>.

Power is dissipated in the effective series resistance of the crystal, R<sub>e</sub>, in Figure 21. The maximum drive level specified by the crystal manufacturer represents the maximum stress that the crystal can withstand without damage or excessive shift in operating frequency. R1 in Figure 19 limits the drive level. The use of R1 is not necessary in most cases.

To verify that the maximum dc supply voltage does not cause the crystal to be overdriven, monitor the output

frequency ( $f_R$ ) at OUTPUT A as a function of supply voltage. ( $REF_{out}$  is not used because loading impacts the oscillator.) The frequency should increase very slightly as the dc supply voltage is increased. An overdriven crystal decreases in frequency or becomes unstable with an increase in supply voltage. The operating supply voltage must be reduced or R1 must be increased in value if the overdriven condition exists. The user should note that the oscillator start-up time is proportional to the value of R1.

Through the process of supplying crystals for use with CMOS inverters, many crystal manufacturers have developed expertise in CMOS oscillator design with crystals. Discussions with such manufacturers can prove very helpful (see Table 4).

## PHASE-LOCKED LOOP—LOW PASS FILTER DESIGN

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC}}$$

$$\zeta = \frac{R}{2} \sqrt{\frac{K_\phi K_{VCO} C}{N}} = \frac{\omega_n RC}{2}$$

$$Z(s) = \frac{1 + sRC}{sC}$$

### NOTE:

For (A), using  $K_\phi$  in amps per radian with the filter's impedance transfer function,  $Z(s)$ , maintains units of volts per radian for the detector/filter combination. Additional sideband filtering can be accomplished by adding a capacitor  $C'$  across  $R$ . The corner  $\omega_c = 1/RC'$  should be chosen such that  $\omega_n$  is not significantly affected.

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NCR_1}}$$

$$\zeta = \frac{\omega_n R_2 C}{2}$$

ASSUMING GAIN A IS VERY LARGE, THEN:

$$F(s) = \frac{R_2 s C + 1}{R_1 s C}$$

### NOTE:

For (B),  $R_1$  is frequently split into two series resistors; each resistor is equal to  $R_1$  divided by 2. A capacitor  $C_C$  is then placed from the midpoint to ground to further filter the error pulses. The value of  $C_C$  should be such that the corner frequency of this network does not significantly affect  $\omega_n$ .

\* The  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. The  $\phi_R$  and  $\phi_V$  outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp used in the combiner/loop filter.

### DEFINITIONS:

$N$  = Total Division Ratio in Feedback Loop

$K_\phi$  (Phase Detector Gain) =  $I_{PD_{out}}/2\pi$  amps per radian for  $PD_{out}$

$K_\phi$  (Phase Detector Gain) =  $V_{PD}/2\pi$  volts per radian for  $\phi_V$  and  $\phi_R$

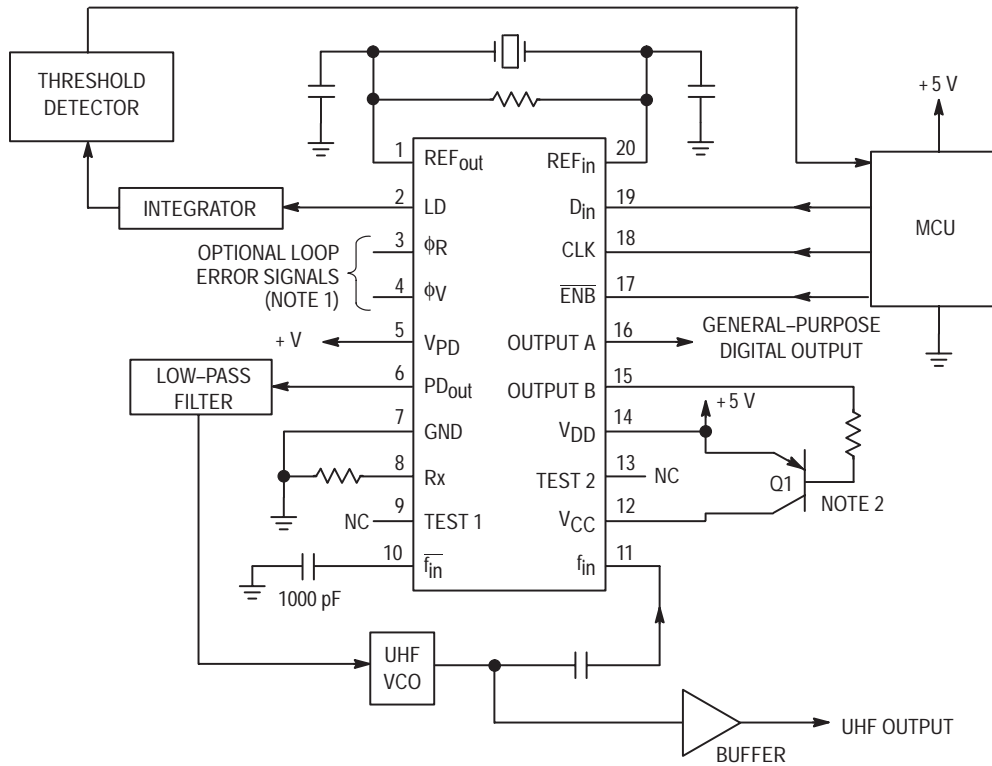

$$K_{VCO} \text{ (VCO Transfer Function)} = \frac{2\pi \Delta f_{VCO}}{\Delta V_{VCO}} \text{ radians per volt}$$

For a nominal design starting point, the user might consider a damping factor  $\zeta \approx 0.7$  and a natural loop frequency  $\omega_n \approx (2\pi f_R/50)$  where  $f_R$  is the frequency at the phase detector input. Larger  $\omega_n$  values result in faster loop lock times and, for similar sideband filtering, higher  $f_R$ -related VCO sidebands.

Either loop filter (A) or (B) is frequently followed by additional sideband filtering to further attenuate  $f_R$ -related VCO sidebands. This additional filtering may be active or passive.

NOTES:

1. When used, the  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information.
2. Transistor Q1 is required only if the standby feature is needed. Q1 permits the bipolar section of the device to be shut down via use of the general-purpose digital pin, OUTPUT B. If the standby feature is not needed, tie Pin 12 directly to the power supply.
3. For optimum performance, bypass the  $V_{CC}$ ,  $V_{DD}$ , and  $V_{PD}$  pins to GND with low-inductance capacitors.
4. The R counter is programmed for a divide value =  $REF_{in}/f_R$ . Typically,  $f_R$  is the tuning resolution required for the VCO. Also, the VCO frequency divided by  $f_R = N_T = N \times 64 + A$ ; this determines the values (N, A) that must be programmed into the N and A counters, respectively.

Figure 22. Example Application

NOTE: See related Figures 24 through 26; these bit streams apply to the MC145191 and MC145201.

Figure 23. Cascading Two Devices

Figure 26. Accessing the R Registers of Two Cascaded Devices

NOTES APPLICABLE TO EACH DEVICE:

1. At this point, bits R13, R14, and R15 are stored and sent to the "OSC or 4-Stage Divider" block in the Block Diagram. Bits R0 through R12 are loaded into the first buffer in the double-buffered section of the R register. Therefore, the R counter divide ratio is not altered yet and retains the previous ratio loaded. The C and A registers are not affected.
2. At this point, the bits R0 through R12 are transferred to the second buffer of the R register. The R counter begins dividing by the new ratio after completing the rest of the present count cycle. CLK must be low during the ENB pulse, as shown. Also, see note of Figure 25 for an alternate method of loading the second buffer in the R register. The C and A registers are not affected. The first buffer of the R register is not affected.

# Low-Voltage 1.1 GHz PLL Frequency Synthesizer

## Includes On-Board 64/65 Prescaler

The MC145192 is a low-voltage single-package synthesizer with serial interface capable of direct usage up to 1.1 GHz. A special architecture makes this PLL very easy to program because a byte-oriented format is utilized. Due to the patented BitGrabber™ registers, no address/steering bits are required for *random access* of the three registers. Thus, tuning can be accomplished via a 3-byte serial transfer to the 24-bit A register. The interface is both SPI and MICROWIRE™ compatible.

The device features a single-ended current source/sink phase detector A output and a double-ended phase detector B output. Both phase detectors have linear transfer functions (no dead zones). The maximum current of the single-ended phase detector output is determined by an external resistor tied from the Rx pin to ground. This current can be varied via the serial port.

The MC145192 phase/frequency detector B  $\phi_R$  and  $\phi_V$  outputs can be powered from 2.7 to 5.5 V. This is optimized for 3.0 V systems. The phase/frequency detector A PD<sub>OUT</sub> output must be powered from 4.5 to 5.5 V, and is optimized for a 5 volt supply.

This part includes a differential RF input which may be operated in a single-ended mode. Also featured are on-board support of an external crystal and a programmable reference output. The R, A, and N counters are fully programmable. The C register (configuration register) allows the part to be configured to meet various applications. A patented feature allows the C register to shut off unused outputs, thereby minimizing system noise and interference.

In order to have consistent lock times and prevent erroneous data from being loaded into the counters, on-board circuitry synchronizes the update of the A register if the A or N counters are loading. Similarly, an update of the R register is synchronized if the R counter is loading.

The double-buffered R register allows new divide ratios to be presented to the three counters (R, A, and N) simultaneously.

- Maximum Operating Frequency: 1100 MHz @  $V_{in} = 200$  mV p-p
- Operating Supply Current: 6 mA Nominal at 2.7 V
- Operating Supply Voltage Range ( $V_{DD}$  and  $V_{CC}$  Pins): 2.7 to 5.0 V
- Operating Supply Voltage Range of Phase Frequency Detector A ( $V_{PD}$  Pin) = 4.5 to 5.5 V
- Operating Supply Voltage Range of Phase Detector B ( $V_{PD}$  Pin) = 2.7 to 5.5 V
- Current Source/Sink Phase Detector Output Capability: 2 mA Maximum
- Gain of Current Source/Sink Phase/Frequency Detector Controllable via Serial Port
- Operating Temperature Range: -40° to 85°C
- R Counter Division Range: (1 and) 5 to 8191
- N Counter Division Range: 5 to 4095
- A Counter Division Range: 0 to 63
- Dual-Modulus Capability Provides Total Division up to 262,143
- High-Speed Serial Interface: 2 Megabits per Second
- Output A Pin, When Configured as Data Out, Permits Cascading of Devices
- Two General-Purpose Digital Outputs — Output A: Totem-Pole (Push-Pull) with Four Output Modes  
Output B: Open-Drain
- Power-Saving Standby Feature with Patented Orderly Recovery for Minimizing Lock Times, Standby Current: 30  $\mu$ A

## BLOCK DIAGRAM

### MAXIMUM RATINGS\* (Voltages Referenced to GND, unless otherwise stated)

Symbol	Parameter	Value	Unit
$V_{CC}$ , $V_{DD}$	DC Supply Voltage (Pins 12 and 14)	- 0.5 to + 6.0	V
$V_{PD}$	DC Supply Voltage (Pin 5)	$V_{DD} - 0.5$ to + 6.0	V
$V_{in}$	DC Input Voltage	- 0.5 to $V_{DD} + 0.5$	V
$V_{out}$	DC Output Voltage, except Output B, $PD_{out}$ , $\phi_R$ , $\phi_V$ Output B, $PD_{out}$ , $\phi_R$ , $\phi_V$	- 0.5 to $V_{DD} + 0.5$ - 0.5 to $V_{PD} + 0.5$	V
$I_{in}$ , $I_{PD}$	DC Input Current, per Pin (Includes $V_{PD}$ )	$\pm 10$	mA
$I_{out}$	DC Output Current, per Pin	$\pm 20$	mA
$I_{DD}$	DC Supply Current, $V_{DD}$ and GND Pins	$\pm 30$	mA
$P_D$	Power Dissipation, per Package	300	mW
$T_{stg}$	Storage Temperature	- 65 to + 150	$^{\circ}C$
$T_L$	Lead Temperature, 1 mm from Case for 10 Seconds	260	$^{\circ}C$

\* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit.

**ELECTRICAL CHARACTERISTICS** ( $V_{DD} = V_{CC} = 2.7$  to  $5.0$  V, Voltages Referenced to GND,  $T_A = -40^\circ$  to  $85^\circ\text{C}$ , unless otherwise stated; Phase/Frequency Detector A  $V_{PD} = 4.5$  to  $5.5$  V with  $V_{DD} \leq V_{PD}$ ; Phase/Frequency Detector B  $V_{PD} = 2.7$  to  $5.5$  V with  $V_{DD} \leq V_{PD}$ )

Symbol	Parameter	Test Condition	Guaranteed Limit	Unit
$V_{IL}$	Maximum Low-Level Input Voltage (Data In, Clock, $\overline{\text{Enable}}$ , $\text{REF}_{in}$ )	Device in Reference Mode, DC Coupled	$0.2 \times V_{DD}$	V
$V_{IH}$	Minimum High-Level Input Voltage (Data In, Clock, $\overline{\text{Enable}}$ , $\text{REF}_{in}$ )	Device in Reference Mode, DC Coupled	$0.8 \times V_{DD}$	V
$V_{Hys}$	Minimum Hysteresis Voltage (Clock, Enable)	$V_{DD} = 2.7$ V $V_{DD} = 5.0$ V	100 300	mV
$V_{OL}$	Maximum Low-Level Output Voltage ( $\text{REF}_{out}$ , Output A)	$I_{out} = 20 \mu\text{A}$ , Device in Reference Mode	0.1	V
$V_{OH}$	Minimum High-Level Output Voltage ( $\text{REF}_{out}$ , Output A)	$I_{out} = -20 \mu\text{A}$ , Device in Reference Mode	$V_{DD} - 0.1$	V
$I_{OL}$	Minimum Low-Level Output Current ( $\text{REF}_{out}$ , LD)	$V_{out} = 0.4$ V	0.25	mA
$I_{OL}$	Minimum Low-Level Output Current ( $\phi_R$ , $\phi_V$ )	$V_{out} = 0.4$ V $V_{DD}, V_{PD} = 2.7$ V	0.36	mA
$I_{OL}$	Minimum Low-Level Output Current (Output A)	$V_{out} = 0.4$ V	0.6	mA
$I_{OL}$	Minimum Low-Level Output Current (Output B)	$V_{out} = 0.4$ V	1.0	mA
$I_{OH}$	Minimum High-Level Output Current ( $\text{REF}_{out}$ , LD)	$V_{out} = V_{DD} - 0.4$ V	-0.25	mA
$I_{OH}$	Minimum High-Level Output Current ( $\phi_R$ , $\phi_V$ )	$V_{out} = V_{PD} - 0.4$ V $V_{DD}, V_{PD} = 2.7$ V	-0.36	mA
$I_{OH}$	Minimum High-Level Output Current (Output A Only)	$V_{out} = V_{DD} - 0.4$ V	-0.35	mA
$I_{in}$	Maximum Input Leakage Current (Data In, Clock, $\overline{\text{Enable}}$ , $\text{REF}_{in}$ )	$V_{in} = V_{DD}$ or GND, Device in XTAL Mode	$\pm 1.0$	$\mu\text{A}$
$I_{in}$	Maximum Input Current ( $\text{REF}_{in}$ )	$V_{in} = V_{DD}$ or GND, Device in Reference Mode	$\pm 150$	$\mu\text{A}$
$I_{OZ}$	Maximum Output Leakage Current ( $\text{PD}_{out}$ ) (Output B)	$V_{out} = V_{PD} - 0.5$ V or $0.5$ V, Output in High-Impedance State	$\pm 200$	nA
		Output in High-Impedance State	$\pm 10$	$\mu\text{A}$
$I_{STBY}$	Maximum Standby Supply Current ( $V_{DD} + V_{PD}$ Pins)	$V_{in} = V_{DD}$ or GND; Outputs Open; Device in Standby Mode, Shut-Down Crystal Mode or $\text{REF}_{out}$ -Static-Low Reference Mode; Output B Controlling $V_{CC}$ per Figure 22	30	$\mu\text{A}$
$I_{PD}$	Maximum Phase Detector Quiescent Current ( $V_{PD}$ Pin)	Bit C6 = High Which Selects Phase Detector A, $\text{PD}_{out} = \text{Open}$ , $\text{PD}_{out} = \text{Static Low or High}$ , Bit C4 = Low Which is NOT Standby, $I_{RX} = 113 \mu\text{A}$ , $V_{PD} = 5.5$ V	600	$\mu\text{A}$
		Bit C6 = Low Which Selects Phase Detector B, $\phi_R$ and $\phi_V = \text{Open}$ , $\phi_R$ and $\phi_V = \text{Static Low or High}$ , Bit C4 = Low Which is NOT Standby	30	
$I_T$	Total Operating Supply Current ( $V_{DD} + V_{PD} + V_{CC}$ Pins)	$f_{in} = 1.1$ GHz; $\text{REF}_{in} = 13$ MHz @ $1$ V p-p; Output A = Inactive and No Connect; $V_{DD} = V_{CC}$ , $\text{REF}_{out}$ , $\phi_V$ , $\phi_R$ , $\text{PD}_{out}$ , LD = No Connect; Data In, $\overline{\text{Enable}}$ , Clock = $V_{DD}$ or GND, Phase Detector A Off	*	mA

\* The nominal values are:

6 mA at  $V_{DD} = 2.7$  V and  $V_{PD} = 2.7$  V

9 mA at  $V_{DD} = 5.0$  V and  $V_{PD} = 5.5$  V

These are not guaranteed limits.

## ANALOG CHARACTERISTICS — CURRENT SOURCE/SINK OUTPUT — $PD_{out}$

( $I_{out} \leq 2 \text{ mA}$ ,  $V_{DD} = V_{CC} = 2.7 \text{ to } 5.0 \text{ V}$ , Voltages Referenced to GND,  $V_{DD} = V_{CC} \leq V_{PD}$ )

Parameter	Test Condition	$V_{PD}$	Guaranteed Limit	Unit
Maximum Source Current Variation Part-to-Part	$V_{out} = 0.5 \times V_{PD}$	4.5	$\pm 20$	%
		5.5	$\pm 20$	
Maximum Sink-versus-Source Mismatch (Note 3)	$V_{out} = 0.5 \times V_{PD}$	4.5	12	%
		5.5	12	
Output Voltage Range (Note 3)	$I_{out} \text{ variation} \leq 20\%$	4.5	0.5 to 4.0	V
		5.5	0.5 to 5.0	

### NOTES:

- Percentages calculated using the following formula: (Maximum Value – Minimum Value) / Maximum Value.
- See Rx Pin Description for external resistor values.
- This parameter is guaranteed for a given temperature within  $-40^\circ$  to  $85^\circ\text{C}$ .

## AC INTERFACE CHARACTERISTICS

( $V_{DD} = V_{CC} = 2.7 \text{ to } 5.0 \text{ V}$ ,  $T_A = -40^\circ$  to  $85^\circ\text{C}$ ,  $C_L = 50 \text{ pF}$ , Input  $t_r = t_f = 10 \text{ ns}$ ,  $V_{PD} = 2.7 \text{ to } 5.5 \text{ V}$  with  $V_{DD} \leq V_{PD}$ )

Symbol	Parameter	Guaranteed Limit	Unit
$f_{clk}$	Serial Data Clock Frequency (Figure 1) NOTE: Refer to Clock $t_w$ below	dc to 2.0	MHz
$t_{PLH}$ , $t_{PHL}$	Maximum Propagation Delay, Clock to Output A (Selected as Data Out) (Figures 1 and 5)	200	ns
$t_{PLH}$ , $t_{PHL}$	Maximum Propagation Delay, $\overline{\text{Enable}}$ to Output A (Selected as Port) (Figures 2 and 5)	200	ns
$t_{PZL}$ , $t_{PLZ}$	Maximum Propagation Delay, $\overline{\text{Enable}}$ to Output B (Figures 2 and 6)	200	ns
$t_{TLH}$ , $t_{THL}$	Maximum Output Transition Time, Output A and Output B; $t_{THL}$ only, on Output B (Figures 1, 5, and 6)	200	ns
$C_{in}$	Maximum Input Capacitance — Data In, Clock, $\overline{\text{Enable}}$	10	pF

## TIMING REQUIREMENTS ( $V_{DD} = V_{CC} = 2.7 \text{ to } 5.0 \text{ V}$ , $T_A = -40^\circ$ to $85^\circ\text{C}$ , Input $t_r = t_f = 10 \text{ ns}$ unless otherwise indicated)

Symbol	Parameter	Guaranteed Limit	Unit
$t_{su}$ , $t_h$	Minimum Setup and Hold Times, Data In versus Clock (Figure 3)	50	ns
$t_{su}$ , $t_h$ , $t_{rec}$	Minimum Setup, Hold and Recovery Times, $\overline{\text{Enable}}$ versus Clock (Figure 4)	100	ns
$t_w$	Minimum Pulse Width, $\overline{\text{Enable}}$ (Figure 4)	*	cycles
$t_w$	Minimum Pulse Width, Clock (Figure 1)	250	ns
$t_r$ , $t_f$	Maximum Input Rise and Fall Times, Clock (Figure 1)	100	$\mu\text{s}$

\* The minimum limit is 3  $REF_{in}$  cycles or 195  $f_{in}$  cycles, whichever is greater.

## PIN DESCRIPTIONS

### DIGITAL INTERFACE PINS

#### Data In (Pin 19)

Serial Data Input. The bit stream begins with the MSB and is shifted in on the low-to-high transition of Clock. The bit pattern is 1 byte (8 bits) long to access the C or configuration register, 2 bytes (16 bits) to access the first buffer of the R register, or 3 bytes (24 bits) to access the A register (see Table 1). The values in the C, R, and A registers do not change during shifting because the transfer of data to the registers is controlled by  $\overline{\text{Enable}}$ .

#### CAUTION

The value programmed for the N-counter must be greater than or equal to the value of the A-counter.

The 13 LSBs of the R register are double-buffered. As indicated above, data is latched into the first buffer on a 16-bit transfer. (The 3 MSBs are not double-buffered and have an immediate effect after a 16-bit transfer.) The second buffer of the R register contains the 13 bits for the R counter. This second buffer is loaded with the contents of the first buffer when the A register is loaded (a 24-bit transfer). This allows presenting new values to the R, A, and N counters simultaneously. If this is not required, then the 16-bit transfer may be followed by pulsing  $\overline{\text{Enable}}$  low with no signal on the Clock pin. This is an alternate method of transferring data to the second buffer of the R register. See Figure 17.

The bit stream needs neither address nor steering bits due to the innovative BitGrabber registers. Therefore, all bits in the stream are available to be data for the three registers. Random access of any register is provided. That is, the registers may be accessed in any sequence. Data is retained in the registers over a supply range of 2.7 to 5.0 V. The formats are shown in Figures 15, 16, and 17.

Data In typically switches near 50% of  $V_{DD}$  to maximize noise immunity. This input can be directly interfaced to CMOS devices with outputs guaranteed to switch near rail-to-rail. When interfacing to NMOS or TTL devices, either a level shifter (MC74HC14A, MC14504B) or pull-up resistor of 1 k $\Omega$  to 10 k $\Omega$  must be used. Parameters to consider when sizing the resistor are worst-case  $I_{OL}$  of the driving device, maximum tolerable power consumption, and maximum data rate.

**Table 1. Register Access**

(MSBs are shifted in first, C0, R0, and A0 are the LSBs)

Number of Clocks	Accessed Register	Bit Nomenclature
8	C Register	C7, C6, C5, . . . , C0
16	R Register	R15, R14, R13, . . . , R0
24	A Register	A23, A22, A21, . . . , A0
Other Values $\leq$ 32	Not Allowed	
Values $>$ 32	See Figures 24 to 27	

#### Clock (Pin 18)

Serial Data Clock Input. Low-to-high transitions on Clock shift bits available at the Data pin, while high-to-low transitions shift bits from Output A (when configured as Data Out, see Pin 16). The 24-1/2-stage shift register is static,

allowing clock rates down to dc in a continuous or intermittent mode.

Eight clock cycles are required to access the C register. Sixteen clock cycles are needed for the first buffer of the R register. Twenty-four cycles are used to access the A register. See Table 1 and Figures 15, 16, and 17. The number of clocks required for cascaded devices is shown in Figures 25 through 27.

Clock typically switches near 50% of  $V_{DD}$  and has a Schmitt-triggered input buffer. Slow Clock rise and fall times are allowed. See the last paragraph of **Data In** for more information.

#### NOTE

To guarantee proper operation of the power-on reset (POR) circuit, the Clock pin must be held at GND (with  $\overline{\text{Enable}}$  being a don't care) or  $\overline{\text{Enable}}$  must be held at the potential of the V+ pin (with Clock being a don't care) during power-up. As an alternative, the bit sequence of Figure 18 may be used.

#### $\overline{\text{Enable}}$ (Pin 17)

Active-Low Enable Input. This pin is used to activate the serial interface to allow the transfer of data to/from the device. When  $\overline{\text{Enable}}$  is in an inactive high state, shifting is inhibited and the port is held in the initialized state. To transfer data to the device,  $\overline{\text{Enable}}$  (which must start inactive high) is taken low, a serial transfer is made via Data In and Clock, and  $\overline{\text{Enable}}$  is taken back high. The low-to-high transition on  $\overline{\text{Enable}}$  transfers data to the C or A registers and first buffer of the R register, depending on the data stream length per Table 1.

#### NOTE

Transitions on  $\overline{\text{Enable}}$  must not be attempted while Clock is high. This will put the device out of synchronization with the microcontroller. Resynchronization occurs when  $\overline{\text{Enable}}$  is high and Clock is low.

This input is also Schmitt-triggered and switches near 50% of  $V_{DD}$ , thereby minimizing the chance of loading erroneous data into the registers. See the last paragraph of **Data In** for more information.

For POR information, see the note for the **Clock pin**.

#### Output A (Pin 16)

Configurable Digital Output. Output A is selectable as  $f_R$ ,  $f_V$ , Data Out, or Port. Bits A22 and A23 in the A register control the selection; see Figure 16.

If A23 = A22 = high, Output A is configured as  $f_R$ . This signal is the buffered output of the 13-stage R counter. The  $f_R$  signal appears as normally low and pulses high. The  $f_R$  signal can be used to verify the divide ratio of the R counter. This ratio extends from 5 to 8191 and is determined by the binary value loaded into bits R0 through R12 in the R register. Also, direct access to the phase detectors via the  $\text{REF}_{in}$  pin is allowed by choosing a divide value of one. See Figure 17. The maximum frequency at which the phase detectors operate is 1 MHz. Therefore, the frequency of  $f_R$  should not exceed 1 MHz.

If A23 = high and A22 = low, Output A is configured as  $f_N$ . This signal is the buffered output of the 12-stage N counter.

The  $f_y$  signal appears as normally low and pulses high. The  $f_y$  signal can be used to verify the operation of the prescaler, A counter, and N counter. The divide ratio between the  $f_{in}$  input and the  $f_y$  signal is  $N \times 64 + A$ .  $N$  is the divide ratio of the N counter and  $A$  is the divide ratio of the A counter. These ratios are determined by bits loaded into the A register. See Figure 16. The maximum frequency at which the phase detectors operate is 1 MHz. Therefore, the frequency of  $f_y$  should not exceed 1 MHz.

If  $A_{23} = \text{low}$  and  $A_{22} = \text{high}$ , Output A is configured as Data Out. This signal is the serial output of the 24-1/2-stage shift register. The bit stream is shifted out on the high-to-low transition of the Clock input. Upon power up, Output A is automatically configured as Data Out to facilitate cascading devices.

If  $A_{23} = A_{22} = \text{low}$ , Output A is configured as Port. This signal is a general-purpose digital output which may be used as an MCU port expander. This signal is low when the Port bit (C1) of the C register is low, and high when the Port bit is high.

### Output B (Pin 15)

Open-Drain Digital Output. This signal is a general-purpose digital output which may be used as an MCU port expander. This signal is low when the Out B bit (C0) of the C register is low. When the Out B bit is high, Output B assumes the high-impedance state. Output B may be pulled up through an external resistor or active circuitry to any voltage less than or equal to the potential of the  $V_{PD}$  pin. Note: the maximum voltage allowed on the  $V_{PD}$  pin is 5.5 V for the MC145192.

Upon power-up, power-on reset circuitry forces Output B to a low level.

## REFERENCE PINS

### REF<sub>in</sub> and REF<sub>out</sub> (Pins 20 and 1)

Configurable Pins for a Crystal or an External Reference. This pair of pins can be configured in one of two modes: the crystal mode or the reference mode. Bits R13, R14, and R15 in the R register control the modes as shown in Figure 17.

In crystal mode, these pins form a reference oscillator when connected to terminals of an external parallel-resonant crystal. Frequency-setting capacitors of appropriate values as recommended by the crystal supplier are connected from each of the two pins to ground (up to a maximum of 30 pF each, including stray capacitance). An external resistor of 1 M $\Omega$  to 15 M $\Omega$  is connected directly across the pins to ensure linear operation of the amplifier. The device is designed to operate with crystals up to 10 MHz; the required connections are shown in Figure 9. To turn on the oscillator, bits R15, R14, and R13 must have an octal value of one (001 in binary). This is the active-crystal mode shown in Figure 17. In this mode, the crystal oscillator runs and the R Counter divides the crystal frequency, unless the part is in standby. If the part is placed in standby via the C register, the oscillator runs, but the R counter is stopped. However, if bits R15 to R13 have a value of 0, the oscillator is stopped, which saves additional power. This is the shut-down crystal mode shown in Figure 17, and can be engaged whether in standby or not.

In the reference mode, REF<sub>in</sub> (Pin 20) accepts a signal up to 20 MHz from an external reference oscillator, such as a TCXO. A signal swinging from at least the  $V_{LL}$  to  $V_{IH}$  levels

listed in the Electrical Characteristics table may be directly coupled to the pin. If the signal is less than this level, ac coupling must be used as shown in Figure 8. The ac-coupled signal must be at least 400 mV p-p. Due to an on-board resistor which is engaged in the reference modes, an external biasing resistor tied between REF<sub>in</sub> and REF<sub>out</sub> is not required.

With the reference mode, the REF<sub>out</sub> pin is configured as the output of a divider. As an example, if bits R15, R14, and R13 have an octal value of seven, the frequency at REF<sub>out</sub> is the REF<sub>in</sub> frequency divided by 16. In addition, Figure 17 shows how to obtain ratios of eight, four, and two. A ratio of one-to-one can be obtained with an octal value of three. Upon power up, a ratio of eight is automatically initialized. The maximum frequency capability of the REF<sub>out</sub> pin is 5 MHz for  $V_{DD}$  to  $V_{SS}$  swing. Therefore, for REF<sub>in</sub> frequencies above 5 MHz, the one-to-one ratio may not be used for large signal swing requirements. Likewise, for REF<sub>in</sub> frequencies above 10 MHz, the ratio must be more than two.

If REF<sub>out</sub> is unused, an octal value of two should be used for R15, R14, and R13 and the REF<sub>out</sub> pin should be floated. A value of two allows REF<sub>in</sub> to be functional while disabling REF<sub>out</sub>, which minimizes dynamic power consumption and electromagnetic interference (EMI).

## LOOP PINS

### $f_{in}$ and $\overline{f_{in}}$ (Pins 11 and 10)

Frequency Input from the VCO. These pins feed the on-board RF amplifier which drives the 64/65 prescaler. These inputs may be fed differentially. However, they are usually used in a single-ended configuration as shown in Figure 7. Note that  $f_{in}$  is driven while  $\overline{f_{in}}$  must be tied to ground via a capacitor.

Motorola does not recommend driving  $\overline{f_{in}}$  while terminating  $f_{in}$  because this configuration is not tested for sensitivity. The sensitivity is dependent on the frequency as shown in the Loop Specifications table.

### PD<sub>out</sub> (Pin 6)

Single-Ended Phase/Frequency Detector Output. This is a 3-state current-source/sink output for use as a loop error signal when combined with an external low-pass filter. The phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 19.

POL bit (C7) in the C register = low (see Figure 15)

Frequency of  $f_y > f_R$  or Phase of  $f_y$  Leading  $f_R$ : current-sinking pulses from a floating state

Frequency of  $f_y < f_R$  or Phase of  $f_y$  Lagging  $f_R$ : current-sourcing pulses from a floating state

Frequency and Phase of  $f_y = f_R$ : essentially a floating state; voltage at pin determined by loop filter

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ : current-sourcing pulses from a floating state

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ : current-sinking pulses from a floating state

Frequency and Phase of  $f_V = f_R$ : essentially a floating state; voltage at pin determined by loop filter

This output can be enabled, disabled, and inverted via the C register. If desired,  $PD_{Out}$  can be forced to the floating state by utilization of the disable feature in the C register (bit C6). This is a patented feature. Similarly,  $PD_{Out}$  is forced to the floating state when the device is put into standby (STBY bit C4 = high).

The  $PD_{Out}$  circuit is powered by  $V_{PD}$ . The phase detector gain is controllable by bits C3, C2, and C1: gain (in amps per radian) =  $PD_{Out}$  current divided by  $2\pi$ .

#### $\phi_R$ and $\phi_V$ (Pins 3 and 4)

Double-Ended Phase/Frequency Detector Outputs. These outputs can be combined externally to generate a loop error signal. Through use of a Motorola patented technique, the detector's dead zone has been eliminated. Therefore, the phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 19.

POL bit (C7) in the C register = low (see Figure 15)

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_V$  = negative pulses,  $\phi_R$  = essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_V$  = essentially high,  $\phi_R$  = negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_R$  = negative pulses,  $\phi_V$  = essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_R$  = essentially high,  $\phi_V$  = negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

These outputs can be enabled, disabled, and interchanged via C register bits C6 or C4. This is a patented feature. Note that when disabled or in standby,  $\phi_R$  and  $\phi_V$  are forced to their rest condition (high state).

The  $\phi_R$  and  $\phi_V$  output signal swing is approximately from GND to  $V_{PD}$ .

#### LD (Pin 2)

Lock Detector Output. This output is essentially at a high level with narrow low-going pulses when the loop is locked ( $f_R$  and  $f_V$  of the same phase and frequency). The output pulses low when  $f_V$  and  $f_R$  are out of phase or different frequencies. LD is the logical ANDing of  $\phi_R$  and  $\phi_V$ . See Figure 19.

This output can be enabled and disabled via the C register. This is a patented feature. Upon power up, on-chip initialization circuitry disables LD to a static low logic level to prevent a false lock signal. If unused, LD should be disabled and left open.

The LD output signal swing is approximately from GND to  $V_{DD}$ .

#### Rx (Pin 8)

External Resistor. A resistor tied between this pin and GND, in conjunction with bits in the C register, determines the amount of current that the  $PD_{Out}$  pin sinks and sources. When bits C2 and C3 are both set high, the maximum current is obtained at  $PD_{Out}$ ; see Figure 15 for other values of current. To achieve a maximum current of 2 mA, the resistor should be about 22 k $\Omega$  when  $V_{PD}$  is 5 V.

When the  $\phi_R$  and  $\phi_V$  outputs are used, the Rx pin may be floated.

#### TEST POINT PINS

##### Test 1 (Pin 9)

Modulus Control Signal. This pin may be used in conjunction with the Test 2 pin for access to the on-board 64/65 prescaler. When Test 1 is low, the prescaler divides by 65. When high, the prescaler divides by 64.

#### CAUTION

This pin is an unbuffered output and must be floated in an actual application. This pin may be attached to an isolated pad with no trace.

##### Test 2 (Pin 13)

Prescaler Output. This pin may be used to access to the on-board 64/65 prescaler output.

#### CAUTION

This pin is an unbuffered output and must be floated in an actual application. This pin may be attached to an isolated pad with no trace.

#### POWER SUPPLY PINS

##### $V_{DD}$ (Pin 14)

Positive Supply Potential. This pin supplies power to the main CMOS digital portion of the device. The voltage range is + 2.7 to + 5.0 V with respect to the GND pin.

For optimum performance,  $V_{DD}$  should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

##### $V_{CC}$ (Pin 12)

Positive Supply Potential. This pin supplies power to the RF amp and 64/65 prescaler. The voltage range is + 2.7 to + 5.0 V with respect to the GND pin. In the standby mode, the  $V_{CC}$  pin still draws a few milliamps from the power supply. This current drain can be eliminated with the use of transistor Q1 as shown in Figure 23.

For optimum performance,  $V_{CC}$  should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

### V<sub>PD</sub> (Pin 5)

Positive Supply Potential. This pin supplies power to both phase/frequency detectors A and B. The voltage applied on this pin must be  $\geq V_{DD}$  but not more than 5.5 V. The voltage range for  $V_{PD}$  is 4.5 to 5.5 V with respect to the GND pin when using  $PD_{OUT}$  and 2.7 to 5.5 V when using  $\phi_R$ ,  $\phi_V$  outputs.

For optimum performance,  $V_{PD}$  should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

### GND (Pin 7)

Common ground.

**Nominal MC145192  $PD_{out}$  Source Current vs  $R_x$  Resistance**

NOTE: The MC145192 is optimized for  $R_x$  values in the 18 k $\Omega$  to 40 k $\Omega$  range. For example, to achieve 0.3 mA of output current, it is preferable to use a 30-k $\Omega$  resistor for  $R_x$  and bit settings for 25% (as shown in Table 3).

**Figure 14.**

\* At this point, the new byte is transferred to the C register and stored. No other registers are affected.

- C7 – POL: Selects the output polarity of the phase/frequency detectors. When set high, this bit inverts PD<sub>Out</sub> and interchanges the  $\phi_R$  function with  $\phi_Y$  as depicted in Figure 19. Also see the phase detector output pin descriptions for more information. This bit is cleared low at power up.
- C6 – PDA/B: Selects which phase/frequency detector is to be used. When set high, enables the output of phase/frequency detector A (PD<sub>Out</sub>) and disables phase/frequency detector B by forcing  $\phi_R$  and  $\phi_Y$  to the static high state. When cleared low, phase/frequency detector B is enabled ( $\phi_R$  and  $\phi_Y$ ) and phase/frequency detector A is disabled with PD<sub>Out</sub> forced to the high-impedance state. This bit is cleared low at power up.
- C5 – LDE: Enables the lock detector output when set high. When the bit is cleared low, the LD output is forced to a static low level. This bit is cleared low at power up.
- C4 – STBY: When set high, places the CMOS section of device, which is powered by the V<sub>DD</sub> and V<sub>PD</sub> pins, in the standby mode for reduced power consumption: PD<sub>Out</sub> is forced to the high-impedance state,  $\phi_R$  and  $\phi_Y$  are forced high, the A, N, and R counters are inhibited from counting, and the Rx current is shut off. In standby, the state of LD is determined by bit C5. C5 low forces LD low (no change). C5 high forces LD static high. During standby, data is retained in the A, R, and C registers. The condition of REF/OSC circuitry is determined by the control bits in the R register: R13, R14, and R15. However, if REF<sub>Out</sub> = static low is selected, the internal feedback resistor is disconnected and the input is inhibited when in standby; in addition, the REF<sub>In</sub> input only presents a capacitive load. NOTE: Standby does not affect the other modes of the REF/OSC circuitry. When C4 is reset low, the part is taken out of standby in 2 steps. First, the REF<sub>In</sub> (only in one mode) resistor is reconnected, all counters are enabled, and the Rx current is enabled. Any  $f_R$  and  $f_Y$  signals are inhibited from toggling the phase/frequency detectors and lock detector. Second, when the first  $f_Y$  pulse occurs, the R counter is jam loaded, and the phase/frequency and lock detectors are initialized. Immediately after the jam load, the A, N, and R counters begin counting down together. At this point, the  $f_R$  and  $f_Y$  pulses are enabled to the phase and lock detectors. This is a patented feature.
- C3, C2 – I2, I1: Controls the PD<sub>Out</sub> source/sink current per Tables 2 and 3. With both bits high, the maximum current (as set by Rx) is available. Also, see C1 bit description.
- C1 – Port: When the Output A pin is selected as “Port” via bits A22 and A23, C1 determines the state of Output A. When C1 is set high, Output A is forced high; C1 low forces Output A low. When Output A is not selected as “Port,” C1 controls whether the PD<sub>Out</sub> step size is 10% or 25%. (See Tables 2 and 3.) When low, steps are 10%. When high, steps are 25%. Default is 10% steps when Output A is selected as “Port.” The Port bit is not affected by the standby mode.
- C0 – Out B: Determines the state of Output B. When C0 is set high, Output B is high-impedance; C0 low forces Output B low. The Out B bit is not affected by the standby mode. This bit is cleared low at power up.

**Figure 15. C Register Access and Format (8 Clock Cycles Are Used)**

**Table 2. PD<sub>Out</sub> Current, C1 = Low with Output A NOT Selected as “Port”; Also, Default Mode When Output A Selected as “Port”**

C3	C2	PD <sub>Out</sub> Current
0	0	70%
0	1	80%
1	0	90%
1	1	100%

**Table 3. PD<sub>Out</sub> Current, C1 = High with Output A NOT Selected as “Port”**

C3	C2	PD <sub>Out</sub> Current
0	0	25%
0	1	50%
1	0	75%
1	1	100%

- NOTES:
1. Bits R15 through R13 control the configurable "OSC or 4-stage divider" block (see Block Diagram).
  2. Bits R12 through R0 control the "13-stage R counter" block (see Block Diagram).
  3. A power-on initialize circuit forces a default REF<sub>in</sub> to REF<sub>out</sub> ratio of eight.
  4. At this point, bits R13, R14, and R15 are stored and sent to the "OSC or 4-Stage Divider" block in the Block Diagram. Bits R0 – R12 are loaded into the first buffer in the double-buffered section of the R register. Therefore, the R counter divide ratio is not altered yet and retains the previous ratio loaded. The C and A registers are not affected.
  5. At this point, bits R0 through R12 are transferred to the second buffer of the R register. The R counter begins dividing by the new ratio after completing the rest of the present count cycle. Clock must be low during the Enable pulse, as shown. Also, see note 3 of Figure 16 for an alternate method of loading the second buffer in the R register. The C and A registers are not affected. The first buffer of the R register is not affected.
  6. Allows direct access to reference input of phase/frequency detectors.

Figure 17. R Register Access and Format (16 Clock Cycles Are Used)

NOTE: It may not be convenient to control the  $\overline{\text{Enable}}$  or Clock pins high during power up per the Pin Descriptions. If this is the case, the part may be initialized through the serial port as shown in the figure above. The sequence is similar to accessing the registers except that the Clock must remain high at least 100 ns after  $\overline{\text{Enable}}$  is brought high. Note that 3 groups of 5 bits are needed.

**Figure 18. Initializing the PLL through the Serial Port**

$V_H$  = High voltage level

$V_L$  = Low voltage level

\* At this point, when both  $f_R$  and  $f_V$  are in phase, the output source and sink circuits are turned on for a short interval.

NOTE: The  $\text{PD}_{\text{Out}}$  either sources or sinks current during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low pass filter capacitor.  $\text{PD}_{\text{Out}}$ ,  $\phi_R$ , and  $\phi_V$  are shown with the polarity bit (POL) = low; see Figure 15 for POL.

**Figure 19. Phase/Frequency Detectors and Lock Detector Output Waveforms**

## DESIGN CONSIDERATIONS

### CRYSTAL OSCILLATOR CONSIDERATIONS

The following options may be considered to provide a reference frequency to Motorola's CMOS frequency synthesizers.

#### USE OF A HYBRID CRYSTAL OSCILLATOR

Commercially available temperature-compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide very stable reference frequencies. An oscillator capable of CMOS logic levels at the output may be direct or dc coupled to REF<sub>in</sub>. If the oscillator does not have CMOS logic levels on the outputs, capacitive or ac coupling to REF<sub>in</sub> may be used. See Figure 8.

For additional information about TCXOs and data clock oscillators, please consult the latest version of the *eem Electronic Engineers Master Catalog*, the *Gold Book*, or similar publications.

#### DESIGN AN OFF-CHIP REFERENCE

The user may design an off-chip crystal oscillator using discrete transistors or ICs specifically developed for crystal oscillator applications, such as the MC12061 MECL device. The reference signal from the MECL device is ac coupled to REF<sub>in</sub>. (See Figure 8.) For large amplitude signals (standard CMOS logic levels), dc coupling may be used.

#### USE OF THE ON-CHIP OSCILLATOR CIRCUITRY

The on-chip amplifier (a digital inverter) along with an appropriate crystal may be used to provide a reference source frequency. A fundamental mode crystal, parallel resonant at the desired operating frequency, should be connected as shown in Figure 20.

The crystal should be specified for a loading capacitance, C<sub>L</sub>, which does not exceed approximately 20 pF when used at the highest operating frequency of 10 MHz. Assuming R1 = 0 Ω, the shunt load capacitance, C<sub>L</sub>, presented across the crystal can be estimated to be:

$$C_L = \frac{C_{in}C_{out}}{C_{in} + C_{out}} + C_a + C_{stray} + \frac{C1 \cdot C2}{C1 + C2}$$

where

C<sub>in</sub> = 5 pF (see Figure 21)

C<sub>out</sub> = 6 pF (see Figure 21)

C<sub>a</sub> = 1 pF (see Figure 21)

C1 and C2 = external capacitors (see Figure 20)

C<sub>stray</sub> = the total equivalent external circuit stray capacitance appearing across the crystal terminals

The oscillator can be "trimmed" on-frequency by making either a portion or all of C1 variable. The crystal and associated components must be located as close as possible to the REF<sub>in</sub> and REF<sub>out</sub> pins to minimize distortion, stray capacitance, stray inductance, and startup stabilization time. Circuit stray capacitance can also be handled by adding the appropriate stray value to the values for C<sub>in</sub> and C<sub>out</sub>. For this approach, the term C<sub>stray</sub> becomes zero in the above expression for C<sub>L</sub>.

Power is dissipated in the effective series resistance of the crystal, R<sub>e</sub>, in Figure 22. The maximum drive level specified

by the crystal manufacturer represents the maximum stress that the crystal can withstand without damage or excessive shift in operating frequency. R1 in Figure 20 limits the drive level. The use of R1 is not necessary in most cases.

To verify that the maximum dc supply voltage does not cause the crystal to be overdriven; monitor the output frequency (f<sub>R</sub>) at Output A as a function of supply voltage. (REF<sub>out</sub> is not used because loading impacts the oscillator.) The frequency should increase very slightly as the dc supply voltage is increased. An overdriven crystal decreases in frequency or becomes unstable with an increase in supply voltage. The operating supply voltage must be reduced or R1 must be increased in value if the overdriven condition exists. Note that the oscillator start-up time is proportional to the value of R1.

Through the process of supplying crystals for use with CMOS inverters, many crystal manufacturers have developed expertise in CMOS oscillator design with crystals. Discussions with such manufacturers can prove very helpful. See Table 4.

\* May be needed in certain cases. See text.

## PHASE-LOCKED LOOP — LOW-PASS FILTER DESIGN

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC}}$$

$$\zeta = \frac{R}{2} \sqrt{\frac{K_\phi K_{VCO} C}{N}} = \frac{\omega_n RC}{2}$$

$$Z(s) = \frac{1 + sRC}{sC}$$

NOTE:

For (A), using  $K_\phi$  in amps per radian with the filter's impedance transfer function,  $Z(s)$ , maintains units of volts per radian for the detector/filter combination. Additional sideband filtering can be accomplished by adding a capacitor  $C'$  across  $R$ . The corner  $\omega_c = 1/RC'$  should be chosen such that  $\omega_n$  is not significantly affected.

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NCR_1}}$$

$$\zeta = \frac{\omega_n R_2 C}{2}$$

ASSUMING GAIN A IS VERY LARGE, THEN:

$$F(s) = \frac{R_2 s C + 1}{R_1 s C}$$

NOTE:

For (B),  $R_1$  is frequently split into two series resistors; each resistor is equal to  $R_1$  divided by 2. A capacitor  $C_C$  is then placed from the midpoint to ground to further filter the error pulses. The value of  $C_C$  should be such that the corner frequency of this network does not significantly affect  $\omega_n$ .

\* The  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. The  $\phi_R$  and  $\phi_V$  outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp used in the combiner/loop filter.

DEFINITIONS:

$N$  = Total Division Ratio in Feedback Loop

$K_\phi$  (Phase Detector Gain) =  $I_{PDout}/2\pi$  amps per radian for  $PD_{out}$

$K_\phi$  (Phase Detector Gain) =  $V_{PD}/2\pi$  volts per radian for  $\phi_V$  and  $\phi_R$

$K_{VCO}$  (VCO Transfer Function) =  $\frac{2\pi\Delta f_{VCO}}{\Delta V_{VCO}}$  radians per volt

For a nominal design starting point, the user might consider a damping factor  $\zeta \approx 0.7$  and a natural loop frequency  $\omega_n \approx (2\pi f_R/50)$  where  $f_R$  is the frequency at the phase detector input. Larger  $\omega_n$  values result in faster loop lock times and, for similar sideband filtering, higher  $f_R$ -related VCO sidebands.

Either loop filter (A) or (B) is frequently followed by additional sideband filtering to further attenuate  $f_R$ -related VCO sidebands. This additional filtering may be active or passive.

**NOTES:**

1. When used, the  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information.
2. Transistor Q1 is required only if the standby feature is needed. Q1 permits the bipolar section of the device to be shut down via use of the general-purpose digital pin, Output B. If the standby feature is not needed, tie Pin 12 directly to the power supply.
3. For optimum performance, bypass the  $V_{CC}$ ,  $V_{DD}$ , and  $V_{PD}$  pins to GND with low-inductance capacitors.
4. The R counter is programmed for a divide value =  $REF_{in} / f_R$ . Typically,  $f_R$  is the tuning resolution required for the VCO. Also, the VCO frequency divided by  $f_R = N_T = N \times 64 + A$ ; this determines the values (N, A) that must be programmed into the N and A counters, respectively.

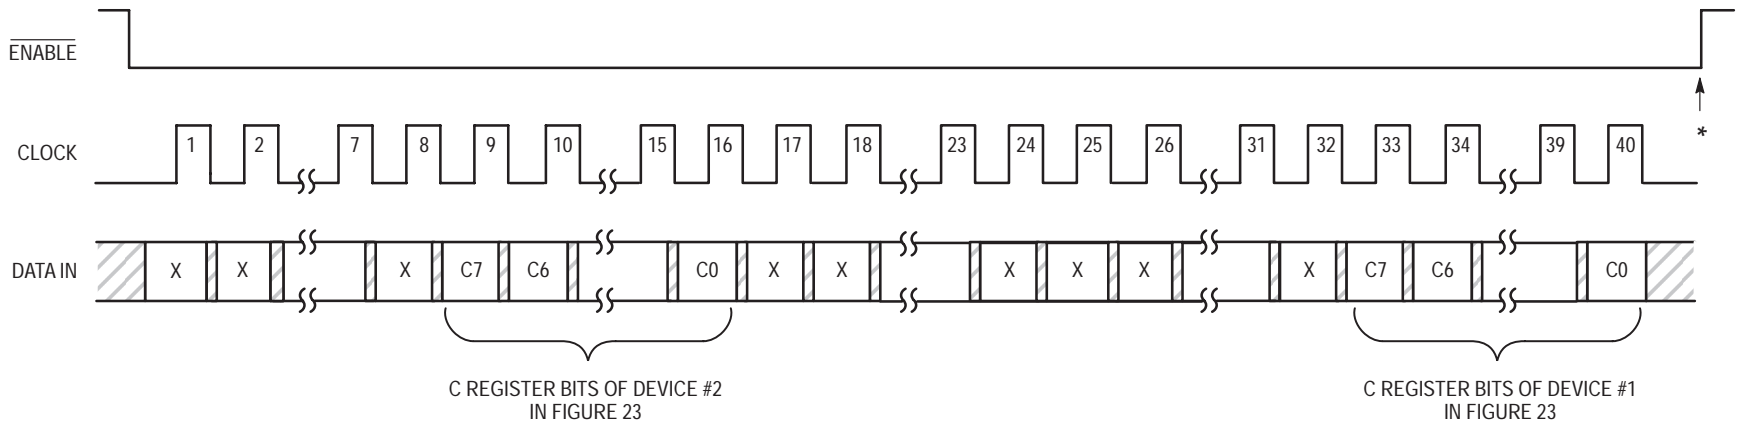

**Figure 23. Example Application**

NOTE: See related Figures 25, 26, and 27.

**Figure 24. Cascading Two Devices**

Figure 25. Accessing the C Registers of Two Cascaded Devices

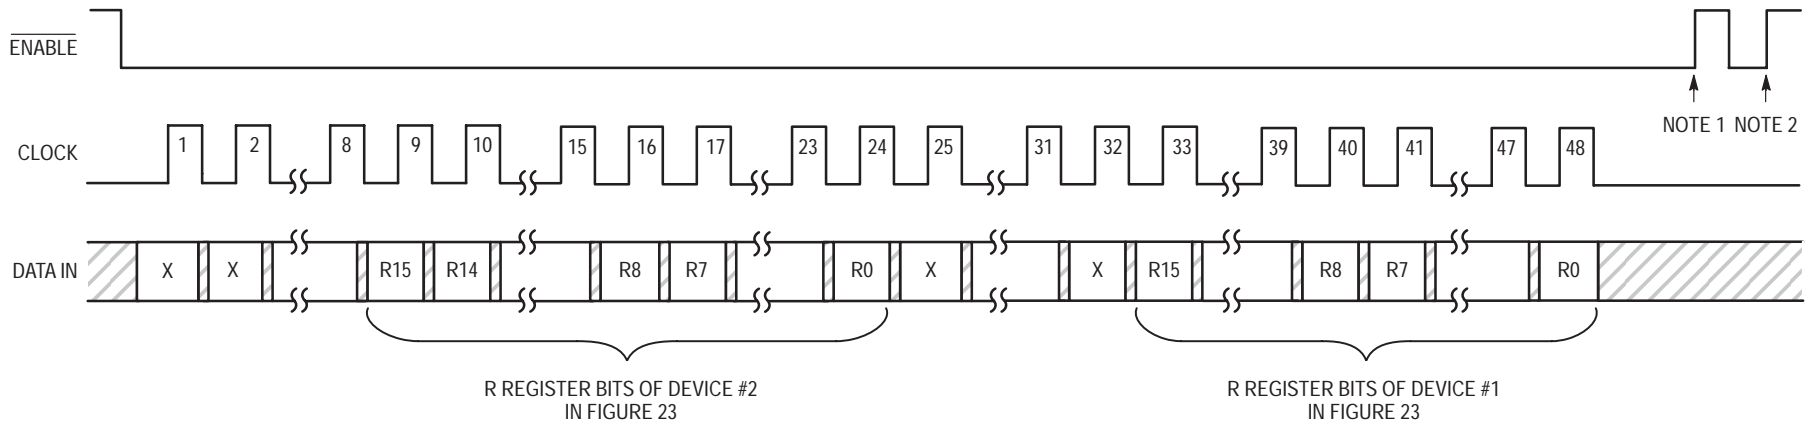

\*At this point, the new bytes are transferred to the C registers of both devices and stored. No other registers are affected.

Figure 26. Accessing the A Registers of Two Cascaded Devices

\*At this point, the new bytes are transferred to the A registers of both devices and stored. Additionally, for both devices, the 13 LSBs in each of the first buffers of the R registers are transferred to the respective R register's second buffer. Thus, the R, N, and A counters can be presented new divide ratios at the same time. The first buffer of each R register is not affected. Neither C register is affected.

Figure 27. Accessing the R Registers of Two Cascaded Devices

NOTES APPLICABLE TO EACH DEVICE:

1. At this point, bits R13, R14, and R15 are stored and sent to the "OSC or 4-Stage Divider" block in the Block Diagram. Bits R0 through R12 are loaded into the first buffer in the double-buffered section of the R register. Therefore, the R counter divide ratio is not altered yet and retains the previous ratio loaded. The C and A registers are not affected.
2. At this point, the bits R0 through R12 are transferred to the second buffer of the R register. The R counter begins dividing by the new ratio after completing the rest of the present count cycle. Clock must be low during the  $\overline{\text{Enable}}$  pulse, as shown. Also, see note of Figure 25 for an alternate method of loading the second buffer in the R register. The C and A registers are not affected. The first buffer of the R register is not affected.

## Product Preview

# 1.1 GHz PLL Frequency Synthesizer

The MC145193 is pin-for-pin compatible with the previous generation MC145190, MC145191 and MC145192 devices. Table 1 highlights the different features in these four devices. The MC145193 is recommended for new designs, and also offers reduced power consumption.

The counters are programmed via a synchronous serial port which is SPI compatible. The serial port is byte-oriented to facilitate control via an MCU. Due to the innovative BitGrabber Plus™ registers, the MC145193 may be cascaded with other peripherals featuring BitGrabber Plus without requiring leading dummy bits or address bits in the serial data stream. In addition, BitGrabber Plus peripherals may be cascaded with existing BitGrabber™ peripherals.

The device features a single-ended current source/sink phase detector A output and a double-ended phase detector B output. Both phase detectors have linear transfer functions (no dead zones). The maximum current of the single-ended phase detector output is determined by an external resistor tied from the Rx pin to ground. This current can be varied via the serial port.

Slew-rate control is provided by a special driver designed for the REF<sub>Out</sub> pin. This minimizes interference caused by REF<sub>Out</sub>.

This part includes a differential RF input that may be operated in a single-ended mode. Also featured are on-board support of an external crystal and a programmable reference output. The R, A, and N counters are fully programmable. The C register (configuration register) allows the part to be configured to meet various applications. A patented feature allows the C register to shut off unused outputs, thereby minimizing system noise and interference.

In order to have consistent lock times and prevent erroneous data from being loaded into the counters, on-board circuitry synchronizes the update of the A register if the A or N counters are loading. Similarly, an update of the R register is synchronized if the R counter is loading.

The double-buffered R register allows new divide ratios to be presented to the three counters (R, A, and N) simultaneously.

- Maximum Operating Frequency: 1100 MHz @ -10 dBm
- Operating Supply Current: 3 mA Nominal at 3.0 V
- Operating Supply Voltage Range (V<sub>DD</sub>, V<sub>CC</sub>, V<sub>PD</sub> Pins): 2.7 to 5.5 V
- Current Source/Sink Phase Detector Output:  
1.7 mA @ 5.0 V or 1.0 mA @ 3.0 V
- Gain of Current Source/Sink Phase/Frequency Detector Controllable via Serial Port
- R Counter Division Range: 1 and 5 to 8191
- Dual-Modulus Capability Provides Total Division up to 262,143
- High-Speed Serial Interface: 4 Mbps
- Output A Pin, When Configured as Data Out, Permits Cascading of Devices
- Two General-Purpose Digital Outputs:  
Output A: Totem-Pole (Push-Pull) with Four Output Modes  
Output B: Open-Drain
- Patented Power-Saving Standby Feature with Orderly Recovery for Minimizing Lock Times, Standby Current: 30 μA
- See App Note AN1253/D for Low-Pass Filter Design, and AN1277/D for Offset Reference PLLs for Fine Resolution or Fast Hopping

## BLOCK DIAGRAM

Supply Connections:  
 Pin 12 =  $V_{CC}$  ( $V+$  To Input AMP and 64/65 Prescaler)  
 Pin 5 =  $V_{PD}$  ( $V+$  To Phase/Frequency Detectors A and B)  
 Pin 14 =  $V_{DD}$  ( $V+$  To Balance Of Circuit)  
 Pin 7 = Gnd (Common Ground)

**Table 1. Differences in the PLL Frequency Synthesizers**

Parameter	Preferred	Not Recommended For New Designs		
	MC145193	MC145192	MC145191	MC145190
Supply Voltage, $V_{DD}$ and $V_{CC}$ (main supply)	2.7 to 5.5 V	2.7 to 5.0 V	4.5 to 5.5 V	4.5 to 5.5 V
Supply Voltage, $V_{PD}$ (charge pump supply)	2.7 to 5.5 V	4.5 to 5.5 V	4.5 to 5.5 V	8.0 to 9.5 V
Supply Current	3 mA	6 mA	7 mA	7 mA
Value of External Resistor Rx, typical	3.9 k $\Omega$ for 1.7 mA [Note]	22 k $\Omega$ for 2.0 mA	18 k $\Omega$ for 2.0 mA	47 k $\Omega$ for 2.0 mA
Serial Programming with only 1 PLL (not cascaded)	Same, No Change	Same	Same	Same
Serial Programming with 2 or more PLLS (cascaded)	No leading dummy bits	Leading dummy bits	Leading dummy bits	Leading dummy bits

NOTE: Preliminary value.

## 2.0 GHz PLL Frequency Synthesizer

### Includes On-Board 64/65 Prescaler

The MC145201 is a single-package synthesizer with serial interface capable of direct usage up to 2.0 GHz. A special architecture makes this PLL very easy to program because a byte-oriented format is utilized. Due to the patented BitGrabber™ registers, no address/steering bits are required for *random access* of the three registers. Thus, tuning can be accomplished via a 3-byte serial transfer to the 24-bit A register. The interface is both SPI and MICROWIRE™ compatible.

The device features a single-ended current source/sink phase detector output and a double-ended phase detector output. Both phase detectors have linear transfer functions (no dead zones). The maximum current of the single-ended phase detector output is determined by an external resistor tied from the Rx pin to ground. This current can be varied via the serial port.

The MC145201 has phase/frequency detectors optimized for single-supply systems of 5 V ±10%.

The part includes a differential RF input which may be operated in a single-ended mode. Also featured are on-board support of an external crystal and a programmable reference output. The R, A, and N counters are fully programmable. The C register (configuration register) allows the parts to be configured to meet various applications. A patented feature allows the C register to shut off unused outputs, thereby minimizing system noise and interference.

In order to have consistent lock times and prevent erroneous data from being loaded into the counters, on-board circuitry synchronizes the update of the A register if the A or N counters are loading. Similarly, an update of the R register is synchronized if the R counter is loading.

The double-buffered R register allows new divide ratios to be presented to the three counters (R, A, and N) simultaneously.

- Maximum Operating Frequency: 2000 MHz @  $V_{in} = 200$  mV p-p
- Operating Supply Current: 12 mA Nominal
- Operating Supply Voltage Range ( $V_{DD}$  and  $V_{CC}$  Pins): 4.5 to 5.5 V
- Operating Supply Voltage Range of Phase Detectors ( $V_{PD}$  Pin): 4.5 to 5.5 V
- Current Source/Sink Phase Detector Output Capability: 2 mA Maximum
- Gain of Current Source/Sink Phase/Frequency Detector Controllable via Serial Port
- Operating Temperature Range: -40 to +85°C
- R Counter Division Range: (1 and) 5 to 8191
- Dual-Modulus Capability Provides Total Division up to 262,143
- High-Speed Serial Interface: 4 Mbps
- OUTPUT A Pin, When Configured as Data Out, Permits Cascading of Devices
- Two General-Purpose Digital Outputs — OUTPUT A: Totem-Pole (Push-Pull)  
OUTPUT B: Open-Drain
- Power-Saving Standby Feature with Orderly Recovery for Minimizing Lock Times, Standby Current: 30  $\mu$ A
- Evaluation Kit Available (Part Number MC145201EVK)
- See Application Note AN1253/D for Low-Pass Filter Design, and AN1277/D for Offset Reference PLLs for Fine Resolution or Fast Hopping

NOT RECOMMENDED FOR NEW DESIGN  
DEVICES TO BE PHASED OUT.  
Consider MC145202-1 for New Designs.

## BLOCK DIAGRAM

### MAXIMUM RATINGS\* (Voltages Referenced to GND, unless otherwise stated)

Symbol	Parameter	Value	Unit
$V_{CC}, V_{DD}$	DC Supply Voltage (Pins 12 and 14)	-0.5 to +6.0	V
$V_{PD}$	DC Supply Voltage (Pin 5)	$V_{DD} - 0.5$ to +6.0	V
$V_{in}$	DC Input Voltage	-0.5 to $V_{DD} + 0.5$	V
$V_{out}$	DC Output Voltage (except OUTPUT B, $PD_{out}$ , $\phi_R$ , $\phi_V$ )	-0.5 to $V_{DD} + 0.5$	V
$V_{out}$	DC Output Voltage (OUTPUT B, $PD_{out}$ , $\phi_R$ , $\phi_V$ )	-0.5 to $V_{PD} + 0.5$	V
$I_{in}, I_{PD}$	DC Input Current, per Pin (Includes $V_{PD}$ )	$\pm 10$	mA
$I_{out}$	DC Output Current, per Pin	$\pm 20$	mA
$I_{DD}$	DC Supply Current, $V_{DD}$ and GND Pins	$\pm 30$	mA
$P_D$	Power Dissipation, per Package	300	mW
$T_{stg}$	Storage Temperature	-65 to +150	$^{\circ}C$
$T_L$	Lead Temperature, 1 mm from Case for 10 seconds	260	$^{\circ}C$

\* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit.

## ELECTRICAL CHARACTERISTICS

( $V_{DD} = V_{CC} = 4.5$  to  $5.5$  V, Voltages Referenced to GND,  $T_A = -40$  to  $+85^\circ\text{C}$ , unless otherwise stated;  
 $V_{PD} = 4.5$  to  $5.5$  V with  $V_{DD} \leq V_{PD}$ .)

Symbol	Parameter	Test Condition	Guaranteed Limit	Unit
$V_{IL}$	Maximum Low-Level Input Voltage ( $D_{in}$ , CLK, $\overline{ENB}$ , $REF_{in}$ )	Device in Reference Mode, DC Coupled	$0.3 \times V_{DD}$	V
$V_{IH}$	Minimum High-Level Input Voltage ( $D_{in}$ , CLK, $\overline{ENB}$ , $REF_{in}$ )	Device in Reference Mode, DC Coupled	$0.7 \times V_{DD}$	V
$V_{hys}$	Minimum Hysteresis Voltage (CLK, $\overline{ENB}$ )		300	mV
$V_{OL}$	Maximum Low-Level Output Voltage ( $REF_{out}$ , OUTPUT A)	$I_{out} = 20 \mu\text{A}$ , Device in Reference Mode	0.1	V
$V_{OH}$	Minimum High-Level Output Voltage ( $REF_{out}$ , OUTPUT A)	$I_{out} = -20 \mu\text{A}$ , Device in Reference Mode	$V_{DD} - 0.1$	V
$I_{OL}$	Minimum Low-Level Output Current ( $REF_{out}$ , LD, $\phi_R$ , $\phi_V$ )	$V_{out} = 0.4$ V	0.36	mA
$I_{OH}$	Minimum High-Level Output Current ( $REF_{out}$ , LD, $\phi_R$ , $\phi_V$ )	$V_{out} = V_{DD} - 0.4$ V for $REF_{out}$ , LD $V_{out} = V_{PD} - 0.4$ V for $\phi_R$ , $\phi_V$	-0.36	mA
$I_{OL}$	Minimum Low-Level Output Current (OUTPUT A, OUTPUT B)	$V_{out} = 0.4$ V	1.0	mA
$I_{OH}$	Minimum High-Level Output Current (OUTPUT A Only)	$V_{out} = V_{DD} - 0.4$ V	-0.6	mA
$I_{in}$	Maximum Input Leakage Current ( $D_{in}$ , CLK, $\overline{ENB}$ , $REF_{in}$ )	$V_{in} = V_{DD}$ or GND, Device in XTAL Mode	$\pm 1.0$	$\mu\text{A}$
$I_{in}$	Maximum Input Current ( $REF_{in}$ )	$V_{in} = V_{DD}$ or GND, Device in Reference Mode	$\pm 150$	$\mu\text{A}$
$I_{OZ}$	Maximum Output Leakage Current ( $PD_{out}$ )	$V_{out} = V_{PD} - 0.5$ or $0.5$ V Output in High-Impedance State	$\pm 200$	nA
$I_{OZ}$	Maximum Output Leakage Current (OUTPUT B)	$V_{out} = V_{PD}$ or GND, Output in High-Impedance State	$\pm 10$	$\mu\text{A}$
$I_{STBY}$	Maximum Standby Supply Current ( $V_{DD} + V_{PD}$ Pins)	$V_{in} = V_{DD}$ or GND; Outputs Open; Device in Standby Mode, Shut-Down Crystal Mode or $REF_{out}$ -Static-Low Reference Mode; OUTPUT B Controlling $V_{CC}$ per Figure 22	30	$\mu\text{A}$
$I_{PD}$	Maximum Phase Detector Quiescent Current ( $V_{PD}$ Pin)	Bit C6 = High Which Selects Phase Detector A, $PD_{out}$ = Open, $PD_{out}$ = Static Low or High, Bit C4 = Low Which is <b>not</b> Standby, $I_{RX} = 113 \mu\text{A}$	600	$\mu\text{A}$
		Bit C6 = Low Which Selects Phase Detector B, $\phi_R$ and $\phi_V$ = Open, $\phi_R$ and $\phi_V$ = Static Low or High, Bit C4 = Low Which is <b>not</b> Standby	30	
$I_T$	Total Operating Supply Current ( $V_{DD} + V_{PD} + V_{CC}$ Pins)	$f_{in} = 2.0$ GHz; $REF_{in} = 13$ MHz @ 1 V p-p; OUTPUT A = Inactive and No Connect; $REF_{out}$ , $\phi_V$ , $\phi_R$ , $PD_{out}$ , LD = No Connect; $D_{in}$ , $\overline{ENB}$ , CLK = $V_{DD}$ or GND, Phase Detector B Enabled (Bit C6 = Low)	*	mA

\* The nominal value = 12 mA. This is not a guaranteed limit.

**ANALOG CHARACTERISTICS—CURRENT SOURCE/SINK OUTPUT—PD<sub>out</sub>**(I<sub>out</sub> ≤ 2 mA, V<sub>DD</sub> = V<sub>CC</sub> = 4.5 to 5.5 V, V<sub>DD</sub> ≤ V<sub>PD</sub>. Voltages Referenced to GND)

Parameter	Test Condition	V <sub>PD</sub>	Guaranteed Limit	Unit
Maximum Source Current Variation	V <sub>out</sub> = 0.5 × V <sub>PD</sub>	4.5	± 20	%
		5.5	± 20	
Maximum Sink-vs-Source Mismatch (Note 3)	V <sub>out</sub> = 0.5 × V <sub>PD</sub>	4.5	12	%
		5.5	12	
Output Voltage Range (Note 3)	I <sub>out</sub> variation ≤ 20%	4.5	0.5 to 4.0	V
		5.5	0.5 to 5.0	

**NOTES:**

1. Percentages calculated using the following formula: (Maximum Value – Minimum Value) / Maximum Value.
2. See Rx Pin Description for external resistor values.
3. This parameter is guaranteed for a given temperature within –40 to +85°C.

**AC INTERFACE CHARACTERISTICS** (V<sub>DD</sub> = 4.5 to 5.5 V, T<sub>A</sub> = –40 to +85°C, C<sub>L</sub> = 50 pF, Input t<sub>r</sub> = t<sub>f</sub> = 10 ns;V<sub>PD</sub> = 4.5 to 5.5 V with V<sub>DD</sub> ≤ V<sub>PD</sub>)

Symbol	Parameter	Figure No.	Guaranteed Limit	Unit
f <sub>clk</sub>	Serial Data Clock Frequency (Note: Refer to Clock t <sub>w</sub> below)	1	dc to 4.0	MHz

## PIN DESCRIPTIONS

### DIGITAL INTERFACE PINS

#### D<sub>in</sub>

##### Serial Data Input (Pin 19)

The bit stream begins with the most significant bit (MSB) and is shifted in on the low-to-high transition of CLK. The bit pattern is 1 byte (8 bits) long to access the C or configuration register, 2 bytes (16 bits) to access the first buffer of the R register, or 3 bytes (24 bits) to access the A register (see Table 1). The values in the C, R, and A registers do not change during shifting because the transfer of data to the registers is controlled by  $\overline{\text{ENB}}$ .

#### CAUTION

The value programmed for the N-counter must be greater than or equal to the value of the A-counter.

The 13 least significant bits (LSBs) of the R register are double-buffered. As indicated above, data is latched into the first buffer on a 16-bit transfer. (The 3 MSBs are not double-buffered and have an immediate effect after a 16-bit transfer.) The second buffer of the R register contains the 13 bits for the R counter. This second buffer is loaded with the contents of the first buffer when the A register is loaded (a 24-bit transfer). This allows presenting new values to the R, A, and N counters simultaneously. If this is not required, then the 16-bit transfer may be followed by pulsing  $\overline{\text{ENB}}$  low with no signal on the CLK pin. This is an alternate method of transferring data to the second buffer of the R register (see Figure 17).

The bit stream needs neither address nor steering bits due to the innovative BitGrabber registers. Therefore, all bits in the stream are available to be data for the three registers. Random access of any register is provided. That is, the registers may be accessed in any sequence. Data is retained in the registers over a supply range of 4.5 to 5.5 V. The formats are shown in Figures 15, 16, and 17.

D<sub>in</sub> typically switches near 50% of V<sub>DD</sub> to maximize noise immunity. This input can be directly interfaced to CMOS devices with outputs guaranteed to switch near rail-to-rail. When interfacing to NMOS or TTL devices, either a level shifter (MC74HC14A, MC14504B) or pull-up resistor of 1 k $\Omega$  to 10 k $\Omega$  must be used. Parameters to consider when sizing the resistor are worst-case I<sub>OL</sub> of the driving device, maximum tolerable power consumption, and maximum data rate.

**Table 1. Register Access**

(MSBs are shifted in first; C0, R0, and A0 are the LSBs)

Number of Clocks	Accessed Register	Bit Nomenclature
8	C Register	C7, C6, C5, . . . , C0
16	R Register	R15, R14, R13, . . . , R0
24	A Register	A23, A22, A21, . . . , A0
Other Values $\leq$ 32	See Figure 13	
Values $>$ 32	See Figures 22–25	

#### CLK

##### Serial Data Clock Input (Pin 18)

Low-to-high transitions on CLK shift bits available at the D<sub>in</sub> pin, while high-to-low transitions shift bits from OUTPUT A (when configured as Data Out, see Pin 16). The 24-1/2-stage shift register is static, allowing clock rates down to dc in a continuous or intermittent mode.

Eight clock cycles are required to access the C register. Sixteen clock cycles are needed for the first buffer of the R register. Twenty-four cycles are used to access the A register. See Table 1 and Figures 15, 16, and 17. The number of clocks required for cascaded devices is shown in Figures 24 through 26.

CLK typically switches near 50% of V<sub>DD</sub> and has a Schmitt-triggered input buffer. Slow CLK rise and fall times are allowed. See the last paragraph of D<sub>in</sub> for more information.

#### NOTE

To guarantee proper operation of the power-on reset (POR) circuit, the CLK pin must be held at GND (with  $\overline{\text{ENB}}$  being a don't care) or  $\overline{\text{ENB}}$  must be held at the potential of the V+ pin (with CLK being a don't care) during power-up. As an alternative, the bit sequence of Figure 13 may be used.

#### $\overline{\text{ENB}}$

##### Active Low Enable Input (Pin 17)

This pin is used to activate the serial interface to allow the transfer of data to/from the device. When  $\overline{\text{ENB}}$  is in an inactive high state, shifting is inhibited and the port is held in the initialized state. To transfer data to the device,  $\overline{\text{ENB}}$  (which must start inactive high) is taken low, a serial transfer is made via D<sub>in</sub> and CLK, and  $\overline{\text{ENB}}$  is taken back high. The low-to-high transition on  $\overline{\text{ENB}}$  transfers data to the C or A registers and first buffer of the R register, depending on the data stream length per Table 1.

#### NOTE

Transitions on  $\overline{\text{ENB}}$  must not be attempted while CLK is high. This puts the device out of synchronization with the microcontroller. Resynchronization occurs when  $\overline{\text{ENB}}$  is high and CLK is low.

This input is also Schmitt-triggered and switches near 50% of V<sub>DD</sub>, thereby minimizing the chance of loading erroneous data into the registers. See the last paragraph of D<sub>in</sub> for more information.

For POR information, see the note for the CLK pin.

#### OUTPUT A

##### Configurable Digital Output (Pin 16)

OUTPUT A is selectable as f<sub>R</sub>, f<sub>V</sub>, Data Out, or Port. Bits A22 and A23 in the A register control the selection; see Figure 16.

If A23 = A22 = high, OUTPUT A is configured as f<sub>R</sub>. This signal is the buffered output of the 13-stage R counter. The f<sub>R</sub> signal appears as normally low and pulses high, and can be used to verify the divide ratio of the R counter. This ratio extends from 5 to 8191 and is determined by the binary value loaded into bits R0 through R12 in the R register. Also, direct access to the phase detectors via the REF<sub>in</sub> pin is allowed by choosing a divide value of 1 (see Figure 17). The maximum frequency at which the phase detectors operate is 2 MHz. Therefore, the frequency of f<sub>R</sub> should not exceed 2 MHz.

If A23 = high and A22 = low, OUTPUT A is configured as  $f_V$ . This signal is the buffered output of the 12-stage N counter. The  $f_V$  signal appears as normally low and pulses high, and can be used to verify the operation of the prescaler, A counter, and N counter. The divide ratio between the  $f_{IN}$  input and the  $f_V$  signal is  $N \times 64 + A$ . N is the divide ratio of the N counter and A is the divide ratio of the A counter. These ratios are determined by bits loaded into the A register. See Figure 16. The maximum frequency at which the phase detectors operate is 2 MHz. Therefore, the frequency of  $f_V$  should not exceed 2 MHz.

If A23 = low and A22 = high, OUTPUT A is configured as Data Out. This signal is the serial output of the 24-1/2-stage shift register. The bit stream is shifted out on the high-to-low transition of the CLK input. Upon power up, OUTPUT A is automatically configured as Data Out to facilitate cascading devices.

If A23 = A22 = low, OUTPUT A is configured as Port. This signal is a general-purpose digital output which may be used as an MCU port expander. This signal is low when the Port bit (C1) of the C register is low, and high when the Port bit is high.

## OUTPUT B

### Open-Drain Digital Output (Pin 15)

This signal is a general-purpose digital output which may be used as an MCU port expander. This signal is low when the Out B bit (C0) of the C register is low. When the Out B bit is high, OUTPUT B assumes the high-impedance state. OUTPUT B may be pulled up through an external resistor or active circuitry to any voltage less than or equal to the potential of the  $V_{PD}$  pin. **Note:** the maximum voltage allowed on the  $V_{PD}$  pin is 5.5 V for the MC145201.

Upon power-up, power-on reset circuitry forces OUTPUT B to a low level.

## REFERENCE PINS

### REF<sub>IN</sub> and REF<sub>OUT</sub>

#### Reference Input and Reference Output (Pins 20 and 1)

Configurable pins for a Crystal or an External Reference. This pair of pins can be configured in one of two modes: the crystal mode or the reference mode. Bits R13, R14, and R15 in the R register control the modes as shown in Figure 17.

In crystal mode, these pins form a reference oscillator when connected to terminals of an external parallel-resonant crystal. Frequency-setting capacitors of appropriate values as recommended by the crystal supplier are connected from each of the two pins to ground (up to a maximum of 30 pF each, including stray capacitance). An external resistor of 1 M $\Omega$  to 15 M $\Omega$  is connected directly across the pins to ensure linear operation of the amplifier. The device is designed to operate with crystals up to 15 MHz; the required connections are shown in Figure 8. To turn on the oscillator, bits R15, R14, and R13 must have an octal value of one (001 in binary, respectively). This is the active-crystal mode shown in Figure 17. In this mode, the crystal oscillator runs and the R Counter divides the crystal frequency, unless the part is in standby. If the part is placed in standby via the C register, the oscillator runs, but the R counter is stopped. However, if bits R15 to R13 have a value of 0, the oscillator is stopped, which saves additional power. This is the shut-down crystal mode (shown in Figure 17) and can be engaged whether in standby or not.

In the reference mode, REF<sub>IN</sub> (Pin 20) accepts a signal up to 27 MHz from an external reference oscillator, such as a TCXO. A signal swinging from at least the  $V_{IL}$  to  $V_{IH}$  levels listed in the Electrical Characteristics table may be directly coupled to the pin. If the signal is less than this level, ac coupling must be used as shown in Figure 8. Due to an on-board resistor which is engaged in the reference modes, an external biasing resistor tied between REF<sub>IN</sub> and REF<sub>OUT</sub> is not required.

With the reference mode, the REF<sub>OUT</sub> pin is configured as the output of a divider. As an example, if bits R15, R14, and R13 have an octal value of seven, the frequency at REF<sub>OUT</sub> is the REF<sub>IN</sub> frequency divided by 16. In addition, Figure 17 shows how to obtain ratios of eight, four, and two. A ratio of one-to-one can be obtained with an octal value of three. Upon power up, a ratio of eight is automatically initialized. The maximum frequency capability of the REF<sub>OUT</sub> pin is 10 MHz. Therefore, for REF<sub>IN</sub> frequencies above 10 MHz, the one-to-one ratio may not be used. Likewise, for REF<sub>IN</sub> frequencies above 20 MHz, the ratio must be more than two.

If REF<sub>OUT</sub> is unused, an octal value of two should be used for R15, R14, and R13 and the REF<sub>OUT</sub> pin should be floated. A value of two allows REF<sub>IN</sub> to be functional while disabling REF<sub>OUT</sub>, which minimizes dynamic power consumption and electromagnetic interference (EMI).

## LOOP PINS

### $f_{IN}$ and $\overline{f_{IN}}$

#### Frequency Inputs (Pins 11 and 10)

These pins are frequency inputs from the VCO. These pins feed the on-board RF amplifier which drives the 64/65 prescaler. These inputs may be fed differentially. However, they usually are used in a single-ended configuration (shown in Figure 7). Note that  $f_{IN}$  is driven while  $\overline{f_{IN}}$  must be tied to ground via a capacitor.

Motorola does not recommend driving  $\overline{f_{IN}}$  while terminating  $f_{IN}$  because this configuration is not tested for sensitivity. The sensitivity is dependent on the frequency as shown in the Loop Specifications table.

### PD<sub>OUT</sub>

#### Single-Ended Phase/Freq. Detector Output (Pin 6)

This is a three-state current-source/sink output for use as a loop error signal when combined with an external low-pass filter. The phase/frequency detector is characterized by a linear transfer function (no dead zone). The operation of the phase/frequency detector is described below and is shown in Figure 18.

POL bit (C7) in the C register = low (see Figure 15)

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ : current-sinking pulses from a floating state

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ : current-sourcing pulses from a floating state

Frequency and Phase of  $f_V = f_R$ : essentially a floating state; voltage at pin determined by loop filter

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ : current-sourcing pulses from a floating state

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ : current-sinking pulses from a floating state

Frequency and Phase of  $f_V = f_R$ : essentially a floating state; voltage at pin determined by loop filter

This output can be enabled, disabled, and inverted via the C register. If desired,  $PD_{OUT}$  can be forced to a floating state by utilization of the disable feature in the C register (bit C6). This is a patented feature. Similarly,  $PD_{OUT}$  is forced to the floating state when the device is put into standby (STBY bit C4 = high).

The  $PD_{OUT}$  circuit is powered by  $V_{PD}$ . The phase detector gain is controllable by bits C3, C2, and C1: gain (in amps per radian) =  $PD_{OUT}$  current divided by  $2\pi$ .

### $\phi_R$ and $\phi_V$ (Pins 3 and 4)

#### Double-Ended Phase/Frequency Detector Outputs

These outputs can be combined externally to generate a loop error signal. Through use of a Motorola patented technique, the detector's dead zone has been eliminated. Therefore, the phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 18.

POL bit (C7) in the C register = low (see Figure 15)

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_V =$  negative pulses,  $\phi_R =$  essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_V =$  essentially high,  $\phi_R =$  negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_R =$  negative pulses,  $\phi_V =$  essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_R =$  essentially high,  $\phi_V =$  negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

These outputs can be enabled, disabled, and interchanged via C register bits C6 or C4. This is a patented feature. Note that when disabled or in standby,  $\phi_R$  and  $\phi_V$  are forced to their rest condition (high state).

The  $\phi_R$  and  $\phi_V$  output signal swing is approximately from GND to  $V_{PD}$ .

### LD

#### Lock Detector Output (Pin 2)

This output is essentially at a high level with narrow low-going pulses when the loop is locked ( $f_R$  and  $f_V$  of the same phase and frequency). The output pulses low when  $f_V$  and  $f_R$  are out of phase or different frequencies. LD is the logical ANDING of  $\phi_R$  and  $\phi_V$  (see Figure 18).

This output can be enabled and disabled via the C register. This is a patented feature. Upon power up, on-chip initialization circuitry disables LD to a static low logic level to prevent a false "lock" signal. If unused, LD should be disabled and left open.

The LD output signal swing is approximately from GND to  $V_{DD}$ .

### Rx

#### External Resistor (Pin 8)

A resistor tied between this pin and GND, in conjunction with bits in the C register, determines the amount of current that the  $PD_{OUT}$  pin sinks and sources. When bits C2 and C3 are both set high, the maximum current is obtained at  $PD_{OUT}$ ; see Tables 2 and 3 for other values of current. To achieve a maximum current of 2 mA, the resistor should be about 18 k $\Omega$  when  $V_{PD}$  is 5.0 V. See Figure 14 if lower maximum current values are desired.

When the  $\phi_R$  and  $\phi_V$  outputs are used, the Rx pin may be floated.

### TEST POINT PINS

#### TEST 1

##### Modulus Control Signal (Pin 9)

This pin may be used in conjunction with the Test 2 pin for access to the on-board 64/65 prescaler. When Test 1 is low, the prescaler divides by 65. When high, the prescaler divides by 64.

#### CAUTION

This pin is an unbuffered output and **must** be floated in an actual application. This pin must be attached to an isolated pad with no trace.

#### TEST 2

##### Prescaler Output (Pin 13)

This pin may be used to access to the on-board 64/65 prescaler output.

#### CAUTION

This pin is an unbuffered output and **must** be floated in an actual application. This pin must be attached to an isolated pad with no trace.

### POWER SUPPLY PINS

#### VDD

##### Positive Power Supply (Pin 14)

This pin supplies power to the main CMOS digital portion of the device. The voltage range is +4.5 to +5.5 V with respect to the GND pin.

For optimum performance,  $V_{DD}$  should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

#### VCC

##### Positive Power Supply (Pin 12)

This pin supplies power to the RF amp and 64/65 prescaler. The voltage range is +4.5 to +5.5 V with respect to the GND pin. In the standby mode, the  $V_{CC}$  pin still draws a few milliamps from the power supply. This current drain can be eliminated with the use of transistor Q1 as shown in Figure 22.

For optimum performance,  $V_{CC}$  should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

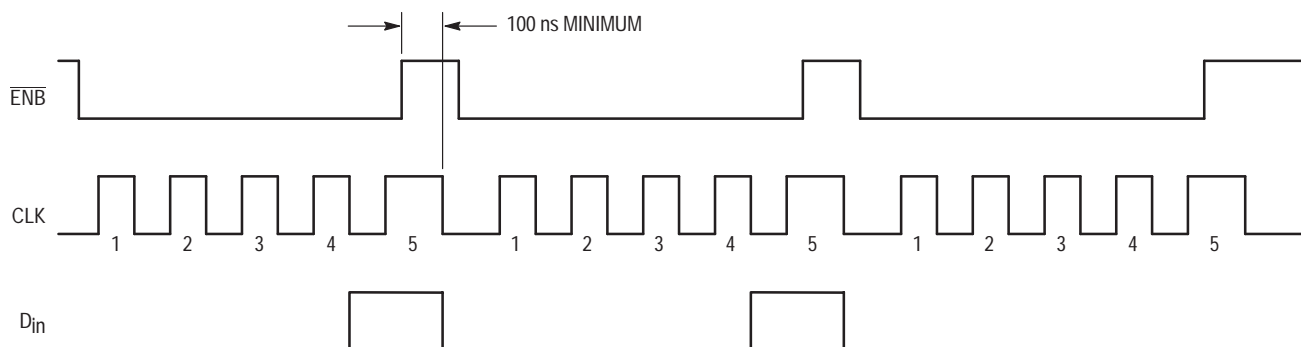

**VPD**  
**Positive Power Supply (Pin 5)**

This pin supplies power to both phase/frequency detectors A and B. The voltage applied on this pin must be no less than the potential applied to the V<sub>DD</sub> pin. The maximum voltage can be +5.5 V with respect to the GND pin.

For optimum performance, V<sub>PD</sub> should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

**GND**  
**Ground (Pin 7)**

Common ground.

NOTE: It may not be convenient to control the ENB or CLK pins during power up per the Pin Descriptions. If this is the case, the part may be initialized through the serial port as shown in the figure above. The sequence is similar to accessing the registers except that the CLK must remain high at least 100 ns after ENB is brought high. Note that 3 groups of 5 bits are needed.

**Figure 13. Initializing the PLL through the Serial Port**

**MC145201**  
**Nominal PD<sub>out</sub> Spurious Current vs f<sub>R</sub> Frequency**  
**(1 V < PD<sub>out</sub> < V<sub>PD</sub> - 1V)**

f <sub>R</sub> (kHz)	Current (RMS nA)
10	3.6
20	4.6
50	17
100	75
200	244

NOTE: For information on spurious current measurement see AN1253/D, "An Improved PLL Design Method Without ω<sub>n</sub> and ζ".

**Table 2. PD<sub>out</sub> Current, C1 = Low with OUTPUT A NOT Selected as "Port"; Also, Default Mode When OUTPUT A Selected as "Port"**

C3	C2	PD <sub>out</sub> Current
0	0	70%
0	1	80%
1	0	90%
1	1	100%

**Table 3. PD<sub>out</sub> Current, C1 = High with OUTPUT A NOT Selected as "Port"**

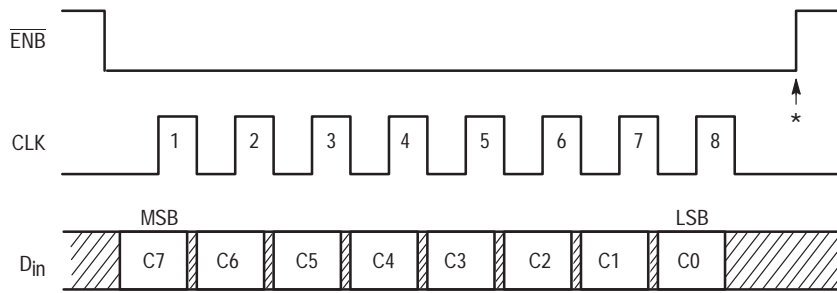

C3	C2	PD <sub>out</sub> Current
0	0	25%
0	1	50%
1	0	75%
1	1	100%

**Nominal MC145201 PD<sub>out</sub> Source Current vs Rx Resistance**

NOTE: The MC145201 is optimized for R<sub>x</sub> values in the 18 kΩ to 40 kΩ range. For example, to achieve 0.3 mA of output current, it is preferable to use a 30-kΩ resistor for R<sub>x</sub> and bit settings for 25% (as shown in Table 3).

**Figure 14.**

\* At this point, the new byte is transferred to the C register and stored. No other registers are affected.

- C7 — POL: Selects the output polarity of the phase/frequency detectors. When set high, this bit inverts the polarity of  $PD_{out}$  and interchanges the  $\phi_R$  function with  $\phi_V$  as depicted in Figure 18. Also see the phase detector output pin descriptions for more information. This bit is cleared low at power up.
- C6 — PDA/B: Selects which phase/frequency detector is to be used. When set high, enables the output of phase/frequency detector A ( $PD_{out}$ ) and disables phase/frequency detector B by forcing  $\phi_R$  and  $\phi_V$  to the static high state. When cleared low, phase/frequency detector B is enabled ( $\phi_R$  and  $\phi_V$ ) and phase/frequency detector A is disabled with  $PD_{out}$  forced to the high-impedance state. This bit is cleared low at power up.
- C5 — LDE: Enables the lock detector output (LD) when set high. When the bit is cleared low, the LD output is forced to a static low level. This bit is cleared low at power up.
- C4 — STBY: When set high, places the CMOS section of device, which is powered by the  $V_{DD}$  and  $V_{PD}$  pins, in the standby mode for reduced power consumption:  $PD_{out}$  is forced to the high-impedance state,  $\phi_R$  and  $\phi_V$  are forced high, the A, N, and R counters are inhibited from counting, and the Rx current is shut off. In standby, the state of LD is determined by bit C5. C5 low forces LD low (no change). C5 high forces LD static high. During standby, data is retained in the A, R, and C registers. The condition of REF/OSC circuitry is determined by the control bits in the R register: R13, R14, and R15. However, if  $REF_{out}$  = static low is selected, the internal feedback resistor is disconnected and the input is inhibited when in standby; in addition, the  $REF_{in}$  input only presents a capacitive load. NOTE: Standby does not affect the other modes of the REF/OSC circuitry.
- When C4 is reset low, the part is taken out of standby in 2 steps. First, the  $REF_{in}$  (only in one mode) resistor is reconnected, all counters are enabled, and the Rx current is enabled. Any  $f_R$  and  $f_V$  signals are inhibited from toggling the phase/frequency detectors and lock detector. Second, when the first  $f_V$  pulse occurs, the R counter is jam loaded, and the phase/frequency and lock detectors are initialized. Immediately after the jam load, the A, N, and R counters begin counting down together. At this point, the  $f_R$  and  $f_V$  pulses are enabled to the phase and lock detectors. (Patented feature.)
- C3, C2 — I2, I1: Controls the  $PD_{out}$  source/sink current per Tables 2 and 3. With both bits high, the maximum current (as set by Rx per Figure 14) is available. Also, see C1 bit description.
- C1 — Port: When the OUTPUT A pin is selected as "Port" via bits A22 and A23, C1 determines the state of OUTPUT A. When C1 is set high, OUTPUT A is forced high; C1 low forces OUTPUT A low. When OUTPUT A is NOT selected as "Port," C1 controls whether the  $PD_{out}$  step size is 10% or 25%. (See Tables 2 and 3.) When low, steps are 10%. When high, steps are 25%. Default is 10% steps when OUTPUT A is selected as "Port." The Port bit is not affected by the standby mode.
- C0 — Out B: Determines the state of OUTPUT B. When C0 is set high, OUTPUT B is high-impedance; C0 low forces OUTPUT B low. The Out B bit is not affected by the standby mode. This bit is cleared low at power up.

**Figure 15. C Register Access and Format (8 Clock Cycles are Used)**

- NOTES:
1. Bits R15 through R13 control the configurable “OSC or 4–stage divider” block (see Block Diagram).
  2. Bits R12 through R0 control the “13–stage R counter” block (see Block Diagram).
  3. A power–on initialize circuit forces a default REF<sub>in</sub> to REF<sub>out</sub> ratio of eight.
  4. At this point, bits R13, R14, and R15 are stored and sent to the “OSC or 4–Stage Divider” block in the Block Diagram. Bits R0 through R12 are loaded into the first buffer in the double–buffered section of the R register. Therefore, the R counter divide ratio is not altered yet and retains the previous ratio loaded. The C and A registers are not affected.
  5. At this point, bits R0 through R12 are transferred to the second buffer of the R register. The R counter begins dividing by the new ratio after completing the rest of the present count cycle. CLK must be low during the ENB pulse, as shown. Also, see note 3 of Figure 16 for an alternate method of loading the second buffer in the R register. The C and A registers are not affected. The first buffer of the R register is not affected.
  6. Allows direct access to reference input of phase/frequency detectors.

**Figure 17. R Register Access and Format (16 Clock Cycles Are Used)**

$V_H$  = High voltage level

$V_L$  = Low voltage level

\*At this point, when both  $f_R$  and  $f_V$  are in phase, the output source and sink circuits are turned on for a short interval.

NOTE: The  $PD_{out}$  either sources or sinks current during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low-pass filter capacitor.  $PD_{out}$ ,  $\phi_R$ , and  $\phi_V$  are shown with the polarity bit (POL) = low; see Figure 14 for POL.

Figure 18. Phase/Frequency Detectors and Lock Detector Output Waveforms

## DESIGN CONSIDERATIONS

### CRYSTAL OSCILLATOR CONSIDERATIONS

The following options may be considered to provide a reference frequency to Motorola's CMOS frequency synthesizers.

#### Use of a Hybrid Crystal Oscillator

Commercially available temperature-compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide very stable reference frequencies. An oscillator capable of CMOS logic levels at the output may be direct or dc coupled to  $REF_{in}$ . If the oscillator does not have CMOS logic levels on the outputs, capacitive or ac coupling to  $REF_{in}$  may be used (see Figure 8).

For additional information about TCXOs and data clock oscillators, please consult the latest version of the *eem Electronic Engineers Master Catalog*, the *Gold Book*, or similar publications.

#### Design an Off-Chip Reference

The user may design an off-chip crystal oscillator using discrete transistors or ICs specifically developed for crystal oscillator applications, such as the MC12061 MECL device. The reference signal from the MECL device is ac coupled to  $REF_{in}$  (see Figure 8). For large amplitude signals (standard CMOS logic levels), dc coupling may be used.

#### Use of the On-Chip Oscillator Circuitry

The on-chip amplifier (a digital inverter) along with an appropriate crystal may be used to provide a reference source

frequency. A fundamental mode crystal, parallel resonant at the desired operating frequency, should be connected as shown in Figure 19.

The crystal should be specified for a loading capacitance ( $C_L$ ) which does not exceed approximately 20 pF when used at the highest operating frequency of 15 MHz. Assuming  $R1 = 0 \Omega$ , the shunt load capacitance ( $C_L$ ) presented across the crystal can be estimated to be:

$$C_L = \frac{C_{in}C_{out}}{C_{in}+C_{out}} + C_a + C_{stray} + \frac{C1 \cdot C2}{C1 + C2}$$

where

$C_{in} = 5 \text{ pF}$  (see Figure 20)

$C_{out} = 6 \text{ pF}$  (see Figure 20)

$C_a = 1 \text{ pF}$  (see Figure 20)

$C1$  and  $C2$  = external capacitors (see Figure 19)

$C_{stray}$  = the total equivalent external circuit stray capacitance appearing across the crystal terminals

The oscillator can be "trimmed" on-frequency by making a portion or all of  $C1$  variable. The crystal and associated components must be located as close as possible to the  $REF_{in}$  and  $REF_{out}$  pins to minimize distortion, stray capacitance, stray inductance, and startup stabilization time. Circuit stray capacitance can also be handled by adding the appropriate stray value to the values for  $C_{in}$  and  $C_{out}$ . For this approach, the term  $C_{stray}$  becomes 0 in the above expression for  $C_L$ .

Power is dissipated in the effective series resistance of the crystal,  $R_e$ , in Figure 21. The maximum drive level specified by the crystal manufacturer represents the maximum stress that the crystal can withstand without damage or excessive shift in operating frequency.  $R_1$  in Figure 19 limits the drive level. The use of  $R_1$  is not necessary in most cases.

To verify that the maximum dc supply voltage does not cause the crystal to be overdriven, monitor the output frequency ( $f_R$ ) at OUTPUT A as a function of supply voltage. ( $REF_{out}$  is not used because loading impacts the oscillator.) The frequency should increase very slightly as the dc supply voltage is increased. An overdriven crystal decreases in frequency or becomes unstable with an increase in supply voltage. The operating supply voltage must be reduced or  $R_1$  must be increased in value if the overdriven condition exists. The user should note that the oscillator start-up time is proportional to the value of  $R_1$ .

Through the process of supplying crystals for use with CMOS inverters, many crystal manufacturers have developed expertise in CMOS oscillator design with crystals. Discussions with such manufacturers can prove very helpful (see Table 4).

## PHASE-LOCKED LOOP — LOW-PASS FILTER DESIGN

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC}}$$

$$\zeta = \frac{R}{2} \sqrt{\frac{K_\phi K_{VCO} C}{N}} = \frac{\omega_n RC}{2}$$

$$Z(s) = \frac{1 + sRC}{sC}$$

**NOTE:**

For (A), using  $K_\phi$  in amps per radian with the filter's impedance transfer function,  $Z(s)$ , maintains units of volts per radian for the detector/filter combination. Additional sideband filtering can be accomplished by adding a capacitor  $C'$  across  $R$ . The corner  $\omega_c = 1/RC'$  should be chosen such that  $\omega_n$  is not significantly affected.

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NCR_1}}$$

$$\zeta = \frac{\omega_n R_2 C}{2}$$

ASSUMING GAIN A IS VERY LARGE, THEN:

$$F(s) = \frac{R_2 s C + 1}{R_1 s C}$$

**NOTE:**

For (B),  $R_1$  is frequently split into two series resistors; each resistor is equal to  $R_1$  divided by 2. A capacitor  $C_C$  is then placed from the midpoint to ground to further filter the error pulses. The value of  $C_C$  should be such that the corner frequency of this network does not significantly affect  $\omega_n$ .

\* The  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. The  $\phi_R$  and  $\phi_V$  outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp used in the combiner/loop filter.

**DEFINITIONS:**

$N$  = Total Division Ratio in Feedback Loop  
 $K_\phi$  (Phase Detector Gain) =  $I_{PD_{out}}/2\pi$  amps per radian for  $PD_{out}$   
 $K_\phi$  (Phase Detector Gain) =  $V_{PD}/2\pi$  volts per radian for  $\phi_V$  and  $\phi_R$

$$K_{VCO} \text{ (VCO Transfer Function)} = \frac{2\pi\Delta f_{VCO}}{\Delta V_{VCO}} \text{ radians per volt}$$

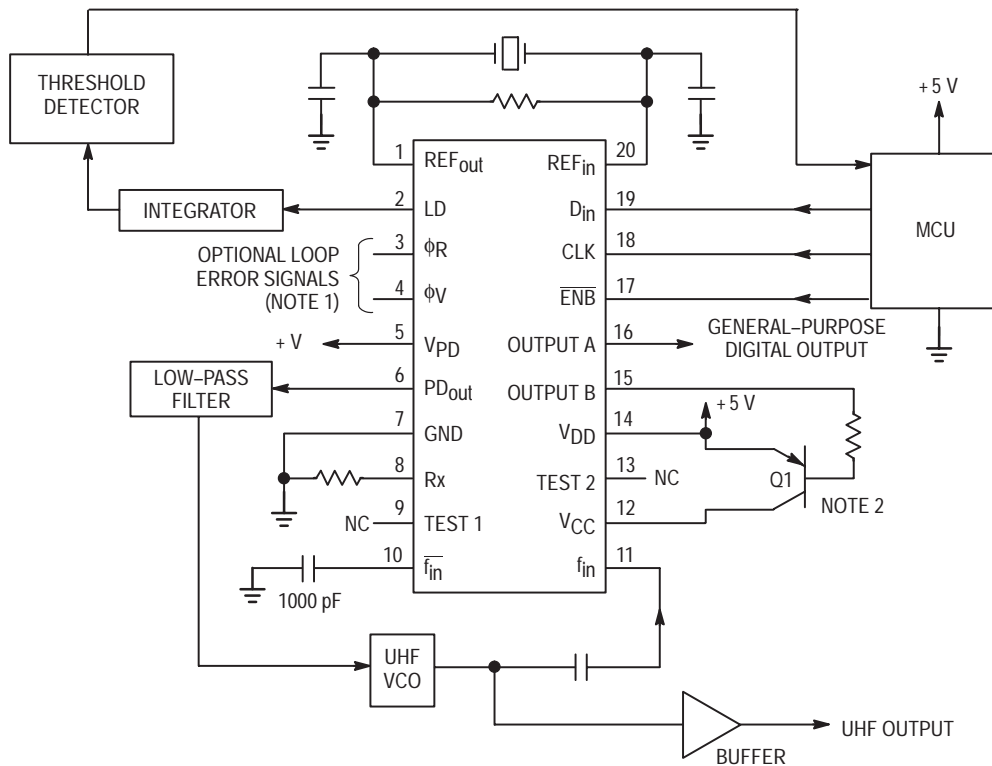

For a nominal design starting point, the user might consider a damping factor  $\zeta \approx 0.7$  and a natural loop frequency  $\omega_n \approx (2\pi f_R/50)$  where  $f_R$  is the frequency at the phase detector input. Larger  $\omega_n$  values result in faster loop lock times and, for similar sideband filtering, higher  $f_R$ -related VCO sidebands.

Either loop filter (A) or (B) is frequently followed by additional sideband filtering to further attenuate  $f_R$ -related VCO sidebands. This additional filtering may be active or passive.

**NOTES:**

1. When used, the  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information.
2. Transistor Q1 is required only if the standby feature is needed. Q1 permits the bipolar section of the device to be shut down via use of the general-purpose digital pin, OUTPUT B. If the standby feature is not needed, tie Pin 12 directly to the power supply.
3. For optimum performance, bypass the  $V_{CC}$ ,  $V_{DD}$ , and  $V_{PD}$  pins to GND with low-inductance capacitors.
4. The R counter is programmed for a divide value =  $REF_{in}/f_R$ . Typically,  $f_R$  is the tuning resolution required for the VCO. Also, the VCO frequency divided by  $f_R = N_T = N \times 64 + A$ ; this determines the values (N, A) that must be programmed into the N and A counters, respectively.

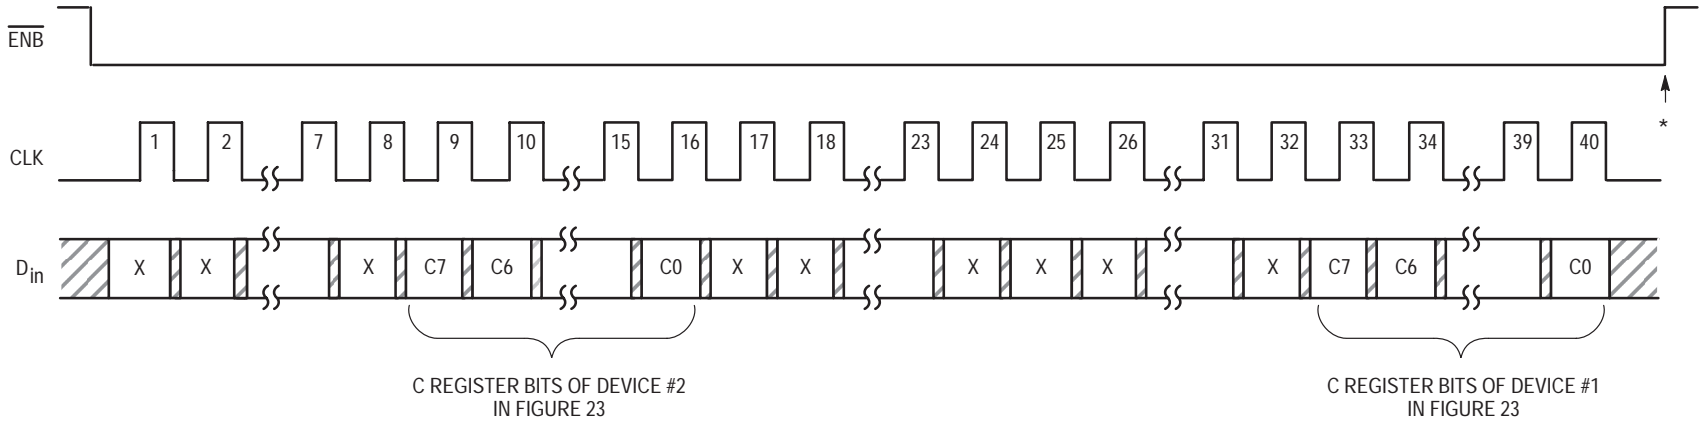

**Figure 22. Example Application**

NOTE: See related Figures 24 through 26; these bit streams apply to the MC145191 and MC145201.

**Figure 23. Cascading Two Devices**

Figure 24. Accessing the C Registers  
of Two Cascaded Devices

\*At this point, the new bytes are transferred to the C registers of both devices and stored. No other registers are affected.

Figure 25. Accessing the A Registers  
of Two Cascaded Devices

\*At this point, the new bytes are transferred to the A registers of both devices and stored. Additionally, for both devices, the 13 LSBs in each of the first buffers of the R registers are transferred to the respective R register's second buffer. Thus, the R, N, and A counters can be presented new divide ratios at the same time. The first buffer of each R register is not affected. Neither C register is affected.

Figure 26. Accessing the R Registers of Two Cascaded Devices

NOTES APPLICABLE TO EACH DEVICE:

1. At this point, bits R13, R14, and R15 are stored and sent to the "OSC or 4-Stage Divider" block in the Block Diagram. Bits R0 through R12 are loaded into the first buffer in the double-buffered section of the R register. Therefore, the R counter divide ratio is not altered yet and retains the previous ratio loaded. The C and A registers are not affected.
2. At this point, the bits R0 through R12 are transferred to the second buffer of the R register. The R counter begins dividing by the new ratio after completing the rest of the present count cycle. CLK must be low during the ENB pulse, as shown. Also, see note of Figure 25 for an alternate method of loading the second buffer in the R register. The C and A registers are not affected. The first buffer of the R register is not affected.

# Low-Voltage 2.0 GHz PLL Frequency Synthesizer

## Includes On-Board 64/65 Prescaler

The MC145202 is a low-voltage single-package synthesizer with serial interface capable of direct usage up to 2.0 GHz.

The counters are programmed via a synchronous serial port which is SPI compatible. The serial port is byte-oriented to facilitate control via an MCU. Due to the innovative BitGrabber Plus™ registers, the MC145202 may be cascaded with other peripherals featuring BitGrabber Plus without requiring leading dummy bits or address bits in the serial data stream. In addition, BitGrabber Plus peripherals may be cascaded with existing BitGrabber™ peripherals.

The device features a single-ended current source/sink phase detector A output and a double-ended phase detector B output. Both phase detectors have linear transfer functions (no dead zones). The maximum current of the single-ended phase detector output is determined by an external resistor tied from the Rx pin to ground. This current can be varied via the serial port.

Slew-rate control is provided by a special driver designed for the REF<sub>out</sub> pin. This minimizes interference caused by REF<sub>out</sub>.

This part includes a differential RF input that may be operated in a single-ended mode. Also featured are on-board support of an external crystal and a programmable reference output. The R, A, and N counters are fully programmable. The C register (configuration register) allows the part to be configured to meet various applications. A patented feature allows the C register to shut off unused outputs, thereby minimizing system noise and interference.

In order to have consistent lock times and prevent erroneous data from being loaded into the counters, on-board circuitry synchronizes the update of the A register if the A or N counters are loading. Similarly, an update of the R register is synchronized if the R counter is loading.

The double-buffered R register allows new divide ratios to be presented to the three counters (R, A, and N) simultaneously.

- Maximum Operating Frequency: 2000 MHz @ - 10 dBm
- Operating Supply Current: 4 mA Nominal at 3.0 V
- Operating Supply Voltage Range (V<sub>DD</sub> and V<sub>CC</sub> Pins): 2.7 to 5.5 V
- Operating Supply Voltage Range of Phase Detectors (V<sub>PD</sub> Pin): 2.7 to 5.5 V
- Current Source/Sink Phase Detector Output Capability: 1.7 mA @ 5.0 V  
1.0 mA @ 3.0 V
- Gain of Current Source/Sink Phase/Frequency Detector Controllable via Serial Port
- Operating Temperature Range: - 40 to + 85°C
- R Counter Division Range: 1 and 5 to 8191
- Dual-Modulus Capability Provides Total Division up to 262,143
- High-Speed Serial Interface: 4 Mbps
- OUTPUT A Pin, When Configured as Data Out, Permits Cascading of Devices
- Two General-Purpose Digital Outputs — OUTPUT A: Totem-Pole (Push-Pull) with Four Output Modes  
OUTPUT B: Open-Drain
- Patented Power-Saving Standby Feature with Orderly Recovery for Minimizing Lock Times, Standby Current: 30 μA

NOT RECOMMENDED FOR NEW DESIGN  
DEVICES TO BE PHASED OUT.  
Consider MC145202-1 for New Designs.

## BLOCK DIAGRAM

**SUPPLY CONNECTIONS:**

- PIN 12 =  $V_{CC}$  ( $V_+$  TO INPUT AMP AND 64/65 PRESCALER)
- PIN 5 =  $V_{PD}$  ( $V_+$  TO PHASE/FREQUENCY DETECTORS A AND B)
- PIN 14 =  $V_{DD}$  ( $V_+$  TO BALANCE OF CIRCUIT)
- PIN 7 = GND (COMMON GROUND)

**MAXIMUM RATINGS\*** (Voltages Referenced to GND, unless otherwise stated)

Symbol	Parameter	Value	Unit
V <sub>CC</sub> , V <sub>DD</sub>	DC Supply Voltage (Pins 12 and 14)	- 0.5 to + 6.0	V
V <sub>PD</sub>	DC Supply Voltage (Pin 5)	V <sub>DD</sub> - 0.5 to + 6.0	V
V <sub>in</sub>	DC Input Voltage	- 0.5 to V <sub>DD</sub> + 0.5	V
V <sub>out</sub>	DC Output Voltage (except OUTPUT B, PD <sub>out</sub> , φ <sub>R</sub> , φ <sub>V</sub> )	- 0.5 to V <sub>DD</sub> + 0.5	V
V <sub>out</sub>	DC Output Voltage (OUTPUT B, PD <sub>out</sub> , φ <sub>R</sub> , φ <sub>V</sub> )	- 0.5 to V <sub>PD</sub> + 0.5	V
I <sub>in</sub> , I <sub>PD</sub>	DC Input Current, per Pin (Includes V <sub>PD</sub> )	± 10	mA
I <sub>out</sub>	DC Output Current, per Pin	± 20	mA
I <sub>DD</sub>	DC Supply Current, V <sub>DD</sub> and GND Pins	± 30	mA
P <sub>D</sub>	Power Dissipation, per Package	300	mW
T <sub>stg</sub>	Storage Temperature	- 65 to + 150	°C
T <sub>L</sub>	Lead Temperature, 1 mm from Case for 10 Seconds	260	°C

\*Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit.

**ELECTRICAL CHARACTERISTICS**

(V<sub>DD</sub> = V<sub>CC</sub> = 2.7 to 5.5 V, Voltages Referenced to GND, unless otherwise stated; V<sub>PD</sub> = 2.7 to 5.5 V, T<sub>A</sub> = - 40 to 85°C)

Symbol	Parameter	Test Condition	Guaranteed Limit	Unit
V <sub>IL</sub>	Maximum Low-Level Input Voltage (D <sub>in</sub> , CLK, ENB)		0.3 x V <sub>DD</sub>	V
V <sub>IH</sub>	Minimum High-Level Input Voltage (D <sub>in</sub> , CLK, ENB)		0.7 x V <sub>DD</sub>	V

I <sub>OH</sub>	Minimum High-Level Output Current (OUTPUT A Only)	V <sub>out</sub> = V <sub>DD</sub> - 0.4 V V <sub>DD</sub> = 4.5 V	- 0.6	mA

(continued)

**ELECTRICAL CHARACTERISTICS** (continued)

Symbol	Parameter	Test Condition	Guaranteed Limit	Unit
$I_{in}$	Maximum Input Leakage Current ( $D_{in}$ , CLK, $\overline{ENB}$ , $REF_{in}$ )	$V_{in} = V_{DD}$ or GND, Device in XTAL Mode	$\pm 1.0$	$\mu A$
$I_{in}$	Maximum Input Current ( $REF_{in}$ )	$V_{in} = V_{DD}$ or GND, Device in Reference Mode	$\pm 100$	$\mu A$
$I_{OZ}$	Maximum Output Leakage Current ( $PD_{out}$ ) (OUTPUT B)	$V_{out} = V_{PD}$ or GND, Output in Floating State	$\pm 130$	nA
		$V_{out} = V_{PD}$ or GND, Output in High-Impedance State	$\pm 1$	$\mu A$
$I_{STBY}$	Maximum Standby Supply Current ( $V_{DD} + V_{PD}$ Pins)	$V_{in} = V_{DD}$ or GND; Outputs Open; Device in Standby Mode, Shut-Down Crystal Mode or $REF_{out}$ -Static-Low Reference Mode; OUTPUT B Controlling $V_{CC}$ per Figure 21	30	$\mu A$
$I_{PD}$	Maximum Phase Detector Quiescent Current ( $V_{PD}$ Pin)	Bit C6 = High Which Selects Phase Detector A, $PD_{out} =$ Open, $PD_{out} =$ Static State, Bit C4 = Low Which is <b>not</b> Standby, $I_{RX} = 170 \mu A$ , $V_{PD} = 5.5 V$	750	$\mu A$
		Bit C6 = Low Which Selects Phase Detector B, $\phi_R$ and $\phi_V =$ Open, $\phi_R$ and $\phi_V =$ Static Low or High, Bit C4 = Low Which is <b>not</b> Standby	30	
$I_T$	Total Operating Supply Current ( $V_{DD} + V_{PD} + V_{CC}$ Pins)	$f_{in} = 2.0 GHz$ ; $REF_{in} = 13 MHz @ 1 V_{p-p}$ ; OUTPUT A = Inactive and No Connect; $V_{DD} = V_{CC}$ , $REF_{out}$ , $\phi_V$ , $\phi_R$ , $PD_{out}$ , LD = No Connect; $D_{in}$ , $\overline{ENB}$ , CLK = $V_{DD}$ or GND, Phase Detector B Selected (Bit C6 = Low)	*	mA

\* The nominal values are:

4 mA at  $V_{DD} = 3.0 V$  and  $V_{PD} = 3.0 V$

6 mA at  $V_{DD} = 5.0 V$  and  $V_{PD} = 5.0 V$

These are not guaranteed limits.

**ANALOG CHARACTERISTICS — CURRENT SOURCE/SINK OUTPUT —  $PD_{out}$** 

( $I_{out} \leq 1 mA @ V_{DD} = 2.7 V$  and  $I_{out} \leq 1.7 mA @ V_{DD} \geq 4.5 V$ ,  $V_{DD} = V_{CC} = 2.7$  to  $5.5 V$ , Voltages Referenced to GND)

Parameter	Test Condition	$V_{PD}$	Guaranteed Limit	Unit
Maximum Source Current Variation (Part-to-Part)	$V_{out} = 0.5 \times V_{PD}$	2.7	$\pm 15$	%
		4.5	$\pm 15$	
		5.5	$\pm 15$	
Maximum Sink-vs-Source Mismatch (Note 3)	$V_{out} = 0.5 \times V_{PD}$	2.7	11	%
		4.5	11	
		5.5	11	
Output Voltage Range (Note 3)	$I_{out}$ Variation $\leq 15\%$	2.7	0.5 to 2.2	V
		4.5	0.5 to 3.7	
		5.5	0.5 to 4.7	

**NOTES:**

- Percentages calculated using the following formula: (Maximum Value – Minimum Value)/Maximum Value.
- See Rx Pin Description for external resistor values.
- This parameter is guaranteed for a given temperature within  $-40$  to  $+85^\circ C$ .

## AC INTERFACE CHARACTERISTICS

( $V_{DD} = V_{CC} = 2.7$  to  $5.5$  V,  $T_A = -40$  to  $+85^\circ\text{C}$ ,  $C_L = 25$  pF, Input  $t_r = t_f = 10$  ns;  $V_{PD} = 2.7$  to  $5.5$  V)

Symbol	Parameter	Figure No.	Guaranteed Limit	Unit
$f_{\text{clk}}$	Serial Data Clock Frequency (Note: Refer to Clock $t_w$ below)	1	dc to 4.0	MHz
$t_{\text{PLH}}, t_{\text{PHL}}$	Maximum Propagation Delay, CLK to OUTPUT A (Selected as Data Out)	1, 5	100	ns
$t_{\text{PLH}}, t_{\text{PHL}}$	Maximum Propagation Delay, $\overline{\text{ENB}}$ to OUTPUT A (Selected as Port)	2, 5	150	ns
$t_{\text{PZL}}, t_{\text{PLZ}}$	Maximum Propagation Delay, $\overline{\text{ENB}}$ to OUTPUT B	2, 6	150	ns
$t_{\text{TLH}}, t_{\text{THL}}$	Maximum Output Transition Time, OUTPUT A and OUTPUT B; $t_{\text{THL}}$ only, on OUTPUT B	1, 5, 6	50	ns
$C_{\text{in}}$	Maximum Input Capacitance – $D_{\text{in}}$ , $\overline{\text{ENB}}$ , CLK		10	pF

## TIMING REQUIREMENTS

( $V_{DD} = V_{CC} = 2.7$  to  $5.5$  V,  $T_A = -40$  to  $+85^\circ\text{C}$ , Input  $t_r = t_f = 10$  ns, unless otherwise indicated)

Symbol	Parameter	Figure No.	Guaranteed Limit	Unit
$t_{\text{su}}, t_{\text{h}}$	Minimum Setup and Hold Times, $D_{\text{in}}$ vs CLK	3	50	ns
$t_{\text{su}}, t_{\text{h}}, t_{\text{rec}}$	Minimum Setup, Hold and Recovery Times, $\overline{\text{ENB}}$ vs CLK	4	100	ns
$t_w$	Minimum Pulse Width, $\overline{\text{ENB}}$	4	*	cycles
$t_w$	Minimum Pulse Width, CLK	1	125	ns
$t_r, t_f$	Maximum Input Rise and Fall Times, CLK	1	100	$\mu\text{s}$

\* The minimum limit is  $3 \text{ REF}_{\text{in}}$  cycles or  $195 f_{\text{in}}$  cycles, whichever is greater.

## PIN DESCRIPTIONS

### DIGITAL INTERFACE PINS

#### D<sub>in</sub> Serial Data Input (Pin 19)

The bit stream begins with the most significant bit (MSB) and is shifted in on the low-to-high transition of CLK. The bit pattern is 1 byte (8 bits) long to access the C or configuration register, 2 bytes (16 bits) to access the first buffer of the R register, or 3 bytes (24 bits) to access the A register (see Table 3). The values in the C, R, and A registers do not change during shifting because the transfer of data to the registers is controlled by  $\overline{\text{ENB}}$ .

#### CAUTION

The value programmed for the N counter must be greater than or equal to the value of the A counter.

The 13 least significant bits (LSBs) of the R register are double-buffered. As indicated above, data is latched into the first buffer on a 16-bit transfer. (The 3 MSBs are not double-buffered and have an immediate effect after a 16-bit transfer.) The second buffer of the R register contains the 13 bits for the R counter. This second buffer is loaded with the contents of the first buffer when the A register is loaded (a 24-bit transfer). This allows presenting new values to the R, A, and N counters simultaneously. If this is not required, then the 16-bit transfer may be followed by pulsing  $\overline{\text{ENB}}$  low with no signal on the CLK pin. This is an alternate method of transferring data to the second buffer of the R register (see Figure 16).

The bit stream needs neither address nor steering bits due to the innovative BitGrabber Plus registers. Therefore, all bits in the stream are available to be data for the three registers. Random access of any register is provided (i.e., the registers may be accessed in any sequence). Data is retained in the registers over a supply range of 2.7 to 5.5 V. The formats are shown in Figures 14, 15, and 16.

D<sub>in</sub> typically switches near 50% of V<sub>DD</sub> to maximize noise immunity. This input can be directly interfaced to CMOS devices with outputs guaranteed to switch near rail-to-rail. When interfacing to NMOS or TTL devices, either a level shifter (MC74HC14A, MC14504B) or pull-up resistor of 1 k $\Omega$  to 10 k $\Omega$  must be used. Parameters to consider when sizing the resistor are worst-case I<sub>OL</sub> of the driving device, maximum tolerable power consumption, and maximum data rate.

**Table 3. Register Access**

(MSBs are shifted in first; C0, R0, and A0 are the LSBs)

Number of Clocks	Accessed Register	Bit Nomenclature
8	C Register	C7, C6, C5, . . . , C0
16	R Register	R15, R14, R13, . . . , R0
24	A Register	A23, A22, A21, . . . , A0
Other Values $\leq$ 32 Values > 32	Not Allowed See Figures 22 – 25	

### CLK

#### Serial Data Clock Input (Pin 18)

Low-to-high transitions on CLK shift bits available at the D<sub>in</sub> pin, while high-to-low transitions shift bits from OUTPUT A (when configured as Data Out, see Pin 16). The 24-1/2-stage shift register is static, allowing clock rates down to dc in a continuous or intermittent mode.

Eight clock cycles are required to access the C register. Sixteen clock cycles are needed for the first buffer of the R register. Twenty-four cycles are used to access the A register. See Table 3 and Figures 14, 15, and 16. The number of clocks required for cascaded devices is shown in Figures 23 through 25.

CLK typically switches near 50% of V<sub>DD</sub> and has a Schmitt-triggered input buffer. Slow CLK rise and fall times are allowed. See the last paragraph of D<sub>in</sub> for more information.

#### NOTE

To guarantee proper operation of the power-on reset (POR) circuit, the CLK pin must be held at GND (with  $\overline{\text{ENB}}$  being a don't care) or  $\overline{\text{ENB}}$  must be held at the potential of the V+ pin (with CLK being a don't care) during power-up. Floating, toggling, or having these pins in the wrong state during power-up does not harm the chip, but causes two potentially undesirable effects. First, the outputs of the device power up in an unknown state. Second, if two devices are cascaded, the A Registers must be written twice after power up. After these two accesses, the two cascaded chips perform normally.

### $\overline{\text{ENB}}$

#### Active Low Enable Input (Pin 17)

This pin is used to activate the serial interface to allow the transfer of data to/from the device. When  $\overline{\text{ENB}}$  is in an inactive high state, shifting is inhibited and the port is held in the initialized state. To transfer data to the device,  $\overline{\text{ENB}}$  (which must start inactive high) is taken low, a serial transfer is made via D<sub>in</sub> and CLK, and  $\overline{\text{ENB}}$  is taken back high. The low-to-high transition on  $\overline{\text{ENB}}$  transfers data to the C or A registers and first buffer of the R register, depending on the data stream length per Table 3.

Transitions on  $\overline{\text{ENB}}$  must not be attempted while CLK is high. This puts the device out of synchronization with the microcontroller. Resynchronization occurs when  $\overline{\text{ENB}}$  is high and CLK is low.

This input is also Schmitt-triggered and switches near 50% of V<sub>DD</sub>, thereby minimizing the chance of loading erroneous data into the registers. See the last paragraph of D<sub>in</sub> for more information.

For POR information, see the note for the CLK pin.

## OUTPUT A

### Configurable Digital Output (Pin 16)

OUTPUT A is selectable as  $f_R$ ,  $f_V$ , Data Out, or Port. Bits A22 and A23 in the A register control the selection; see Figure 15.

If A23 = A22 = high, OUTPUT A is configured as  $f_R$ . This signal is the buffered output of the 13-stage R counter. The  $f_R$  signal appears as normally low and pulses high. The  $f_R$  signal can be used to verify the divide ratio of the R counter. This ratio extends from 5 to 8191 and is determined by the binary value loaded into bits R0–R12 in the R register. Also, direct access to the phase detectors via the  $REF_{IN}$  pin is allowed by choosing a divide value of 1 (see Figure 16). The maximum frequency at which the phase detectors operate is 2 MHz. Therefore, the frequency of  $f_R$  should not exceed 2 MHz.

If A23 = high and A22 = low, OUTPUT A is configured as  $f_V$ . This signal is the buffered output of the 12-stage N counter. The  $f_V$  signal appears as normally low and pulses high. The  $f_V$  signal can be used to verify the operation of the prescaler, A counter, and N counter. The divide ratio between the  $f_{IN}$  input and the  $f_V$  signal is  $N \times 64 + A$ . N is the divide ratio of the N counter and A is the divide ratio of the A counter. These ratios are determined by bits loaded into the A register. See Figure 15. The maximum frequency at which the phase detectors operate is 2 MHz. Therefore, the frequency of  $f_V$  should not exceed 2 MHz.

If A23 = low and A22 = high, OUTPUT A is configured as Data Out. This signal is the serial output of the 24–1/2-stage shift register. The bit stream is shifted out on the high-to-low transition of the CLK input. Upon power up, OUTPUT A is automatically configured as Data Out to facilitate cascading devices.

If A23 = A22 = low, OUTPUT A is configured as Port. This signal is a general-purpose digital output which may be used as an MCU port expander. This signal is low when the Port bit (C1) of the C register is low, and high when the Port bit is high.

## OUTPUT B

### Open-Drain Digital Output (Pin 15)

This signal is a general-purpose digital output which may be used as an MCU port expander. This signal is low when the Out B bit (C0) of the C register is low. When the Out B bit is high, OUTPUT B assumes the high-impedance state. OUTPUT B may be pulled up through an external resistor or active circuitry to any voltage less than or equal to the potential of the  $V_{PD}$  pin. **Note:** the maximum voltage allowed on the  $V_{PD}$  pin is 5.5 V.

Upon power-up, power-on reset circuitry forces OUTPUT B to a low level.

## REFERENCE PINS

### $REF_{IN}$ and $REF_{OUT}$

#### Reference Input and Reference Output (Pins 20 and 1)

Configurable pins for a Crystal or an External Reference. This pair of pins can be configured in one of two modes: the crystal mode or the reference mode. Bits R13, R14, and R15 in the R register control the modes as shown in Figure 16.

In crystal mode, these pins form a reference oscillator when connected to terminals of an external parallel-reso-

nant crystal. Frequency-setting capacitors of appropriate values, as recommended by the crystal supplier, are connected from each of the two pins to ground (up to a maximum of 30 pF each, including stray capacitance). An external resistor of 1 M $\Omega$  to 15 M $\Omega$  is connected directly across the pins to ensure linear operation of the amplifier. The required connections for the components are shown in Figure 9.

To turn on the oscillator, bits R15, R14, and R13 must have an octal value of one (001 in binary, respectively). This is the active-crystal mode shown in Figure 16. In this mode, the crystal oscillator runs and the R Counter divides the crystal frequency, unless the part is in standby. If the part is placed in standby via the C register, the oscillator runs, but the R counter is stopped. However, if bits R15 to R13 have a value of 0, the oscillator is stopped, which saves additional power. This is the shut-down crystal mode (shown in Figure 16) and can be engaged whether in standby or not.

In the reference mode,  $REF_{IN}$  (Pin 20) accepts a signal from an external reference oscillator, such as a TCXO. A signal swinging from at least the  $V_{IL}$  to  $V_{IH}$  levels listed in the Electrical Characteristics table may be directly coupled to the pin. If the signal is less than this level, ac coupling must be used as shown in Figure 8. Due to an on-board resistor which is engaged in the reference modes, an external biasing resistor tied between  $REF_{IN}$  and  $REF_{OUT}$  is not required.

With the reference mode, the  $REF_{OUT}$  pin is configured as the output of a divider. As an example, if bits R15, R14, and R13 have an octal value of seven, the frequency at  $REF_{OUT}$  is the  $REF_{IN}$  frequency divided by 16. In addition, Figure 16 shows how to obtain ratios of eight, four, and two. A ratio of one-to-one can be obtained with an octal value of three. Upon power up, a ratio of eight is automatically initialized. The maximum frequency capability of the  $REF_{OUT}$  pin is listed in the Loop Specifications table for an output swing of 1 V p-p and 20 pF loads. Therefore, for higher  $REF_{IN}$  frequencies, the one-to-one ratio may not be used for this magnitude of signal swing and loading requirements. Likewise, for  $REF_{IN}$  frequencies above two times the highest rated frequency, the ratio must be more than two.

The output has a special on-board driver that has slew-rate control. This feature minimizes interference in the application.

If  $REF_{OUT}$  is unused, an octal value of two should be used for R15, R14, and R13 and the  $REF_{OUT}$  pin should be floated. A value of two allows  $REF_{IN}$  to be functional while disabling  $REF_{OUT}$ , which minimizes dynamic power consumption.

## LOOP PINS

### $f_{IN}$ and $\overline{f_{IN}}$ Frequency Inputs (Pins 11 and 10)

These pins are frequency inputs from the VCO. These pins feed the on-board RF amplifier which drives the 64/65 prescaler. These inputs may be fed differentially. However, they are usually used in a single-ended configuration (shown in Figure 7). Note that  $f_{IN}$  is driven while  $\overline{f_{IN}}$  must be tied to ground via a capacitor.

Motorola does not recommend driving  $\overline{f_{IN}}$  while terminating  $f_{IN}$  because this configuration is not tested for sensitivity. The sensitivity is dependent on the frequency as shown in the Loop Specifications table.

## PD<sub>out</sub> Single-Ended Phase/Frequency Detector Output (Pin 6)

This is a three-state current-source/sink output for use as a loop error signal when combined with an external low-pass filter. The phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 17.

POL bit (C7) in the C register = low (see Figure 14)

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ : current-sinking pulses from a floating state

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ : current-sourcing pulses from a floating state

Frequency and Phase of  $f_V = f_R$ : essentially a floating state; voltage at pin determined by loop filter

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ : current-sourcing pulses from a floating state

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ : current-sinking pulses from a floating state

Frequency and Phase of  $f_V = f_R$ : essentially a floating state; voltage at pin determined by loop filter

This output can be enabled, disabled, and inverted via the C register. If desired, PD<sub>out</sub> can be forced to the high-impedance state by utilization of the disable feature in the C register (bit C6). This is a patented feature. Similarly, PD<sub>out</sub> is forced to the high-impedance state when the device is put into standby (STBY bit C4 = high).

The PD<sub>out</sub> circuit is powered by V<sub>PD</sub>. The phase detector gain is controllable by bits C3, C2, and C1: gain (in amps per radian) = PD<sub>out</sub> current divided by  $2\pi$ .

## $\phi_R$ and $\phi_V$ (Pins 3 and 4) Double-Ended Phase/Frequency Detector Outputs

These outputs can be combined externally to generate a loop error signal. Through use of a Motorola patented technique, the detector's dead zone has been eliminated. Therefore, the phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 17.

POL bit (C7) in the C register = low (see Figure 14)

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_V =$  negative pulses,  $\phi_R =$  essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_V =$  essentially high,  $\phi_R =$  negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

POL bit (C7) = high

Frequency of  $f_V > f_R$  or Phase of  $f_V$  Leading  $f_R$ :  $\phi_R =$  negative pulses,  $\phi_V =$  essentially high

Frequency of  $f_V < f_R$  or Phase of  $f_V$  Lagging  $f_R$ :  $\phi_R =$  essentially high,  $\phi_V =$  negative pulses

Frequency and Phase of  $f_V = f_R$ :  $\phi_V$  and  $\phi_R$  remain essentially high, except for a small minimum time period when both pulse low in phase

These outputs can be enabled, disabled, and interchanged via C register bits C6 or C4. This is a patented fea-

ture. Note that when disabled or in standby,  $\phi_R$  and  $\phi_V$  are forced to their rest condition (high state).

The  $\phi_R$  and  $\phi_V$  output signal swing is approximately from GND to V<sub>PD</sub>.

## LD Lock Detector Output (Pin 2)

This output is essentially at a high level with narrow low-going pulses when the loop is locked ( $f_R$  and  $f_V$  of the same phase and frequency). The output pulses low when  $f_V$  and  $f_R$  are out of phase or different frequencies. LD is the logical ANDing of  $\phi_R$  and  $\phi_V$  (see Figure 17).

This output can be enabled and disabled via the C register. This is a patented feature. Upon power up, on-chip initialization circuitry disables LD to a static low logic level to prevent a false "lock" signal. If unused, LD should be disabled and left open.

The LD output signal swing is approximately from GND to V<sub>DD</sub>.

## Rx External Resistor (Pin 8)

A resistor tied between this pin and GND, in conjunction with bits in the C register, determines the amount of current that the PD<sub>out</sub> pin sinks and sources. When bits C2 and C3 are both set high, the maximum current is obtained at PD<sub>out</sub>; see Tables 4 and 5 for other current values. The recommended value for Rx is 3.9 k $\Omega$ . A value of 3.9 k $\Omega$  provides current at the PD<sub>out</sub> pin of approximately 1 mA @ V<sub>DD</sub> = 3 V and approximately 1.7 mA @ V<sub>DD</sub> = 5 V in the 100% current mode. Note that V<sub>DD</sub>, not V<sub>PD</sub>, is a factor in determining the current.

When the  $\phi_R$  and  $\phi_V$  outputs are used, the Rx pin may be floated.

**Table 4. PD<sub>out</sub> Current\*, C1 = Low with OUTPUT A not Selected as "Port"; Also, Default Mode When OUTPUT A Selected as "Port"**

Bit C3	Bit C2	PD <sub>out</sub> Current*
0	0	70%
0	1	80%
1	0	90%
1	1	100%

\* At the time the data sheet was printed, only the 100% current mode was guaranteed. The reduced current modes were for experimentation only.

**Table 5. PD<sub>out</sub> Current\*, C1 = High with OUTPUT A not Selected as "Port"**

Bit C3	Bit C2	PD <sub>out</sub> Current*
0	0	25%
0	1	50%
1	0	75%
1	1	100%

\* At the time the data sheet was printed, only the 100% current mode was guaranteed. The reduced current modes were for experimentation only.

## TEST POINT PINS

### TEST 1

#### Modulus Control Signal (Pin 9)

This pin may be used in conjunction with the Test 2 pin for access to the on-board 64/65 prescaler. When Test 1 is low, the prescaler divides by 65. When high, the prescaler divides by 64.

#### CAUTION

This pin is an unbuffered output and must be floated in an actual application. This pin must be attached to an isolated pad with no trace.

### TEST 2

#### Prescaler Output (Pin 13)

This pin may be used to access the on-board 64/65 prescaler output.

#### CAUTION

This pin is an unbuffered output and must be floated in an actual application. This pin must be attached to an isolated pad with no trace.

## POWER SUPPLY PINS

### VDD

#### Positive Power Supply (Pin 14)

This pin supplies power to the main CMOS digital portion of the device. Also, this pin, in conjunction with the Rx resistor, determines the internal reference current for the PD<sub>out</sub> pin. The voltage range is +2.7 to +5.5 V with respect to the GND pin.

For optimum performance, V<sub>DD</sub> should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

### VCC

#### Positive Power Supply (Pin 12)

This pin supplies power to the RF amp and 64/65 prescaler. The voltage range is +2.7 to +5.5 V with respect to the GND pin. In standby mode, the V<sub>CC</sub> pin still draws a few milliamps from the power supply. This current drain can be eliminated with the use of transistor Q1 as shown in Figure 21.

For optimum performance, V<sub>CC</sub> should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

### V<sub>PD</sub>

#### Positive Power Supply (Pin 5)

This pin supplies power to both phase/frequency detectors A and B. The voltage applied on this pin may be more or less than the potential applied to the V<sub>DD</sub> and V<sub>CC</sub> pins. The voltage range for V<sub>PD</sub> is 2.7 to 5.5 V with respect to the GND pin.

For optimum performance, V<sub>PD</sub> should be bypassed to GND using a low-inductance capacitor mounted very close to these pins. Lead lengths on the capacitor should be minimized.

### GND

#### Ground (Pin 7)

Common ground.

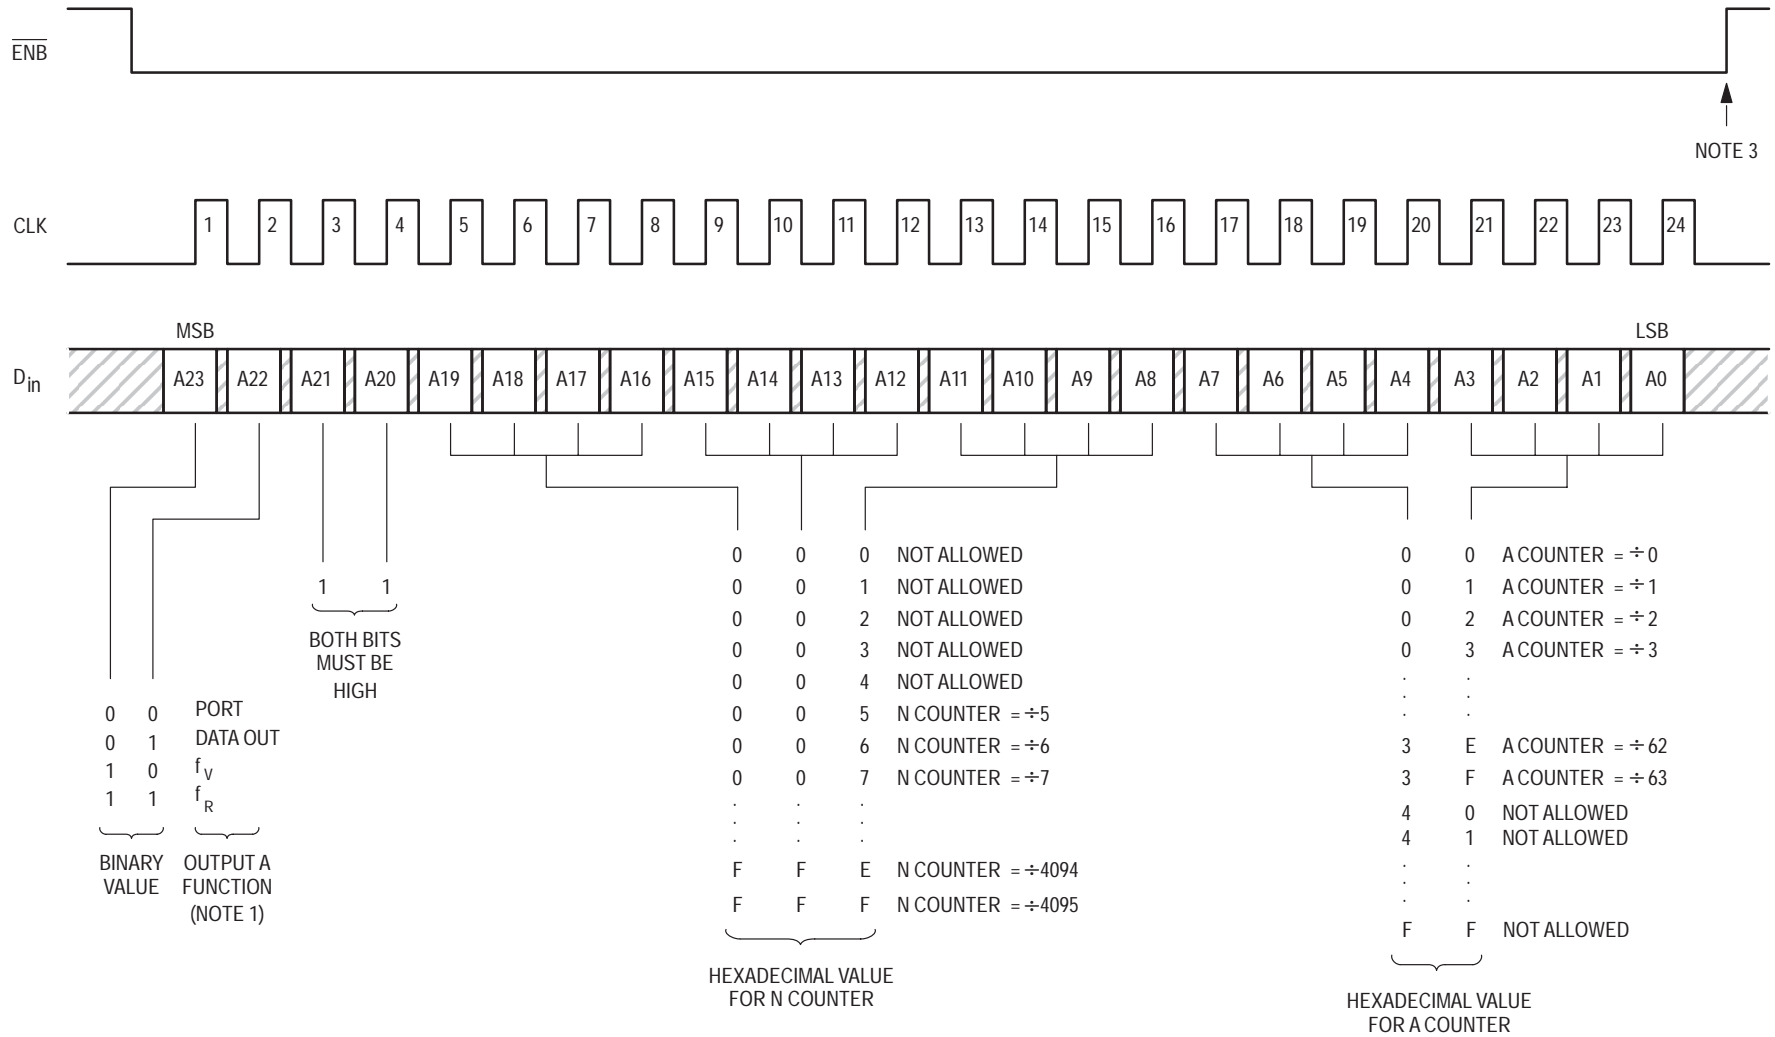

\* At this point, the new byte is transferred to the C register and stored. No other registers are affected.

- C7 – POL: Selects the output polarity of the phase/frequency detectors. When set high, this bit inverts PD<sub>Out</sub> and interchanges the  $\phi_R$  function with  $\phi_V$  as depicted in Figure 17. Also see the phase detector output pin descriptions for more information. This bit is cleared low at power up.
- C6 – PDA/B: Selects which phase/frequency detector is to be used. When set high, enables the output of phase/frequency detector A (PD<sub>Out</sub>) and disables phase/frequency detector B by forcing  $\phi_R$  and  $\phi_V$  to the static high state. When cleared low, phase/frequency detector B is enabled ( $\phi_R$  and  $\phi_V$ ) and phase/frequency detector A is disabled with PD<sub>Out</sub> forced to the high-impedance state. This bit is cleared low at power up.
- C5 – LDE: Enables the lock detector output when set high. When the bit is cleared low, the LD output is forced to a static low level. This bit is cleared low at power up.
- C4 – STBY: When set, places the CMOS section of device, which is powered by the V<sub>DD</sub> and V<sub>PD</sub> pins, in the standby mode for reduced power consumption: PD<sub>Out</sub> is forced to the high-impedance state,  $\phi_R$  and  $\phi_V$  are forced high, the A, N, and R counters are inhibited from counting, and the Rx current is shut off. In standby, the state of LD is determined by bit C5. C5 low forces LD low (no change). C5 high forces LD static high. During standby, data is retained in the A, R, and C registers. The condition of REF/OSC circuitry is determined by the control bits in the R register: R13, R14, and R15. However, if REF<sub>Out</sub> = static low is selected, the internal feedback resistor is disconnected and the input is inhibited when in standby; in addition, the REF<sub>in</sub> input only presents a capacitive load. NOTE: Standby does not affect the other modes of the REF/OSC circuitry.  
  
When C4 is reset low, the part is taken out of standby in two steps. First, the REF<sub>in</sub> (only in one mode) resistor is reconnected, all counters are enabled, and the Rx current is enabled. Any  $f_R$  and  $f_V$  signals are inhibited from toggling the phase/frequency detectors and lock detector. Second, when the first  $f_V$  pulse occurs, the R counter is jam loaded, and the phase/frequency and lock detectors are initialized. Immediately after the jam load, the A, N, and R counters begin counting down together. At this point, the  $f_R$  and  $f_V$  pulses are enabled to the phase and lock detectors. (Patented feature.)
- C3, C2 – I2, I1: Controls the PD<sub>Out</sub> source/sink current per Tables 4 and 5. With both bits high, the maximum current is available. Also, see C1 bit description.
- C1 – Port: When the OUTPUT A pin is selected as “Port” via bits A22 and A23, C1 determines the state of OUTPUT A. When C1 is set high, OUTPUT A is forced high; C1 low forces OUTPUT A low. When OUTPUT A is *not* selected as “Port,” C1 controls whether the PD<sub>Out</sub> step size is 10% or 25%. (See Tables 4 and 5.) When low, steps are 10%. When high, steps are 25%. Default is 10% steps when OUTPUT A is selected as “Port.” The Port bit is not affected by the standby mode.
- C0 – Out B: Determines the state of OUTPUT B. When C0 is set high, OUTPUT B is high-impedance; C0 low forces OUTPUT B low. The Out B bit is not affected by the standby mode. This bit is cleared low at power up.

**Figure 14. C Register Access and Format (8 Clock Cycles are Used)**

Figure 15. A Register Access and Format (24 Clock Cycles are Used)

NOTES:

- Bits R15 through R13 control the configurable “OSC or 4–stage divider” block (see Block Diagram).
- Bits R12 through R0 control the “13–stage R counter” block (see Block Diagram).
- A power–on initialize circuit forces a default REF<sub>in</sub> to REF<sub>out</sub> ratio of eight.
- At this point, bits R13, R14, and R15 are stored and sent to the “OSC or 4–Stage Divider” block in the Block Diagram. Bits R0 – R12 are loaded into the first buffer in the double–buffered section of the R register. Therefore, the R counter divide ratio is not altered yet and retains the previous ratio loaded. The C and A registers are not affected.
- Optional load pulse. At this point, bits R0 – R12 are transferred to the second buffer of the R register. The R counter begins dividing by the new ratio after completing the rest of the present count cycle. CLK must be low during the ENB pulse, as shown. The C and A registers are not affected. The first buffer of the R register is not affected. Also, see note 3 of Figure 15 for an alternate method of loading the second buffer in the R register.
- Allows direct access to reference input of phase/frequency detectors.

Figure 16. R Register Access and Format (16 Clock Cycles are Used)

V<sub>H</sub> = High voltage level

V<sub>L</sub> = Low voltage level

\*At this point, when both f<sub>R</sub> and f<sub>V</sub> are in phase, the output source and sink circuits are turned on for a short interval.

NOTE: The PD<sub>out</sub> either sources or sinks current during out-of-lock conditions. When locked in phase and frequency, the output is in the floating condition and the voltage at that pin is determined by the low-pass filter capacitor. PD<sub>out</sub>, φ<sub>R</sub>, and φ<sub>V</sub> are shown with the polarity bit (POL) = low; see Figure 14 for POL.

**Figure 17. Phase/Frequency Detectors and Lock Detector Output Waveforms**

## DESIGN CONSIDERATIONS

### CRYSTAL OSCILLATOR CONSIDERATIONS

The following options may be considered to provide a reference frequency to Motorola's CMOS frequency synthesizers.

#### Use of a Hybrid Crystal Oscillator

Commercially available temperature-compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide very stable reference frequencies. An oscillator capable of CMOS logic levels at the output may be direct or dc coupled to REF<sub>in</sub>. If the oscillator does not have CMOS logic levels on the outputs, capacitive or ac coupling to REF<sub>in</sub> may be used (see Figure 8).

For additional information about TCXOs and data clock oscillators, please consult the latest version of the *eem Electronic Engineers Master Catalog*, the *Gold Book*, or similar publications.

#### Design an Off-Chip Reference

The user may design an off-chip crystal oscillator using discrete transistors or ICs specifically developed for crystal oscillator applications, such as the MC12061 MECL device. The reference signal from the MECL device is ac coupled to REF<sub>in</sub> (see Figure 8). For large amplitude signals (standard CMOS logic levels), dc coupling may be used.

#### Use of the On-Chip Oscillator Circuitry

The on-chip amplifier (a digital inverter) along with an appropriate crystal may be used to provide a reference source frequency. A fundamental mode crystal, parallel resonant at the desired operating frequency, should be connected as shown in Figure 18.

The crystal should be specified for a loading capacitance (C<sub>L</sub>) which does not exceed approximately 20 pF when used at the highest operating frequencies listed in the Loop Specifications table. Assuming R1 = 0 Ω, the shunt load capacitance (C<sub>L</sub>) presented across the crystal can be estimated to be:

$$C_L = \frac{C_{in}C_{out}}{C_{in} + C_{out}} + C_a + C_{stray} + \frac{C1 \cdot C2}{C1 + C2}$$

where

C<sub>in</sub> = 5 pF (see Figure 19)

C<sub>out</sub> = 6 pF (see Figure 19)

C<sub>a</sub> = 1 pF (see Figure 19)

C1 and C2 = external capacitors (see Figure 18)

C<sub>stray</sub> = the total equivalent external circuit stray capacitance appearing across the crystal terminals

The oscillator can be "trimmed" on-frequency by making a portion or all of C1 variable. The crystal and associated components must be located as close as possible to the REF<sub>in</sub> and REF<sub>out</sub> pins to minimize distortion, stray capacitance, stray inductance, and startup stabilization time. Circuit stray capacitance can also be handled by adding the appropriate stray value to the values for C<sub>in</sub> and C<sub>out</sub>. For this approach, the term C<sub>stray</sub> becomes 0 in the above expression for C<sub>L</sub>.

Power is dissipated in the effective series resistance of the crystal, R<sub>e</sub>, in Figure 20. The maximum drive level specified

by the crystal manufacturer represents the maximum stress that the crystal can withstand without damage or excessive shift in operating frequency. R1 in Figure 18 limits the drive level. The use of R1 is not necessary in most cases.

To verify that the maximum dc supply voltage does not cause the crystal to be overdriven, monitor the output frequency (f<sub>R</sub>) at OUTPUT A as a function of supply voltage. (REF<sub>out</sub> is not used because loading impacts the oscillator.) The frequency should increase very slightly as the dc supply voltage is increased. An overdriven crystal decreases in frequency or becomes unstable with an increase in supply voltage. The operating supply voltage must be reduced or R1 must be increased in value if the overdriven condition exists. The user should note that the oscillator start-up time is proportional to the value of R1.

Through the process of supplying crystals for use with CMOS inverters, many crystal manufacturers have developed expertise in CMOS oscillator design with crystals. Discussions with such manufacturers can prove very helpful (see Table NO TAG).

\* May be needed in certain cases. See text.

## PHASE-LOCKED LOOP — LOW-PASS FILTER DESIGN

(A)

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC}}$$

$$\zeta = \frac{R}{2} \sqrt{\frac{K_\phi K_{VCO} C}{N}} = \frac{\omega_n RC}{2}$$

$$Z(s) = \frac{1 + sRC}{sC}$$

NOTE:

For (A), using  $K_\phi$  in amps per radian with the filter's impedance transfer function,  $Z(s)$ , maintains units of volts per radian for the detector/filter combination. Additional sideband filtering can be accomplished by adding a capacitor  $C'$  across  $R$ . The corner  $\omega_c = 1/RC'$  should be chosen such that  $\omega_n$  is not significantly affected.

(B)

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NCR_1}}$$

$$\zeta = \frac{\omega_n R_2 C}{2}$$

ASSUMING GAIN A IS VERY LARGE, THEN:

$$F(s) = \frac{R_2 s C + 1}{R_1 s C}$$

NOTE:

For (B),  $R_1$  is frequently split into two series resistors; each resistor is equal to  $R_1$  divided by 2. A capacitor  $C_C$  is then placed from the midpoint to ground to further filter the error pulses. The value of  $C_C$  should be such that the corner frequency of this network does not significantly affect  $\omega_n$ .

DEFINITIONS:

$N$  = Total Division Ratio in Feedback Loop

$K_\phi$  (Phase Detector Gain) =  $I_{PD_{out}}/2\pi$  amps per radian for  $PD_{out}$

$K_\phi$  (Phase Detector Gain) =  $V_{PD}/2\pi$  volts per radian for  $\phi_V$  and  $\phi_R$

$K_{VCO}$  (VCO Transfer Function) =  $\frac{2\pi\Delta f_{VCO}}{\Delta V_{VCO}}$  radians per volt

For a nominal design starting point, the user might consider a damping factor  $\zeta \approx 0.7$  and a natural loop frequency  $\omega_n \approx (2\pi f_R/50)$  where  $f_R$  is the frequency at the phase detector input. Larger  $\omega_n$  values result in faster loop lock times and, for similar sideband filtering, higher  $f_R$ -related VCO sidebands.

Either loop filter (A) or (B) is frequently followed by additional sideband filtering to further attenuate  $f_R$ -related VCO sidebands. This additional filtering may be active or passive.

**NOTES:**

1. When used, the  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information.
2. Transistor Q1 is required only if the standby feature is needed. Q1 permits the bipolar section of the device to be shut down via use of the general-purpose digital pin, OUTPUT B. If the standby feature is not needed, tie Pin 12 directly to the power supply.
3. For optimum performance, bypass the  $V_{CC}$ ,  $V_{DD}$ , and  $V_{PD}$  pins to GND with low-inductance capacitors.
4. The R counter is programmed for a divide value =  $REF_{in} / f_R$ . Typically,  $f_R$  is the tuning resolution required for the VCO. Also, the VCO frequency divided by  $f_R = N_T = N \times 64 + A$ ; this determines the values (N, A) that must be programmed into the N and A counters, respectively.

**Figure 21. Example Application**

NOTE: See related Figures 23, 24, and 25.

**Figure 22. Cascading Two Devices**

Figure 25. Accessing the R Registers of Two Cascaded  
MC145202 Devices

NOTES APPLICABLE TO EACH DEVICE:

1. At this point, bits R13, R14 and R15 are stored and sent to the “OSC or 4–Stage Divider” block in the Block Diagram. Bits R0 through R12 are loaded into the first buffer in the double–buffered section of the R register. Therefore, the R counter divide is not altered yet and retains the previous ratio loaded. The C and A registers are not affected.
2. Optional load pulse. At this point, the bits R0 through R12 are transferred to the second buffer of the R register. The R counter begins dividing by the new ratio after completing the rest of the present count cycle. CLK must be low during the ENB pulse, as shown. The C and A registers are not affected. The first buffer of the R register is not affected. Also, see note of Figure 24 for an alternate method of loading the second buffer in the R register.

# Product Preview

## 2.0 GHz PLL Frequency Synthesizer

The MC145202-1 is pin-for-pin compatible with the previous generation MC145200, MC145201, and MC145202. Table 1 highlights the different features in these four devices. The MC145202-1 is recommended for new designs, and also offers improved suppression of reference sideband spurs.

The counters are programmed via a synchronous serial port which is SPI compatible. The serial port is byte-oriented to facilitate control via an MCU. Due to the innovative BitGrabber Plus™ registers, the MC145202-1 may be cascaded with other peripherals featuring BitGrabber Plus without requiring leading dummy bits or address bits in the serial data stream. In addition, BitGrabber Plus peripherals may be cascaded with existing BitGrabber™ peripherals.

The device features a single-ended current source/sink phase detector A output and a double-ended phase detector B output. Both phase detectors have linear transfer functions (no dead zones). The maximum current of the single-ended phase detector output is determined by an external resistor tied from the Rx pin to ground. This current can be varied via the serial port.

Slew-rate control is provided by a special driver designed for the REF<sub>Out</sub> pin. This minimizes interference caused by REF<sub>Out</sub>.

This part includes a differential RF input that may be operated in a single-ended mode. Also featured are on-board support of an external crystal and a programmable reference output. The R, A, and N counters are fully programmable. The C register (configuration register) allows the part to be configured to meet various applications. A patented feature allows the C register to shut off unused outputs, thereby minimizing system noise and interference.

In order to have consistent lock times and prevent erroneous data from being loaded into the counters, on-board circuitry synchronizes the update of the A register if the A or N counters are loading. Similarly, an update of the R register is synchronized if the R counter is loading.

The double-buffered R register allows new divide ratios to be presented to the three counters (R, A, and N) simultaneously.

- Maximum Operating Frequency: 2000 MHz @ -10 dBm
- Operating Supply Current: 4 mA Nominal at 3.0 V
- Operating Supply Voltage Range (V<sub>DD</sub>, V<sub>CC</sub>, V<sub>PD</sub> Pins): 2.7 to 5.5 V
- Current Source/Sink Phase Detector Output:  
1.7 mA @ 5.0 V or 1.0 mA @ 3.0 V
- Gain of Current Source/Sink Phase/Frequency Detector Controllable via Serial Port
- R Counter Division Range: 1 and 5 to 8191
- Dual-Modulus Capability Provides Total Division up to 262,143
- High-Speed Serial Interface: 4 Mbps
- Output A Pin, When Configured as Data Out, Permits Cascading of Devices
- Two General-Purpose Digital Outputs:  
Output A: Totem-Pole (Push-Pull) with Four Output Modes  
Output B: Open-Drain
- Patented Power-Saving Standby Feature with Orderly Recovery for Minimizing Lock Times, Standby Current: 30 μA
- See App Note AN1253/D for Low-Pass Filter Design, and AN1277/D for Offset Reference PLLs for Fine Resolution or Fast Hopping

 Pin 7 = Gnd (Common Ground)

**Table 1. Differences in the PLL Frequency Synthesizers**

Parameter	Preferred	Not Recommended For New Designs		
	MC145202-1	MC145202	MC145201	MC145200
Supply Voltage, V <sub>DD</sub> and V <sub>CC</sub> (main supply)	2.7 to 5.5 V	2.7 to 5.5 V	4.5 to 5.5 V	4.5 to 5.5 V
Supply Voltage, V <sub>PD</sub> (charge pump supply)	2.7 to 5.5 V	2.7 to 5.5 V	4.5 to 5.5 V	8.0 to 9.5 V
Supply Current	4 mA	4 mA	12 mA	12 mA
Value of External Resistor Rx, typical	3.9 kΩ for 1.7 mA [Note]	3.9 kΩ for 1.7 mA	18 kΩ for 2.0 mA	47 kΩ for 2.0 mA
Serial Programming with only 1 PLL (not cascaded)	Same, No Change	Same	Same	Same
Serial Programming with 2 or more PLLS (cascaded)	No leading dummy bits	No leading dummy bits	Leading dummy bits	Leading dummy bits

**NOTE:** Preliminary value.

## Dual 1.1 GHz PLL Frequency Synthesizer

### BiCMOS

The MC145220 is a low-voltage, single-chip frequency synthesizer with serial interface capable of direct usage up to 1.1 GHz. The device simultaneously supports two loops. The two on-chip dual-modulus prescalers may be independently programmed to divide by either 32/33 or 64/65.

The device consists of two dual-modulus prescalers, two 6-stage A counters, two 12-stage N counters, two fully programmable 13-stage R (reference) counters, and two lock detectors. Four phase/frequency detectors are included: two with current source/sink outputs and two with double-ended outputs.

The counters are programmed via a synchronous serial port which is SPI compatible. The serial port is byte-oriented to facilitate control via an MCU. Due to the innovative BitGrabber Plus™ registers, the MC145220 may be cascaded with other peripherals featuring BitGrabber Plus without requiring leading dummy bits or multiple address bits in the serial data stream. In addition, BitGrabber Plus peripherals may be cascaded with existing BitGrabber™ peripherals. Because this device is a dual synthesizer, a single steering bit is used in the serial data stream to direct the data to either side of the chip.

The phase/frequency detectors have linear transfer functions (no dead zones). The current delivered by the current source/sink outputs is controllable via the serial port.

Also featured are low-power standby for either one or both loops and on-board support of an external crystal. In addition, the part may be configured such that the REF<sub>IN</sub> pin accepts an external reference signal. In this configuration, the REF<sub>OUT</sub> pin may be programmed to output the REF<sub>IN</sub> frequency divided by 1, 2, 4, 8, or 16.

- Operating Frequency: 40 to 1100 MHz
- Operating Supply Voltage Range: 2.7 to 5.5 V
- Supply Current: Both PLLs Operating — 12 mA Nominal  
One PLL Operating, One on Standby — 6.5 mA Nominal  
Both PLLs on Standby — 30 μA Maximum
- Phase Detector Output Current: Up to 2 mA @ 5 V  
Up to 1 mA @ 3 V
- Operating Temperature Range: – 40 to 85°C
- Independent R Counters Allow Use of Different Step Sizes for Each Loop
- Double-Buffered R Register — Reference and Loop Divide Ratios Updated Simultaneously
- R Counter Division Range: 1 and 10 to 8,191
- Dual-Modulus Capability Provides Total Division of the VCO Frequency up to 262,143
- Direct Interface to Motorola SPI Data Port
- Evaluation Kit Available (Part Number MC145220EVK)
- See Application Note AN1253/D for Low-Pass Filter Design, and AN1277/D for Offset Reference PLLs for Fine Resolution or Fast Hopping

**MAXIMUM RATINGS\*** (Voltages Referenced to GND, unless otherwise stated)

Symbol	Parameter	Value	Unit
V+, V+'	DC Supply Voltage	- 0.5 to + 6.0	V
V <sub>in</sub>	DC Input Voltage	- 0.5 to V+ + 0.5	V
V <sub>out</sub>	DC Output Voltage	- 0.5 to V+ + 0.5	V
I <sub>in</sub>	DC Input Current, per Pin	± 10	mA
I <sub>out</sub>	DC Output Current, per Pin	± 20	mA
I	DC Supply Current, V+, V+', GND, and GND' Pins	30	mA
P <sub>D</sub>	Power Dissipation, per Package	300	mW
T <sub>stg</sub>	Storage Temperature	- 65 to + 150	°C
T <sub>L</sub>	Lead Temperature, 1 mm from Case for 10 Seconds	260	°C

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit.

\* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.

**ELECTRICAL CHARACTERISTICS**

(V+ = V+ ' = 2.7 to 5.5 V, GND = GND', Voltages Referenced to GND, T<sub>A</sub> = - 40 to 85°C, unless otherwise stated)

Symbol	Parameter	Test Condition	Guaranteed Limit	Unit
V <sub>IL</sub>	Maximum Low-Level Input Voltage (D <sub>in</sub> , CLK, $\overline{\text{ENB}}$ , REF <sub>in</sub> )	Device in Reference Mode, dc Coupled	0.3 x V+	V
V <sub>IH</sub>	Minimum High-Level Input Voltage (D <sub>in</sub> , CLK, $\overline{\text{ENB}}$ , REF <sub>in</sub> )	Device in Reference Mode, dc Coupled	0.7 x V+	V
V <sub>Hys</sub>	Minimum Hysteresis Voltage (CLK, $\overline{\text{ENB}}$ )		100	mV
V <sub>OL</sub>	Maximum Low-Level Output Voltage (LD, LD', REF <sub>out</sub> , Output A)	I <sub>out</sub> = 20 μA, Device in Reference Mode; Output A Not Selected as Port	0.1	V
V <sub>OH</sub>	Minimum High-Level Output Voltage (REF <sub>out</sub> , Output A)	I <sub>out</sub> = - 20 μA, Device in Reference Mode; Output A Not Selected as Port	V+ - 0.1	V
I <sub>OL</sub>	Minimum Low-Level Output Current (REF <sub>out</sub> )	V <sub>out</sub> = 0.3 V	0.5	mA
I <sub>OL</sub>	Minimum Low-Level Output Current (PD <sub>out</sub> /φ <sub>R</sub> , PD <sub>out</sub> '/φ <sub>R</sub> ', Rx/φ <sub>V</sub> , Rx'/φ <sub>V</sub> ')	V <sub>out</sub> = 0.3 V; Phase/Frequency Detectors Configured with φ <sub>R</sub> , φ <sub>V</sub> Outputs	0.5	mA
I <sub>OL</sub>	Minimum Low-Level Output Current (Output A)	V <sub>out</sub> = 0.3 V	0.5	mA
I <sub>OL</sub>	Minimum Low-Level Output Current (LD, LD')	V <sub>out</sub> = 0.3 V	0.5	mA
I <sub>OH</sub>	Minimum High-Level Output Current (REF <sub>out</sub> )	V <sub>out</sub> = V+ - 0.3 V	- 0.4	mA
I <sub>OH</sub>	Minimum High-Level Output Current (PD <sub>out</sub> /φ <sub>R</sub> , PD <sub>out</sub> '/φ <sub>R</sub> ', Rx/φ <sub>V</sub> , Rx'/φ <sub>V</sub> ')	V <sub>out</sub> = V+ - 0.3 V; Phase/Frequency Detectors Configured with φ <sub>R</sub> , φ <sub>V</sub> Outputs	- 0.4	mA
I <sub>OH</sub>	Minimum High-Level Output Current (Output A)	V <sub>out</sub> = V+ - 0.3 V; Output A Not Selected as Port	- 0.4	mA
I <sub>in</sub>	Maximum Input Leakage Current (D <sub>in</sub> , CLK, $\overline{\text{ENB}}$ , REF <sub>in</sub> )	V <sub>in</sub> = V+ or GND; Device in XTAL Mode	± 1.0	μA
I <sub>in</sub>	Maximum Input Current (REF <sub>in</sub> )	V <sub>in</sub> = V+ or GND; Device in Reference Mode	± 150	μA
I <sub>OZ</sub>	Maximum Output Leakage Current (PD <sub>out</sub> /φ <sub>R</sub> , PD <sub>out</sub> '/φ <sub>R</sub> ')	V <sub>out</sub> = V+ or GND; Phase/Frequency Detectors Configured with PD <sub>out</sub> Output, Output in High-Impedance State	± 150	nA
I <sub>OZ</sub>	Maximum Output Leakage Current (Output A, LD, LD')	V <sub>out</sub> = V+ or GND; Output A Selected as Port; Output in High-Impedance State	± 5	μA
I <sub>STBY</sub>	Maximum Standby Supply Current	V <sub>in</sub> = V+ or GND; Outputs Open; Both PLLs in Standby Mode, Shut-Down Crystal Mode or REF <sub>out</sub> -Static-Low Reference Mode	30	μA
I <sub>T</sub>	Total Operating Supply Current	f <sub>in</sub> = f <sub>in</sub> ' = 1.1 GHz; both loops active; REF <sub>in</sub> = 13 MHz @ 1 V p-p; Output A = Inactive; All Outputs = No Connect; D <sub>in</sub> , ENB, CLK = V+ or GND; Phase/Frequency Detectors Configured with φ <sub>R</sub> , φ <sub>V</sub> Outputs	*	mA

\* The nominal value is 12 mA. This is not a guaranteed limit.

## ANALOG CHARACTERISTICS — CURRENT SOURCE/SINK OUTPUTS — PD<sub>out</sub>/φ<sub>R</sub> AND PD<sub>out</sub>/φ<sub>R</sub>'

(Phase/Frequency Detectors Configured with PD<sub>out</sub> Outputs, I<sub>out</sub> ≤ 2 mA @ V<sub>+</sub> = V<sub>+</sub>' = 4.5 to 5.5 V, I<sub>out</sub> ≤ 1 mA @ V<sub>+</sub> = V<sub>+</sub>' = 2.7 to 4.4 V, GND = GND', Voltages Referenced to GND)

Parameter	Test Condition	Guaranteed Limit	Unit
Maximum Source Current Variation Part-to-Part (Notes 3 and 4)	V <sub>out</sub> = 0.5 x V <sub>+</sub>	± 20	%
Maximum Sink-versus-Source Mismatch (Note 3)	V <sub>out</sub> = 0.5 x V <sub>+</sub>	12	%
Output Voltage Range (Note 3)	I <sub>out</sub> variation ≤ 20%	0.5 to V <sub>+</sub> – 0.5 V	V

### NOTES:

- Percentages calculated using the following formula: (Maximum Value – Minimum Value)/Maximum Value.
- See Rx Pin Description for external resistor values.
- This parameter is guaranteed for a given temperature within – 40 to 85°C and given supply voltage within 2.7 to 5.5 V.
- Applicable for the Rx/φ<sub>V</sub> or Rx'/φ<sub>V</sub>' reference pin tied to the GND or GND' pin through a resistor. See Pin Descriptions for suggested resistor values.

## AC INTERFACE CHARACTERISTICS

(V<sub>+</sub> = V<sub>+</sub>' = 2.7 to 5.5 V, GND = GND', T<sub>A</sub> = – 40 to 85°C, C<sub>L</sub> = 25 pF, Input t<sub>r</sub> = t<sub>f</sub> = 10 ns)

Symbol	Parameter	Guaranteed Limit	Unit
f <sub>clk</sub>	Serial Data CLK Frequency (Figure 1) NOTE: Refer to Clock t <sub>w</sub> below	dc to 2.0	MHz
t <sub>PLH</sub> , t <sub>PHL</sub>	Maximum Propagation Delay, CLK to Output A (Selected as Data Out) (Figures 1 and 5)	200	ns
t <sub>PZL</sub> , t <sub>PLZ</sub>	Maximum Propagation Delay, $\overline{\text{ENB}}$ to Output A (Selected as Port) (Figures 2 and 6)	200	ns
t <sub>TLH</sub> , t <sub>THL</sub>	Maximum Output Transition Time, Output A; t <sub>THL</sub> only, on Output A when Selected as Port (Figures 1, 5, and 6)	200	ns
C <sub>in</sub>	Maximum Input Capacitance — D <sub>in</sub> , CLK, $\overline{\text{ENB}}$	10	pF

## TIMING REQUIREMENTS (V<sub>+</sub> = V<sub>+</sub>' = 2.7 to 5.5 V, GND = GND', T<sub>A</sub> = – 40 to 85°C, Input t<sub>r</sub> = t<sub>f</sub> = 10 ns unless otherwise indicated)

Symbol	Parameter	Guaranteed Limit	Unit
t <sub>su</sub> , t <sub>h</sub>	Minimum Setup and Hold Times, D <sub>in</sub> versus CLK (Figure 3)	50	ns
t <sub>su</sub> , t <sub>h</sub> , t <sub>rec</sub>	Minimum Setup, Hold, and Recovery Times, $\overline{\text{ENB}}$ versus CLK (Figure 4)	100	ns
t <sub>w</sub>	Minimum Pulse Width, $\overline{\text{ENB}}$ (Figure 4)	*	cycles
t <sub>w</sub>	Minimum Pulse Width, CLK (Figure 1)	250	ns
t <sub>r</sub> , t <sub>f</sub>	Maximum Input Rise and Fall Times — CLK (Figure 1)	100	μs

\* The minimum limit is 3 REF<sub>in</sub> cycles or 195 f<sub>in</sub> or f<sub>in</sub>' cycles with selection of a 64/65 prescale ratio or 99 f<sub>in</sub> or f<sub>in</sub>' cycles with selection of a 32/33 prescale ratio, whichever is greater.

## PIN DESCRIPTIONS

### DIGITAL INTERFACE PINS

#### D<sub>in</sub>

#### Serial Data Input (Pin 20)

The bit stream begins with the MSB and is shifted in on the low-to-high transition of CLK. The bit pattern is 1 byte (8 bits) long to access the C or configuration registers, 2 bytes (16 bits) to access the first buffer of the R registers, or 3 bytes (24 bits) to access the A registers (see Table 1). The values in the registers do not change during shifting because the transfer of data to the registers is controlled by  $\overline{\text{ENB}}$ .

#### NOTE

The value programmed for the N counter must be greater than or equal to the value of the A counter.

The 13 LSBs of the R registers are double-buffered. As indicated above, data is latched into the first buffer on a 16-bit transfer. (The 3 MSBs are not double-buffered and have an immediate effect after a 16-bit transfer.) The two second buffers of the R register contain the two 13-bit divide ratios for the R counters. These second buffers are loaded with the contents of the first buffer as follows. Whenever the A register is loaded, the Rs (second) buffer is loaded from the R (first) buffer. Similarly, whenever the A' register is loaded, the Rs' (second) buffer is updated from the R (first) buffer. This allows presenting new values to the R, A, and N counters simultaneously. Note that two different R counter divide ratios may be established: one for the main PLL and another for PLL'.

The bit stream does not need address bits due to the innovative BitGrabber Plus registers. A steering bit is used to direct data to either the main PLL or PLL' section of the chip. Data is retained in the registers over a supply range of 2.7 to 5.5 V. The formats are shown in Figures 14, 15, and 16.

D<sub>in</sub> typically switches near 50% of V<sub>+</sub> to maximize noise immunity. This input can be directly interfaced to CMOS devices with outputs guaranteed to switch near rail-to-rail. When interfacing to NMOS or TTL devices, either a level shifter (MC74HC14A, MC14504B) or pull-up resistor of 1 kΩ to 10 kΩ must be used. Parameters to consider when sizing the resistor are worst-case I<sub>OL</sub> of the driving device, maximum tolerable power consumption, and maximum data rate.

**Table 1. Register Access**

(MSBs are shifted in first; C0, R0, and A0 are the LSBs)

Number of Clocks	Accessed Register	Bit Nomenclature
8	C Registers	C7, C6, C5, . . . , C0
16	R Register, First Buffer	R15, R14, R13, . . . , R0
24	A Registers	A23, A22, A21, . . . , A0
Other Values ≤ 32 Values > 32	Not Allowed See Figures 24 to 27	

#### CLK

#### Serial Data Clock Input (Pin 19)

Low-to-high transitions on CLK shift bits available at the D<sub>in</sub> pin, while high-to-low transitions shift bits from Output A (when configured as Data Out, see Pin 10). The 24-1/2 stage shift register is static, allowing clock rates down to dc in a continuous or intermittent mode.

Eight clock cycles are required to access the C registers. Sixteen clock cycles are needed for the first buffer of the R register. Twenty-four cycles are used to access the A registers. See Table 1 and Figures 14, 15, and 16. The number of clocks required for cascaded devices is shown in Figures 25 through 27.

CLK typically switches near 50% of V<sub>+</sub> and has a Schmitt-triggered input buffer. Slow CLK rise and fall times are allowed. See the last paragraph of D<sub>in</sub> for more information.

#### NOTE

To guarantee proper operation of the power-on reset (POR) circuit, the CLK pin must be held at GND (with  $\overline{\text{ENB}}$  being a don't care) or  $\overline{\text{ENB}}$  must be held at the potential of the V<sub>+</sub> pin (with CLK being a don't care) during power-up. Floating, toggling, or having these pins in the wrong state during power-up does not harm the chip, but causes two potentially undesirable effects. First, the outputs of the device power up in an unknown state. Second, if two devices are cascaded, the A Registers must be written twice after power up. After these two accesses, the two cascaded chips perform normally.

#### $\overline{\text{ENB}}$

#### Active-Low Enable Input (Pin 11)

This pin is used to activate the serial interface to allow the transfer of data to/from the device. When  $\overline{\text{ENB}}$  is in an inactive high state, shifting is inhibited and the port is held in the initialized state. To transfer data to the device,  $\overline{\text{ENB}}$  (which must start inactive high) is taken low, a serial transfer is made via D<sub>in</sub> and CLK, and  $\overline{\text{ENB}}$  is taken back high. The low-to-high transition on  $\overline{\text{ENB}}$  transfers data to the C or A registers and first buffer of the R register, depending on the data stream length per Table 1.

#### NOTE

Transitions on  $\overline{\text{ENB}}$  must not be attempted while CLK is high. This puts the device out of synchronization with the microcontroller. Resynchronization occurs whenever  $\overline{\text{ENB}}$  is high and CLK is low.

This input is Schmitt-triggered and switches near 50% of V<sub>+</sub>, thereby minimizing the chance of loading erroneous data into the registers. See the last paragraph of D<sub>in</sub> for more information.

For POR information, see the note for the CLK pin.

## OUTPUT A Configurable Digital Output (Pin 10)

Output A is selectable as  $f_R$ ,  $f_V$ ,  $f_{R'}$ ,  $f_{V'}$ , Data Out, or Port. Bits A21 and A22 and the steering bit (A23) control the selection; see Figure 15. When selected as Port, the pin becomes an open-drain N-channel MOSFET output. As such, a pullup device is needed for pin 10. With all other selections, the pin is a totem-pole (push-pull) output.

If A22 = A21 = high, Output A is configured as  $f_R$  when the steering bit is low and  $f_{R'}$  when the bit is high. These signals are the buffered outputs of the 13-stage R counters. The signals appear as normally low and pulse high. The signals can be used to verify the divide ratios of the R counters. These ratios extend from 10 to 8191 and are determined by the binary value loaded into bits R0 – R12 in the R register. Also, direct access to the phase detectors via the  $REF_{IN}$  pin is allowed by choosing a divide value of one. See Figure 16. The maximum frequency at which the phase detectors operate is 1 MHz. Therefore, the frequency of  $f_R$  and  $f_{R'}$  should not exceed 1 MHz.

If A22 = high and A21 = low, Output A is configured as  $f_V$  when the steering bit is low and  $f_{V'}$  when the bit is high. These signals are the buffered outputs of the 12-stage N counters. The signals appear as normally low and pulse high. The signals can be used to verify the operation of the prescalers, A counters, and N counters. The divide ratio between the  $f_{IN}$  or  $f_{IN'}$  input and the  $f_V$  or  $f_{V'}$  signal is  $N \times P + A$ . N is the divide ratio of the N counter, P is 32 with a 32/33 prescale ratio or 64 with a 64/65 prescale ratio, and A is the divide ratio of the A counter. These ratios are determined by bits loaded into the A registers. See Figure 15. The maximum frequency at which the phase detectors operate is 1 MHz. Therefore, the frequency of  $f_V$  and  $f_{V'}$  should not exceed 1 MHz.

If A22 = low and A21 = high, Output A is configured as Data Out. This signal is the serial output of the 24-1/2 stage shift register. The bit stream is shifted out on the high-to-low transition of the CLK input. Upon power up, Output A is automatically configured as Data Out to facilitate cascading devices.

If A22 = A21 = low, Output A is configured as Port. This signal is a general-purpose digital output which may be used as an MCU port expander. This signal is low when the Port bit (C1) of the C register is low, and high impedance when the Port bit is high. See Figure 14.

## REFERENCE PINS

### $REF_{IN}$ and $REF_{OUT}$ Reference Oscillator Input and Output (Pins 1 and 2)

Configurable Pins for a Crystal or an External Reference. This pair of pins can be configured in one of two modes: the crystal mode or the reference mode. Bits R13, R14, and R15 in the R register control the modes as shown in Figure 16.

In the crystal mode, these pins form a reference oscillator when connected to terminals of an external parallel-resonant crystal. Frequency-setting capacitors of appropriate

values, as recommended by the crystal supplier, are connected from each of the two pins to ground (up to a maximum of 30 pF each, including stray capacitance). An external resistor of 1 M $\Omega$  to 15 M $\Omega$  is connected directly across the pins to ensure linear operation of the amplifier. The required connections for the crystal are shown in Figure 9. To turn on the oscillator, bits R15, R14, and R13 must have an octal value of one (001 in binary). This is the active-crystal mode shown in Figure 16. In this mode, the crystal oscillator runs and the R Counter divides the crystal frequency, unless the part is in standby. If the part is placed in standby via the C or C' register, the oscillator runs, but the R or R' counter is stopped, respectively. However, if bits R15 to R13 have a value of 0, the oscillator is stopped, which saves additional power. This is the shut-down crystal mode shown in Figure 16, and can be engaged whether in standby or not.

In the reference mode,  $REF_{IN}$  (pin 1) accepts a signal from an external reference oscillator, such as a TCXO. A signal swinging from at least the  $V_{IL}$  to  $V_{IH}$  levels listed in the **Electrical Characteristics** table may be directly coupled to the pin. If the signal is less than this level, ac coupling must be used as shown in Figure 8. The ac-coupled signal must be at least 400 mV p-p. Due to an on-board resistor which is engaged in the reference modes, an external biasing resistor tied between  $REF_{IN}$  and  $REF_{OUT}$  is not required.

With the reference mode, the  $REF_{OUT}$  pin is configured as the output of a divider. As an example, if bits R15, R14, and R13 have an octal value of seven, the frequency at  $REF_{OUT}$  is the  $REF_{IN}$  frequency divided by 16. In addition, Figure 16 shows how to obtain ratios of eight, four, and two. A ratio of one-to-one can be obtained with an octal value of three. Upon power up, a ratio of eight is automatically initialized. The maximum frequency capability of the  $REF_{OUT}$  pin is 5 MHz for large output swings ( $V_{OH}$  to  $V_{OL}$ ) and 25 pF loads. Therefore, for  $REF_{IN}$  frequencies above 5 MHz, the one-to-one ratio may not be used for these large signal swing and large  $C_L$  requirements. Likewise, for  $REF_{IN}$  frequencies above 10 MHz, the ratio must be more than two.

If  $REF_{OUT}$  is unused, an octal value of two should be used for R15, R14, and R13 and the  $REF_{OUT}$  pin should be floated. A value of two allows  $REF_{IN}$  to be functional while disabling  $REF_{OUT}$ , which minimizes dynamic power consumption and electromagnetic interference (EMI).

## LOOP PINS

### $f_{IN}$ , $\overline{f_{IN}}$ and $f_{IN'}$ , $\overline{f_{IN'}}$ Frequency Inputs (Pins 8, 7 and 13, 14)

These pins feed the onboard RF amplifiers which drive the prescalers. These inputs may be fed differentially. However, they usually are used in single-ended configurations (shown in Figure 7). Note that  $f_{IN}$  is driven while  $\overline{f_{IN}}$  must be tied to ac ground (via capacitor). The signal sources driving these pins originate from external VCOs.

Motorola does not recommend driving  $\overline{f_{IN}}$  while terminating  $f_{IN}$  because this configuration is not tested for sensitivity. The sensitivity is dependent on the frequency as shown in the **Loop Specifications** table.

**PD<sub>out</sub>/φ<sub>R</sub>, PD<sub>out</sub>'/φ<sub>R</sub>'  
Single-Ended Phase/Frequency Detector Outputs  
(Pins 4 and 17)**

When the C2 bits in the C or C' registers are low, these pins are independently configured as single-ended outputs PD<sub>out</sub> or PD<sub>out</sub>', respectively. As such, each pin is a three-state current-source/sink output for use as a loop error signal when combined with an external low-pass filter. The phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detector is described below and is shown in Figure 17.

POL bit (C0) in the C register = low (see Figure 14)

Frequency of f<sub>V</sub> > f<sub>R</sub> or Phase of f<sub>V</sub> Leading f<sub>R</sub>: current-sinking pulses from a floating state

Frequency of f<sub>V</sub> < f<sub>R</sub> or Phase of f<sub>V</sub> Lagging f<sub>R</sub>: current-sourcing pulses from a floating state

Frequency and Phase of f<sub>V</sub> = f<sub>R</sub>: essentially a floating state; voltage at pin determined by loop filter

POL bit (C0) = high

Frequency of f<sub>V</sub> > f<sub>R</sub> or Phase of f<sub>V</sub> Leading f<sub>R</sub>: current-sourcing pulses from a floating state

Frequency of f<sub>V</sub> < f<sub>R</sub> or Phase of f<sub>V</sub> Lagging f<sub>R</sub>: current-sinking pulses from a floating state

Frequency and Phase of f<sub>V</sub> = f<sub>R</sub>: essentially a floating state; voltage at pin determined by loop filter

These outputs can be enabled, disabled, and inverted via the C and C' registers. If desired, these pins can be forced to the floating state by utilization of the standby feature in the C or C' registers (bit C6). This is a patented feature.

The phase detector gain is controllable by bits C4 and C5: gain (in amps per radian) = PD<sub>out</sub> current in amps divided by 2π.

**PD<sub>out</sub>/φ<sub>R</sub>, Rx/φ<sub>V</sub> and PD<sub>out</sub>'/φ<sub>R</sub>', Rx'/φ<sub>V</sub>'  
Double-Ended Phase/Frequency Detector Outputs  
(Pins 4, 5 and 17, 16)**

When the C2 bits in the C or C' registers are high, these two pairs of pins are independently configured as double-ended outputs φ<sub>R</sub>, φ<sub>V</sub> or φ<sub>R</sub>', φ<sub>V</sub>', respectively. As such, these outputs can be combined externally to generate a loop error signal. Through use of a Motorola patented technique, the detector's dead zone has been eliminated. Therefore, the phase/frequency detector is characterized by a linear transfer function. The operation of the phase/frequency detectors are described below and are shown in Figure 17.

POL bit (C0) in the C register = low (see Figure 14)

Frequency of f<sub>V</sub> > f<sub>R</sub> or Phase of f<sub>V</sub> Leading f<sub>R</sub>: φ<sub>V</sub> = negative pulses, φ<sub>R</sub> = essentially high

Frequency of f<sub>V</sub> < f<sub>R</sub> or Phase of f<sub>V</sub> Lagging f<sub>R</sub>: φ<sub>V</sub> = essentially high, φ<sub>R</sub> = negative pulses

Frequency and Phase of f<sub>V</sub> = f<sub>R</sub>: φ<sub>V</sub> and φ<sub>R</sub> remain essentially high, except for a small minimum time period when both pulse low in phase

POL bit (C0) = high

Frequency of f<sub>V</sub> > f<sub>R</sub> or Phase of f<sub>V</sub> Leading f<sub>R</sub>: φ<sub>R</sub> = negative pulses, φ<sub>V</sub> = essentially high

Frequency of f<sub>V</sub> < f<sub>R</sub> or Phase of f<sub>V</sub> Lagging f<sub>R</sub>: φ<sub>R</sub> = essentially high, φ<sub>V</sub> = negative pulses

Frequency and Phase of f<sub>V</sub> = f<sub>R</sub>: φ<sub>V</sub> and φ<sub>R</sub> remain essentially high, except for a small minimum time period when both pulse low in phase

These outputs can be enabled, disabled, or interchanged via C register bits C6 or C0. This is a patented feature. Note that when disabled in standby, these outputs are forced to their rest condition (high state). See Figure 14.

The φ<sub>R</sub> and φ<sub>V</sub> output signals swing from approximately GND to V+.

**LD and LD'  
Lock Detector Outputs (Pins 3 and 18)**

Each output is essentially at a high-impedance state with very narrow low-going pulses of a few nanoseconds when the respective loop is locked (f<sub>R</sub> and f<sub>V</sub> of the same phase and frequency). The output pulses low when f<sub>V</sub> and f<sub>R</sub> are out of phase or different frequencies. LD is the logical ANDing of φ<sub>R</sub> and φ<sub>V</sub>, while LD' is the logical ANDing of φ<sub>R</sub>' and φ<sub>V</sub>'. See Figure 17.

Upon power up, on-chip initialization circuitry forces LD and LD' to the high-impedance state. These pins are low during standby. If unused, LD should be tied to GND and LD' should be tied to GND'.

These outputs have open-drain N-channel MOSFET drivers. This facilitates a wired-OR function. See Figure 21.

**Rx/φ<sub>V</sub> and Rx'/φ<sub>V</sub>'  
External Current Setting Resistors (Pins 5 and 16)**

When the C2 bits in the C or C' registers are low, these two pins are independently configured as current setting pins Rx or Rx', respectively. As such, resistors tied between each of these pins and GND and GND', in conjunction with bits C4 and C5 in the C and C' registers, determine the amount of current that the PD<sub>out</sub> pins sink and source. When bits C4 and C5 are both set high, the maximum current is obtained; see Table 2 for other values of current.

**Table 2. PD<sub>out</sub> or PD<sub>out</sub>' Current**

C5	C4	Current
0	0	5%
0	1	50%
1	0	80%
1	1	100%

The formula for determining the value of Rx or Rx' is as follows.

$$R_x = \frac{V1 - V2}{I}$$

where Rx is the value of external resistor in ohms, V1 is the supply voltage, V2 is 1.5 V for a reference current through Rx of 100 μA or 1.745 V for a reference current of 200 μA, and I is the reference current flowing through Rx or Rx'.

The reference current flowing through Rx or Rx' is multiplied by a factor of approximately 10 (in the 100% current mode) and delivered by the PD<sub>out</sub> or PD<sub>out</sub>' pin, respectively. To achieve a maximum phase detector output current of 1 mA, the resistor should be about 15 kΩ when a 3 V supply is employed. See Table 3.

**Table 3. Rx Values**

Supply Voltage	Rx	PD <sub>out</sub> or PD <sub>out</sub> ' Current in 100% Mode
3 V	15 kΩ	1 mA
5 V	16 kΩ	2 mA

Do not use a decoupling capacitor on the Rx or Rx' pin. Use of a capacitor causes undesirable current spikes to appear on the phase detector output when invoking the standby mode.

## **POWER SUPPLY PINS**

### **V+ and V+'**

#### **Positive Supply Potentials (Pins 9 and 12)**

V+ supplies power to the main PLL, reference circuit, and a portion of the serial port. V+' supplies power to PLL' and a portion of the serial port. Both V+ and V+' must be at the same voltage level and may range from 2.7 V to 5.5 V with respect to the GND and GND' pins.

For optimum performance, V+ should be bypassed to GND and V+' bypassed to GND' using separate low-inductance capacitors mounted very close to the MC145220. Lead lengths and printed circuit board traces to the capacitors should be minimized. (The very fast switching speed of the device can cause excessive current spikes on the power leads if they are improperly bypassed.)

### **GND and GND'**

#### **Grounds (Pins 6 and 15)**

The GND pin is the ground for the main PLL and GND' is the ground for PLL'.

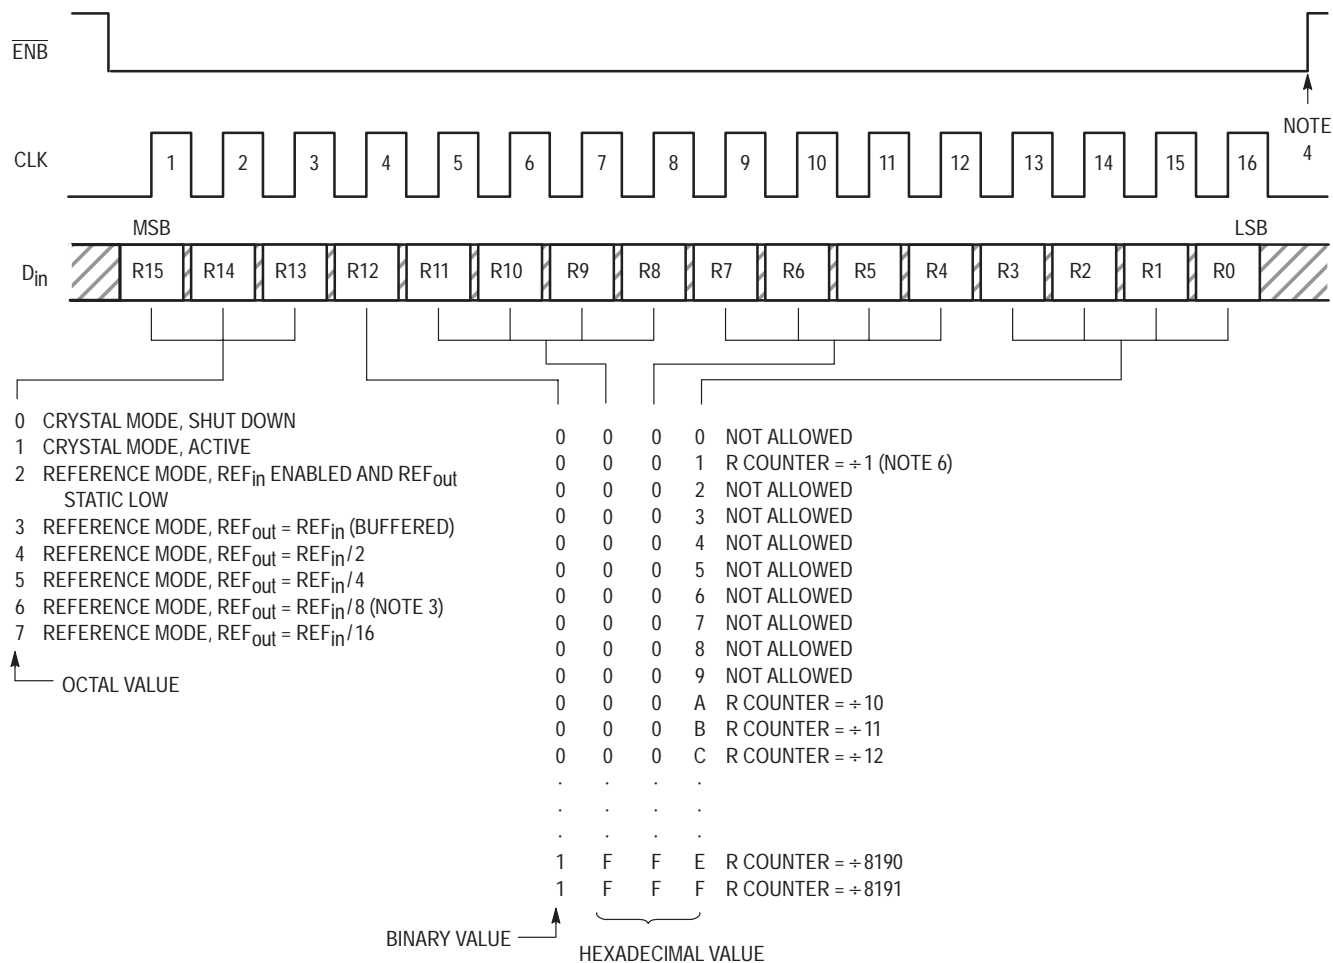

\* At this point, the new byte is transferred to the C or C' register and stored. No other registers are affected.

- C7 – Steer: Used to direct the data to either the C or C' register. A low level directs data to the C register; a high level is for the C' register.
- C6 – Standby: When set high, places both the main PLL and PLL' (when C6 is set in the C register) or PLL' only (when C6 is set in the C' register) in the standby mode for reduced power consumption. The associated PD<sub>OUT</sub> is forced to the floating state, the associated counters (A, N, and R) are inhibited from counting, the associated Rx current is shut off, and the associated prescaler stops counting and is placed in a low current mode. The associated double-ended phase/frequency detector outputs are forced to a high level. In standby, the associated LD output is placed in the low-state, thus indicating “not locked” (open loop). During standby, data is retained in all registers and any register may be accessed.
- In standby, the condition of the REF/OSC circuitry is determined by bits R13, R14, and R15 in the R register per Figure 16. However, if REF<sub>OUT</sub> = *static low* is selected, the internal feedback resistor is disconnected and the REF<sub>IN</sub> is inhibited when both PLL and PLL' are placed in standby via the C register. Thus, the REF<sub>IN</sub> only presents a capacitive load. **Note:** PLL/PLL' standby does not affect the other modes of the REF/OSC circuitry as determined by bits R13, R14, and R15 in the R register. The PLL' standby mode (controlled from the C' register) has no effect on the REF/OSC circuit.
- When C6 is reset low, the associated PLL (or PLLs) is (are) taken out of standby in two steps. First, the REF<sub>IN</sub> (only in 1 mode, PLL/PLL' in standby) resistor is reconnected, REF<sub>IN</sub> (only 1 mode) is gated on, all counters are enabled, and the Rx current is enabled. Any f<sub>R</sub> and f<sub>V</sub> signals are inhibited from toggling the phase/frequency detectors and lock detectors. Second, when the appropriate f<sub>R</sub> pulse occurs, the A and N counters are jam loaded, the prescaler is gated on, and the phase/frequency and lock detectors are initialized. Immediately after the jam load, the A, N, and R counters begin counting down together. At this point, the f<sub>R</sub> and f<sub>V</sub> pulses are enabled to the phase and lock detectors. (Patented feature.)
- C5, C4 – I2, I1: Independently controls the PD<sub>OUT</sub> or PD<sub>OUT</sub>' source/sink current per Table 2. With both bits high, the maximum current (as set by Rx or Rx') is available. POR forces C5 and C4 to high levels.
- C3 – Spare: Unused
- C2 – PDA/B: Independently selects which phase/frequency detector is to be used. When set high, the double-ended detector is selected with outputs φ<sub>R</sub> and φ<sub>V</sub> or φ<sub>R</sub>' and φ<sub>V</sub>'. When reset low, the current source/sink detector is selected with outputs PD<sub>OUT</sub> or PD<sub>OUT</sub>'. In the second case, the appropriate Rx or Rx' pin is tied to an external resistor. POR forces C2 low.
- C1 – Port: When the Output A pin is selected as “Port” via bits A22 and A21, C1 of the C register determines the state of Output A. When C1 is set high, Output A is forced to the high-impedance state; C1 low forces Output A low. The Port bit is not affected by the standby mode. **Note:** C1 of the C' register is not used in any mode.
- C0 – POL: Selects the output polarity of the associated phase/frequency detectors. When set high, this bit inverts the associated current source/sink output and interchanges the associated double-ended output relative to the waveforms in Figure 17. Also, see the phase detector output pin descriptions for more information. This bit is cleared low at power up.

**Figure 14. C and C' Register Accesses and Format (8 Clock Cycles are Used)**

NOTES:

1. Bits R15 – R13 control the configurable “Buffer and Control” block (see Block Diagram).
2. Bits R12 – R0 control the “13-stage R counter” blocks (see Block Diagram).
3. A power-on initialize circuit forces a default REF<sub>in</sub> to REF<sub>out</sub> ratio of eight.
4. At this point, bits R13, R14, and R15 are stored and sent to the “Buffer and Control” block in the Block Diagram. Bits R0 – R12 are loaded into the first buffer in the double-buffered section of the R register. Therefore, the R or R’ counter divide ratio is not altered yet and retains the previous ratio loaded. The C, C’, A, and A’ registers are not affected.
5. Bits R0 – R12 are transferred to the second buffer of the R register (Rs in the Block Diagram) on a subsequent 24-bit write to the A register. The bits are transferred to Rs’ on a subsequent 24-bit write to the A’ register. The respective R counter begins dividing by the new ratio after completing the rest of its present count cycle.
6. Allows direct access to reference input of phase/frequency detectors.

Figure 16. R Register Access and Format (16 Clock Cycles are Used)

NOTES:

1. At this point, when both  $f_R$  and  $f_V$  are in phase, the output source and sink circuits are turned on for a short interval.
2. The  $P_{Dout}$  either sources or sinks current during out-of-lock conditions. When locked in phase and frequency, the output is mostly in a floating condition and the voltage at that pin is determined by the low-pass filter capacitor.  $P_{Dout}$ ,  $\phi_R$ , and  $\phi_V$  are shown with the polarity bit (POL) = low; see Figure 14 for POL.
3.  $V_H$  = High voltage level,  $V_L$  = Low voltage level.
4. The waveforms are applicable to both the main PLL and PLL'.

Figure 17. Phase/Frequency Detectors and Lock Detector Output Waveforms

## DESIGN CONSIDERATIONS

### CRYSTAL OSCILLATOR CONSIDERATIONS

The following options may be considered to provide a reference frequency to Motorola's CMOS frequency synthesizers.

#### Use of a Hybrid Crystal Oscillator

Commercially available temperature-compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide very stable reference frequencies. An oscillator capable of CMOS logic levels at the output may be direct or dc coupled to REF<sub>in</sub>. If the oscillator does not have CMOS logic levels on the outputs, capacitive or ac coupling to REF<sub>in</sub> must be used. See Figure 8.

For additional information about TCXOs and data clock oscillators, please consult the latest version of the *eem Electronic Engineers Master Catalog*, the *Gold Book*, or similar publications.

#### Design an Off-Chip Reference

The user may design an off-chip crystal oscillator using discrete transistors or ICs specifically developed for crystal oscillator applications, such as the MC12061 MECL device. The reference signal from the MECL device is ac coupled to REF<sub>in</sub>. (See Figure 8.) For large amplitude signals (standard CMOS logic levels), dc coupling may be used.

#### Use of the On-Chip Oscillator Circuitry

The on-chip amplifier (a digital inverter) along with an appropriate crystal may be used to provide a reference source frequency. A fundamental mode crystal, parallel resonant at the desired operating frequency, should be connected as shown in Figure 18.

The crystal should be specified for a loading capacitance, C<sub>L</sub>, which does not exceed approximately 20 pF when used near the highest operating frequency of the MC145220. Assuming R1 = 0 Ω, the shunt load capacitance, C<sub>L</sub>, presented across the crystal can be estimated to be:

$$C_L = \frac{C_{in}C_{out}}{C_{in} + C_{out}} + C_a + C_{stray} + \frac{C1 \cdot C2}{C1 + C2}$$

where

$$C_{in} = 5 \text{ pF (see Figure 19)}$$

$$C_{out} = 6 \text{ pF (see Figure 19)}$$

$$C_a = 1 \text{ pF (see Figure 19)}$$

C1 and C2 = external capacitors (see Figure 18)

C<sub>stray</sub> = the total equivalent external circuit stray capacitance appearing across the crystal terminals

The oscillator can be "trimmed" on-frequency by making either a portion or all of C1 variable. The crystal and associated components must be located as close as possible to the REF<sub>in</sub> and REF<sub>out</sub> pins to minimize distortion, stray capacitance, stray inductance, and startup stabilization time. Circuit stray capacitance can also be handled by adding the appropriate stray value to the values for C<sub>in</sub> and C<sub>out</sub>. For this approach, the term C<sub>stray</sub> becomes zero in the above expression for C<sub>L</sub>.

Power is dissipated in the effective series resistance of the crystal, R<sub>e</sub>, in Figure 20. The maximum drive level specified by the crystal manufacturer represents the maximum stress that the crystal can withstand without damage or excessive shift in operating frequency. R1 in Figure 18 limits the drive level. The use of R1 is not necessary in most cases.

To verify that the maximum dc supply voltage does not cause the crystal to be overdriven, monitor the output frequency (f<sub>R</sub>) at Output A as a function of supply voltage. (REF<sub>out</sub> is not used because loading impacts the oscillator.) The frequency should increase very slightly as the dc supply voltage is increased. An overdriven crystal decreases in frequency or becomes unstable with an increase in supply voltage. The operating supply voltage must be reduced or R1 must be increased in value if the overdriven condition exists. Note that the oscillator start-up time is proportional to the value of R1.

Through the process of supplying crystals for use with CMOS inverters, many crystal manufacturers have developed expertise in CMOS oscillator design with crystals. Discussions with such manufacturers can prove very helpful. See Table 4.

\* May be needed in certain cases. See text.

## PHASE-LOCKED LOOP — LOW-PASS FILTER DESIGN

(A)

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC}}$$

$$\zeta = \frac{R}{2} \sqrt{\frac{K_\phi K_{VCO} C}{N}} = \frac{\omega_n RC}{2}$$

$$Z(s) = \frac{1 + sRC}{sC}$$

NOTE:

For (A), using  $K_\phi$  in amps per radian with the filter's impedance transfer function,  $Z(s)$ , maintains units of volts per radian for the detector/filter combination. Additional sideband filtering can be accomplished by adding a capacitor  $C'$  across  $R$ . The corner  $\omega_c = 1/RC'$  should be chosen such that  $\omega_n$  is not significantly affected.

(B)

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NCR_1}}$$

$$\zeta = \frac{\omega_n R_2 C}{2}$$

ASSUMING GAIN A IS VERY LARGE, THEN:

$$Z(s) = \frac{R_2 s C + 1}{R_1 s C}$$

NOTE:

For (B),  $R_1$  is frequently split into two series resistors; each resistor is equal to  $R_1$  divided by 2. A capacitor  $C_C$  is then placed from the midpoint to ground to further filter the error pulses. The value of  $C_C$  should be such that the corner frequency of this network does not significantly affect  $\omega_n$ .

DEFINITIONS:

$N$  = Total Division Ratio in Feedback Loop

$K_\phi$  (Phase Detector Gain) =  $I_{PDout}/2\pi$  amps per radian for  $PD_{out}$

$K_\phi$  (Phase Detector Gain) =  $V+/2\pi$  volts per radian for  $\phi_V$  and  $\phi_R$

$K_{VCO}$  (VCO Transfer Function) =  $\frac{2\pi\Delta f_{VCO}}{\Delta V_{VCO}}$  radians per volt

For a nominal design starting point, the user might consider a damping factor  $\zeta \approx 0.7$  and a natural loop frequency  $\omega_n \approx (2\pi f_R/50)$  where  $f_R$  is the frequency at the phase detector input. Larger  $\omega_n$  values result in faster loop lock times and, for similar sideband filtering, higher  $f_R$ -related VCO sidebands.

Either loop filter (A) or (B) is frequently followed by additional sideband filtering to further attenuate  $f_R$ -related VCO sidebands. This additional filtering may be active or passive.

NOTES:

1. The PD<sub>out</sub> output is fed to an external loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information.
2. For optimum performance, bypass the V+ and V+' pins to GND and GND' with low-inductance capacitors.
3. The R counter is programmed for a divide value = REF<sub>in</sub> / f<sub>R</sub>. Typically, f<sub>R</sub> is the tuning resolution required for the VCO. Also, the VCO frequency divided by f<sub>R</sub> = N<sub>T</sub> = N • P + A; this determines the values (N, A) that must be programmed into the N and A counters, respectively. P is the lower divide ratio of the dual-modulus prescaler (i.e., 32 or 64).
4. Pull-up voltage must be at the same potential as the V+ pin or less. Pull-up device other than a resistor may be used. (Pull-up device not required when Output A is configured as f<sub>R</sub>, f<sub>R'</sub>, f<sub>V</sub>, f<sub>V'</sub>, DATA OUT.)
5. LD and LD' are open-drain outputs. This allows the wired-OR configuration shown. Note that R1 and Q1 form the "pull-up device".
6. Use of Q1 is optional and depends on loading.

Figure 21. Application Showing Use of the Two Single-Ended Phase/Frequency Detectors

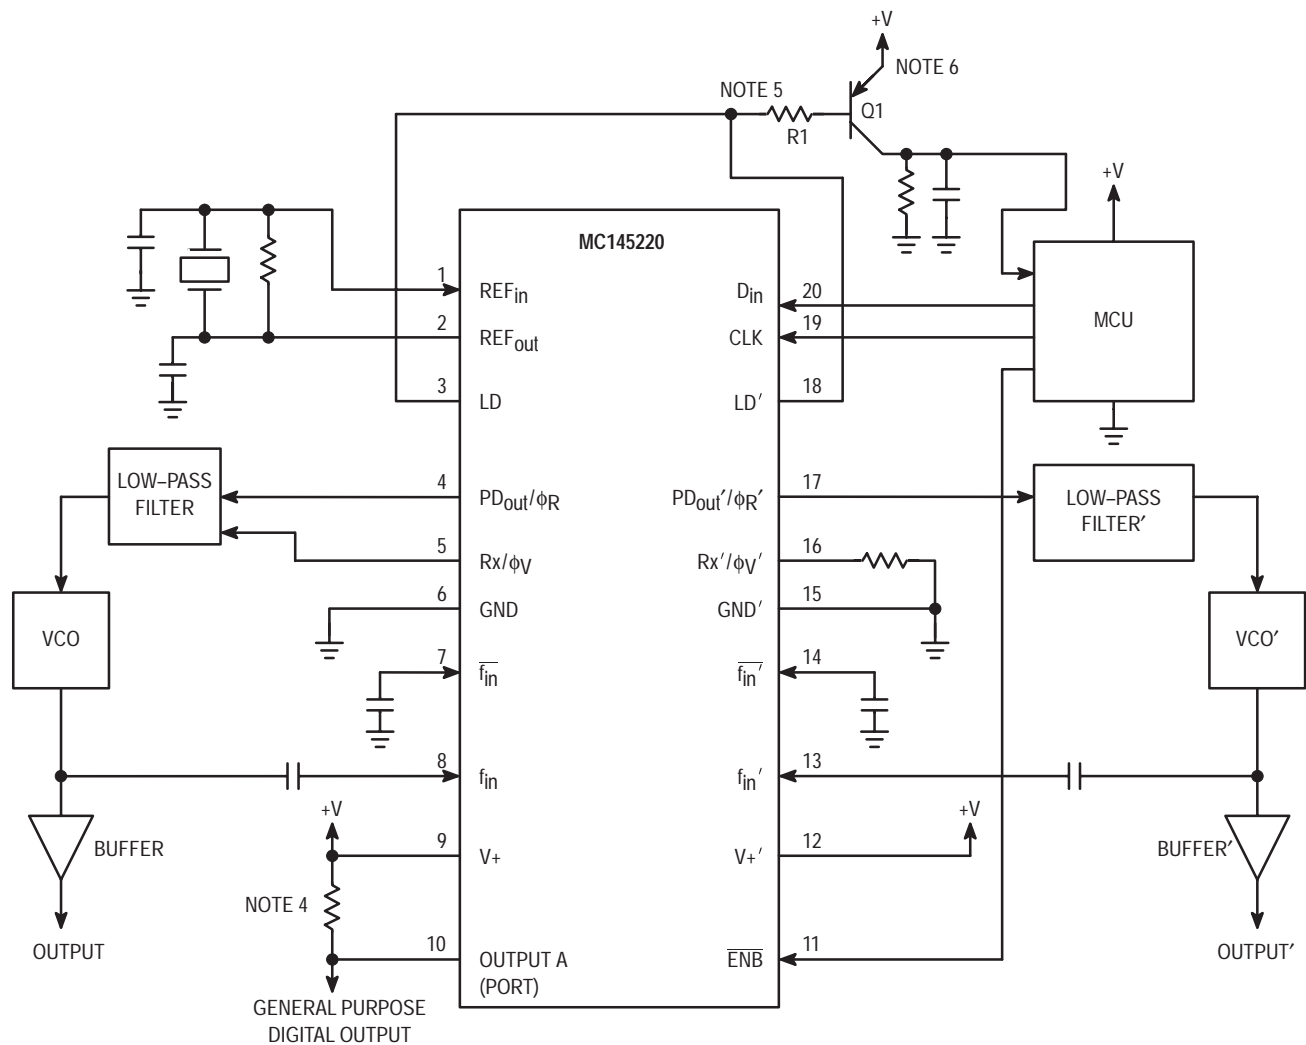

NOTES:

1. The  $\phi_R$  and  $\phi_V$  outputs are fed to an external combiner/loop filter. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information. The  $\phi_R$  and  $\phi_V$  outputs swing rail-to-rail. Therefore, the user should be careful not to exceed the common mode input range of the op amp used in the combiner/loop filter.
2. For optimum performance, bypass the  $V+$  and  $V+'$  pins to GND and GND' with low-inductance capacitors.
3. The R counter is programmed for a divide value =  $REF_{in} / f_R$ . Typically,  $f_R$  is the tuning resolution required for the VCO. Also, the VCO frequency divided by  $f_R = N_T = N \cdot P + A$ ; this determines the values (N, A) that must be programmed into the N and A counters, respectively. P is the lower divide ratio of the dual-modulus prescaler (i.e., 32 or 64).
4. Pull-up voltage must be at the same potential as the  $V+$  pin or less. Pull-up device other than a resistor may be used. (Pull-up device not required when Output A is configured as  $f_R$ ,  $f_R'$ ,  $f_V$ ,  $f_V'$ , DATA OUT.)
5. LD and LD' are open-drain outputs. This allows the wired-OR configuration shown. Note that R1 and Q1 form the "pull-up device".
6. Use of Q1 is optional and depends on loading.

Figure 22. Application Showing Use of the Two Double-Ended Phase/Frequency Detectors

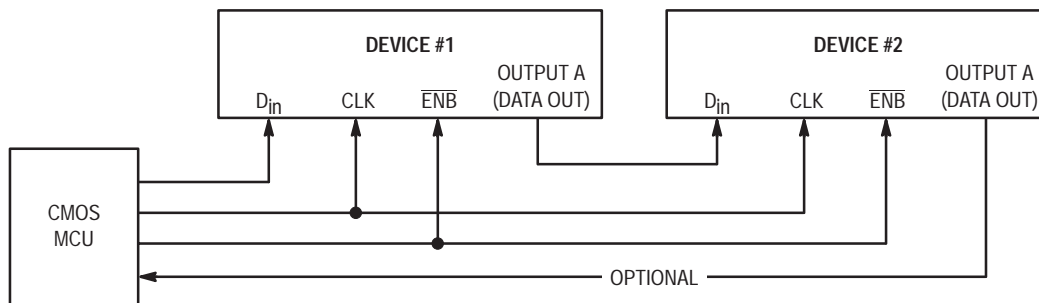

NOTES:

1. See the Phase-Locked Loop — Low-Pass Filter Design page for additional information.
2. For optimum performance, bypass the V+ and V+' pins to GND and GND' with low-inductance capacitors.
3. The R counter is programmed for a divide value =  $REF_{in} / f_R$ . Typically,  $f_R$  is the tuning resolution required for the VCO. Also, the VCO frequency divided by  $f_R = N_T = N \cdot P + A$ ; this determines the values (N, A) that must be programmed into the N and A counters, respectively. P is the lower divide ratio of the dual-modulus prescaler (i.e., 32 or 64).
4. Pull-up voltage must be at the same potential as the V+ pin or less. Pull-up device other than a resistor may be used. (Pull-up device not required when Output A is configured as  $f_R$ ,  $f_R'$ ,  $f_V$ ,  $f_V'$ , DATA OUT.)
5. LD and LD' are open-drain outputs. This allows the wired-OR configuration shown. Note that R1 and Q1 form the "pull-up device".
6. Use of Q1 is optional and depends on loading.

Figure 23. Application Showing Use of Both the Single- and Double-Ended Phase/Frequency Detectors

NOTE: See related Figures 25, 26, and 27.

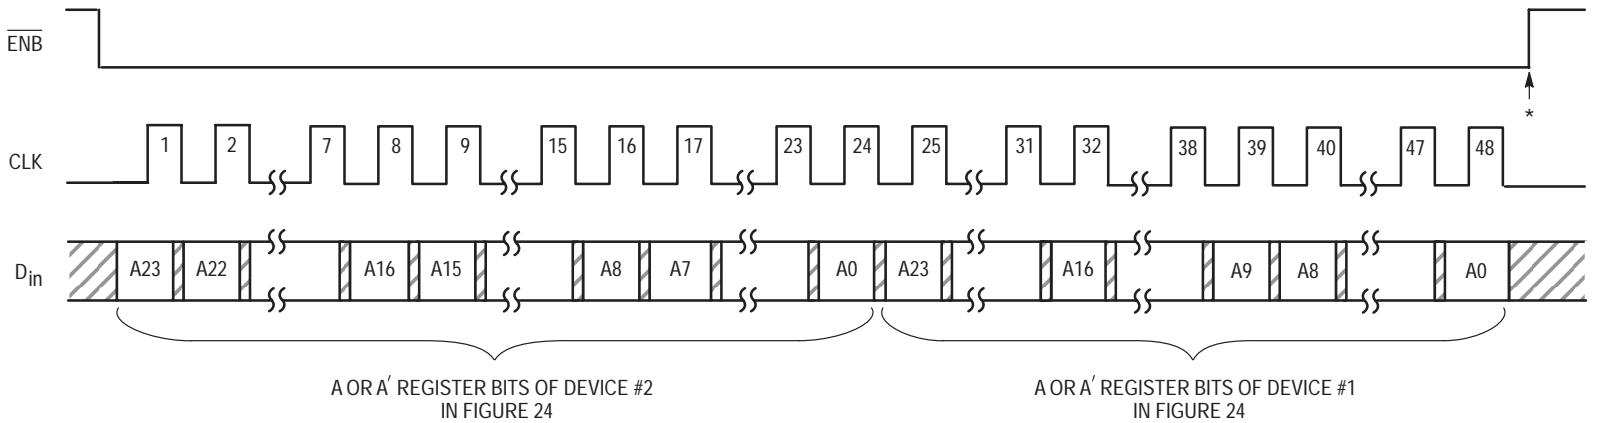

Figure 24. Cascading Two Devices

\*At this point, the new bytes are transferred to the C or C' registers of both devices and stored. No other registers are affected.

**Figure 25. Accessing the C or C' Registers of Two Cascaded MC145220 Devices (32 Clock Cycles are Used)**

**Figure 26. Accessing the A or A' Registers of  
Two Cascaded MC145220 Devices  
(48 Clock Cycles are Used)**

\*At this point, the new bytes are transferred to the A or A' registers of both devices and stored. Additionally, for both devices, the 13 LSBs in each of the first buffers of the R Registers are transferred to the respective R register's second buffer. Thus, the R, N, and A (R', N', and A') counters can be presented new divide ratios at the same time. The first buffer of each R register is not affected. None of the C or C' registers are affected.

**Figure 27. Accessing the R Registers of  
Two Cascaded MC145220 Devices  
(40 Clock Cycles are Used)**

NOTES APPLICABLE TO EACH DEVICE:

1. At this point, bits R13, R14, and R15 are stored and sent to the Buffer and Control block in the Block Diagram. Bits R0 through R12 are loaded into the first buffer in the double-buffered section of the R register. Therefore, the R and R' counter divide ratios are not altered yet and retain the previous ratios loaded. The other registers are not affected.
2. See note of Figure 26 for the method of loading the second buffers in the R register to achieve new divide ratios.

Advance Information

# Dual PLL Frequency Synthesizers with DACs and Voltage Multiplier

The MC145225 and MC145230 are dual frequency synthesizers containing very-low supply voltage circuitry. These devices support two independent loops with a single input reference and operate down to 1.8 V. Phase noise reduction circuitry is incorporated into each device.

The MC145225 is capable of direct usage up to 1.2 GHz on the main loop and up to 550 MHz on the secondary loop. The MC145230 is capable of direct usage up to 2.2 GHz on the main loop and up to 550 MHz on the secondary loop. Each device has a 32/33 prescaler for the main loop and an 8/9 prescaler for the secondary loop. Lock detection circuitry for each loop is multiplexed to a single output.

Two 8-bit DACs are powered through a dedicated pin. The DAC supply range is 1.8 to 3.6 V; this voltage may differ from the main supply.

An on-chip voltage multiplier supplies power to the phase/frequency detectors. Thus, in a 2 V application, the detectors are supplied with 4 V power. In 2.6 to 3.6 V applications, the multiplied voltage is regulated at approximately 5 V. The current source/sink phase/frequency detector for the main loop is designed to achieve faster lock times than a conventional detector. Both high and low current outputs are available along with a timer, double buffers, and a MOSFET switch to adjust the external low-pass filter response.

There are several levels of standby which are controllable with a 1-byte transfer through the serial port. Either of the PLLs and/or the reference oscillator may be independently placed in the low-power standby state. In addition, any of the phase/frequency detector outputs may be placed in the floating state to facilitate modulation of the external VCOs. Either DAC may be placed in standby via a 4-byte transfer.

- Operating Frequency
  - MC145225 — Main Loop: 100 to 1200 MHz  
Secondary Loop: 50 to 550 MHz
  - MC145230 — Main Loop: 500 to 2200 MHz  
Secondary Loop: 50 to 550 MHz
- Operating Supply Voltage: 1.8 to 3.6 V
- Nominal Supply Current, Both Loops Active — MC145225: 4 mA  
MC145230: 5 mA
- Maximum Standby Current, All Systems Shut Down: 10  $\mu$ A
- Nominal Phase Detector Output Current:
  - 1.8 V Supply — PD<sub>out</sub>-Hi: 2.8 mA, PD<sub>out</sub>-Lo: 0.7 mA
  - $\geq 2.5$  V Supply — PD<sub>out</sub>-Hi: 4.4 mA, PD<sub>out</sub>-Lo: 1.1 mA
- Two Independent 8-Bit DACs with Separate Supply Pin (Up to 3.6 V)
- Lock Detect Output with Adjustable Lock Indication Window
- Independent R Counters Allow Independent Step Sizes for Each Loop
- Main Loop Divider Range: 992 to 262,143
- Secondary Loop Divider Range: 152 to 65,535
- Fractional Reference Counters Divider Range: 20 to 32,767.5
- Auxiliary Reference Divider with Small-Signal Differential Output — Ratios: 8, 10, 12.5
- Three General-Purpose Outputs
- Direct Interface to Motorola SPI Data Port Up to 10 Mbps

BitGrabber is a trademark of Motorola, Inc.

## MC145225 MC145230

### BiCMOS COMPONENT FOR 2 OR 3 VOLT SYSTEMS

#### SEMICONDUCTOR TECHNICAL DATA

32 1  
(Scale 2:1)

PLASTIC PACKAGE  
CASE 873C  
(LQFP-32, Tape & Reel Only)  
VERY-SMALL 5 x 5 mm BODY

#### DEVELOPMENT SYSTEM

The MC145230EVK, which contains hardware and software, is strongly recommended for system development. (The user must provide the VCOs for evaluating the MC145181.) The software supports all features and modes of operation of the device. Up to four boards or devices can be controlled and the user is alerted to error conditions. The control program may be used with any board based on the MC145181, MC145225, or MC145230.

# MC145225 MC145230

## 1. BLOCK DIAGRAM

# MC145225 MC145230

## 2. PIN CONNECTIONS

This device contains 15,260 active transistors.

## 3. PARAMETER TABLES

### 3A. MAXIMUM RATINGS (Voltages Referenced to Gnd, unless otherwise stated)

Parameter	Symbol	Value	Unit
DC Supply Voltages	$V_{pos}$ , DAC $V_{pos}$	-0.5 to 3.6	V
DC Input Voltage — $Osc_e$ , $f_{in}$ , $f_{in}'$ , Mode, $D_{in}$ , Clk, $\bar{E}n_b$ , $f_{out}/Pol'$ , $\bar{f}_{out}/Pol$	$V_{in}$	-0.5 to $V_{pos} + 0.5$	V
DC Output Voltage	$V_{out}$	-0.5 to $V_{pos} + 0.5$	V
DC Input Current, per Pin	$I_{in}$	$\pm 10$	mA
DC Output Current, per Pin	$I_{out}$	$\pm 20$	mA
DC Supply Current, $V_{pos}$ and Gnd Pins	$I$	25	mA
Power Dissipation, per Package	$P_D$	100	mW
Storage Temperature	$T_{stg}$	-65 to 150	°C
Lead Temperature, 1 mm from Case for 10 Seconds	$T_L$	260	°C

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit.

- NOTES:** 1. Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the limits in the Electrical Characteristics tables or Pin Descriptions section.  
2. ESD (electrostatic discharge) immunity meets Human Body Model (HBM) up to 2000 V. Additional ESD data available upon request.

# MC145225 MC145230

## 3B. DC ELECTRICAL CHARACTERISTICS

$V_{pos} = 1.8$  to  $3.6$  V, Voltages Referenced to Gnd,  $T_A = -40$  to  $85^\circ\text{C}$ , unless otherwise stated

Parameter	Condition	Symbol	Guaranteed Limit	Unit
Maximum Low-Level Input Voltage ( $D_{in}$ , Clk, $\overline{Enb}$ , Mode, $f_{out}/Pol'$ , $\overline{f_{out}/Pol}$ )	$f_{out}/Pol'$ and $\overline{f_{out}/Pol}$ Configured as Inputs	$V_{IL}$	$0.3 \times V_{pos}$	V
Minimum High-Level Input Voltage ( $D_{in}$ , Clk, $\overline{Enb}$ , Mode, $f_{out}/Pol'$ , $\overline{f_{out}/Pol}$ )	$f_{out}/Pol'$ and $\overline{f_{out}/Pol}$ Configured as Inputs	$V_{IH}$	$0.7 \times V_{pos}$	V
Minimum Hysteresis Voltage (Clk)		$V_{Hys}$	100	mV
Maximum Low-Level Output Voltage (LD, Output A, Output B)	$I_{out} = 20 \mu\text{A}$	$V_{OL}$	0.1	V
Minimum High-Level Output Voltage (LD, Output A, Output B)	$I_{out} = -20 \mu\text{A}$	$V_{OH}$	$V_{pos} - 0.1$	V
Minimum Low-Level Output Current (LD, Output A, Output B)	$V_{out} = 0.3$ V	$I_{OL}$	0.7	mA
Minimum High-Level Output Current (LD, Output A, Output B)	$V_{out} = V_{pos} - 0.3$ V	$I_{OH}$	-0.7	mA
Minimum Low-Level Output Current (Output C)	$V_{out} = 0.2$ V	$I_{OL}$	2.8	mA
Maximum Input Leakage Current ( $D_{in}$ , Clk, $\overline{Enb}$ , Mode, $f_{out}/Pol'$ , $\overline{f_{out}/Pol}$ )	$V_{in} = V_{pos}$ or Gnd; $f_{out}/Pol'$ and $\overline{f_{out}/Pol}$ Configured as Inputs	$I_{in}$	$\pm 1.0$	$\mu\text{A}$
Maximum Output Leakage Current (Output B, Output C)	$V_{out} = V_{pos}$ or Gnd; Output in High-Impedance State	$I_{OZ}$	$\pm 1$	$\mu\text{A}$
Maximum ON Resistance (Output C)	$1.8 \text{ V} \leq V_{pos} < 2.5 \text{ V}$ Supply $2.5 \text{ V} \leq V_{pos} \leq 3.6 \text{ V}$ Supply	$R_{on}$	75 50	$\Omega$
Maximum Standby Supply Current ( $V_{pos}$ and DAC $V_{pos}$ Tied Together)	$V_{in} = V_{pos}$ or Gnd; Outputs Open; Both PLLs in Standby Mode; Oscillator in Standby Mode; DAC1 and DAC2 Output = Zero; Keep-alive Oscillator Off (Notes 1, 2, and 3)	ISTBY	10	$\mu\text{A}$

**NOTES:** 1. The total supply current drain for the keep-alive oscillator, voltage multiplier, and regulator is approximately  $250 \mu\text{A}$ .

2. When the Mode pin is tied high, bit C6 must be programmed to a 0 for minimum supply current drain. Otherwise, if C6 = 1, the current drain is approximately  $8 \mu\text{A}$  for a  $1.8$  V supply and approximately  $40 \mu\text{A}$  for a  $3.6$  V supply. This restriction on bit C6 does not apply when the Mode pin is tied low.

3. To ensure minimum standby supply current drain, the voltage potential at the  $C_{mult}$  pin must not be allowed to fall below the potential at the  $V_{pos}$  pins. See discussion in Section 5E under **C<sub>mult</sub>**.

## 3C. PD<sub>out-Hi</sub> AND PD<sub>out-Lo</sub> PHASE/FREQUENCY DETECTOR CHARACTERISTICS

Nominal Output Current,  $V_{pos} = 1.8$  V: PD<sub>out-Hi</sub> =  $2.8$  mA, PD<sub>out-Lo</sub> =  $0.7$  or  $0.35$  mA

Nominal Output Current,  $V_{pos} \geq 2.5$  V: PD<sub>out-Hi</sub> =  $4.4$  mA, PD<sub>out-Lo</sub> =  $1.1$  or  $0.55$  mA

$R_x = 2.0$  k $\Omega$ , Voltages Referenced to Gnd, Voltage Multiplier ON,  $T_A = -40$  to  $85^\circ\text{C}$

Parameter	Condition	Guaranteed Limit	Unit
Maximum Source Current Variation Part-to-Part (See Note)	$V_{out} = 0.5 \times V_{Cmult}$	$\pm 14$	%
Maximum Sink-versus-Source Mismatch (See Note)	$V_{out} = 0.5 \times V_{Cmult}$	20	%
Output Voltage Range (See Note)	$I_{out}$ Variation $\leq 27\%$	$0.6$ to $V_{Cmult} - 0.6$ V	V
Maximum Three-State Leakage Current	$V_{out} = 0$ or $V_{Cmult}$	$\pm 50$	nA

**NOTE:** Percentages calculated using the following formula: (Maximum Value - Minimum Value) / Maximum Value.

## 3D. PD<sub>out'</sub> PHASE/FREQUENCY DETECTOR CHARACTERISTICS

$V_{pos} = 1.8$  to  $3.6$  V, Voltages Referenced to Gnd, Voltage Multiplier ON,  $T_A = -40$  to  $85^\circ\text{C}$

Parameter	Condition	Guaranteed Limit	Unit
Minimum Low-Level Output Current	$V_{out} = 0.3$ V	0.3	mA
Minimum High-Level Output Current	$V_{out} = V_{Cmult} - 0.3$ V	-0.3	mA
Maximum Three-State Leakage Current	$V_{out} = 0$ or $V_{Cmult}$	$\pm 50$	nA

# MC145225 MC145230

## 3E. DAC CHARACTERISTICS

$V_{pos} = 1.8$  to  $3.6$  V, DAC  $V_{pos} = 1.8$  to  $3.6$  V;  $T_A = -40$  to  $85^\circ\text{C}$

Parameter	Condition	Guaranteed Limit	Unit
Resolution		8	Bits
Maximum Integral Nonlinearity		$\pm 1$	LSB
Maximum Offset Voltage from Gnd	No External Load	1	LSB
Maximum Offset Voltage from DAC $V_{pos}$	No External Load	2	LSB
Maximum Output Impedance	Over Entire Output Range, Including Zero Output (which is Low-power Standby)	130	k $\Omega$
Maximum Standby Current	Zero Output, No External Load	(See $I_{STBY}$ in Section 3B)	
Maximum Supply Current per DAC @ DAC $V_{pos}$ pin	Except with Zero Output, No External Load	(DAC $V_{pos}$ ) / 36	mA

## 3F. VOLTAGE MULTIPLIER AND KEEP-ALIVE OSCILLATOR CHARACTERISTICS

Voltages Referenced to Gnd,  $T_A = -40$  to  $85^\circ\text{C}$

Parameter	Condition	Guaranteed Limit	Unit
Voltage Multiplier Output Voltage	5 MHz Refresh Rate, 100 $\mu\text{A}$ Continuous Sourcing, Measured at $C_{mult}$ pin $V_{pos} = 1.8$ V $V_{pos} = 3.6$ V	3.32 to 3.78 4.75 to 5.35	V
Keep-alive Refresh Frequency	$V_{pos} = 1.8$ to $3.6$ V	300 to 700	kHz

## 3G. DYNAMIC CHARACTERISTICS OF DIGITAL PINS

$V_{pos} = 1.8$  to  $3.6$  V,  $T_A = -40$  to  $85^\circ\text{C}$ , Input  $t_r = t_f = 10$  ns,  $C_L = 25$  pF

Parameter	Figure No.	Symbol	Guaranteed Limit	Unit
Serial Data Clk Frequency NOTE: Refer to Clk $t_w$ Below	1	$f_{clk}$	dc to 10	MHz
Maximum Propagation Delay, $\overline{Enb}$ to Output A (Selected as General-Purpose Output)	2, 7	$t_{PLH}$ , $t_{PHL}$	200	ns
Maximum Propagation Delay, $\overline{Enb}$ to Output B	2, 3, 7, 8	$t_{PLH}$ , $t_{PHL}$ , $t_{PZL}$ , $t_{PLZ}$ , $t_{PZH}$ , $t_{PHZ}$	200	ns
Maximum Propagation Delay, $\overline{Enb}$ to Output C	4, 8	$t_{PZL}$ , $t_{PLZ}$	200	ns
Maximum Output Transition Time, Output A; Output B with Active Pullup and Pulldown	2, 7	$t_{TLH}$ , $t_{THL}$	75	ns
Minimum Setup and Hold Times, $D_{in}$ versus Clk	5	$t_{su}$ , $t_h$	30	ns
Minimum Setup, Hold, and Recovery Times, $\overline{Enb}$ versus Clk	6	$t_{su}$ , $t_h$ , $t_{rec}$	100	ns
Minimum Pulse Width, Inactive (High) Time, $\overline{Enb}$	6	$t_w$	*	cycles
Minimum Pulse Width, Clk	1	$t_w$	50	ns
Maximum Input Capacitance — $D_{in}$ , CLK, $\overline{Enb}$		$C_{in}$	10	pF

\*For Hr register access, the minimum limit is 20  $Osc_e$  cycles.

For Hn' register access, the minimum limit is 27  $f_{in'}$  cycles.

For N register access, the minimum limit is 20  $Osc_e$  cycles + 99  $f_{in}$  cycles.

When the timer is used for adapt, the minimum limit after the second N register access and before the next register access is the time-out interval + 99  $f_{in}$  cycles.

## 4. DEVICE OVERVIEW

Refer to the Block Diagram in Section 1.

### 4A. SERIAL INTERFACE AND REGISTERS

The serial interface is comprised of a Clock pin (Clk), a Data In pin ( $D_{in}$ ), and an Enable pin ( $\overline{Enb}$ ). Information on the data input pin is shifted into a shift register on the low-to-high transition of the serial clock. The data format is most significant bit (MSB) first. Both Clk and  $\overline{Enb}$  are Schmitt-triggered inputs.

The R and N registers contain counter divide ratios for the main loop, PLL. The R' and N' registers contain counter divide ratios for the secondary loop, PLL'. Additional control bits are located in the R', N, and C registers. The D register controls the digital-to-analog converters (DACs). Random access is allowed to the N, R', Hr, Hn', D, and C registers.

Two 16-bit holding registers, Hr and Hn', feed registers R and N', respectively. The R and N' registers determine the divide ratios of the R and N' counters, respectively. Thus, the information presented to the R and N' counters is double-buffered. Using the proper programming sequence, new divide ratios may be presented to the N, R, and N' counters; simultaneously.

$\overline{Enb}$  is used to activate the data port and allow transfer of data. To ensure that data is accepted by the device, the  $\overline{Enb}$  signal line must initially be a high voltage (not asserted), then make a transition to a low voltage (asserted) prior to the occurrence of a serial clock, and must remain asserted until after the last serial clock of the burst. Serial data may be transferred in an SPI format (while  $\overline{Enb}$  remains asserted). Data is transferred to the appropriate register on the rising edge of  $\overline{Enb}$  (see Table 1). "Short shifting", depicted as BitGrabber™ in the table, allows access to certain registers without requiring address bits. When  $\overline{Enb}$  is inactive (high), Clk is inhibited from shifting the shift register.

The serial input pins may NOT be driven above the supply voltage applied to the  $V_{POS}$  pins.

### 4B. REFERENCE INPUT AND COUNTERS CIRCUITS

#### Reference (Oscillator) Circuit

For the Colpitts reference oscillator, one pin ties to the base (Osc<sub>b</sub>, pin 32) and the other ties to the emitter (Osc<sub>e</sub>, pin 1), of an on-chip NPN transistor. In addition, the reference circuit may be operated in the external reference (XRef) mode as selectable via bit C6 when the Mode pin is high.

The Osc<sub>b</sub> and Osc<sub>e</sub> pins support an external fundamental or overtone crystal. The output of the oscillator is routed to both the reference counter for the main loop (R counter) and the reference counter for the secondary loop (R' counter).

In a second mode, determined by bit C6 being 1 and the Mode pin being high, Osc<sub>e</sub> is an input which accepts an ac-coupled signal from a TCXO or other source. Osc<sub>b</sub> must be floated. If the Mode pin is low, this "XRef mode" is not allowed.

#### Reference Counter for Main Loop

Main reference counter R divides down the frequency at Osc<sub>e</sub> and feeds the phase/frequency detector for the main

loop. The detector feeds the two charge pumps with outputs PD<sub>OUT-Hi</sub> and PD<sub>OUT-Lo</sub>. The division ratio of the R counter is determined by bits in the R register.

#### Reference Counter for Secondary Loop

Secondary reference counter R' divides down the frequency at Osc<sub>e</sub> and feeds the phase/frequency detector for the secondary loop. The detector output is PD<sub>OUT'</sub>. The division ratio of the R' counter is determined by the 16 LSBs of the R' register.

The R' counter has a special mode to provide a frequency output at pins f<sub>OUT</sub> and  $\overline{f}_{OUT}$  (differential outputs). These are low-jitter ECL-type outputs. With the Mode pin low, software control allows the Osc<sub>e</sub> frequency to be divided-by-8, -10, or -12.5 and routed to the f<sub>OUT</sub> pins. This output is derived by tapping off of a front-end stage of the R' counter and feeding the auxiliary counter which provides the divided-down frequency. The chip must have the Mode pin low, which activates the f<sub>OUT</sub> pins. The actual R' divide ratio must be divisible by 2 or 2.5 when the f<sub>OUT</sub> pins are activated. There is no such restriction when the Mode pin is high. See Section 6D, R' Register.

### 4C. LOOP DIVIDER INPUTS AND COUNTER CIRCUITS

#### f<sub>IN</sub> Inputs and Counter Circuit

f<sub>IN</sub> and  $\overline{f}_{IN}$  are high-frequency inputs to the amplifier which feeds the N counter. A small signal can feed these inputs either differentially or single-ended.

The N counter divides down the external VCO frequency for the main loop. (The divide ratio of the N counter is also known as the loop multiplying factor.) The divide ratio of this counter is determined by the 18 LSBs of the N register. The output of the N counter feeds the phase/frequency detector for the main loop.

#### f<sub>IN'</sub> Input and Counter Circuit

f<sub>IN'</sub> is the high-frequency input to the amplifier which feeds the N' counter. A small signal can feed this input single-ended.

The N' counter divides down the external VCO frequency for the secondary loop. (The divide ratio of the N' counter is also known as the loop multiplying factor.) The divide ratio of this counter is determined by bits in the N' register. The output of the N' counter feeds the phase/frequency detector for the secondary loop.

### 4D. VOLTAGE MULTIPLIER AND KEEP-ALIVE CIRCUITS

The voltage multiplier produces approximately two times the voltage present at the  $V_{POS}$  pins over a supply range of 1.8 V to about 2.5 V. With a supply range of approximately 2.5 V to 3.6 V, the elevated voltage is regulated/limited to approximately 5 V. The elevated voltage, present at the C<sub>MULT</sub> pin, is applied to both phase detectors. An external capacitor to Gnd is required on the C<sub>MULT</sub> pin. The other capacitors required for the multiplier are on-chip.

A capacitor to Gnd is also required on the C<sub>REG</sub> pin. The voltage on this pin is equal to the voltage on the  $V_{POS}$  pins over a supply range of 1.8 V to about 2.5 V. The voltage on

$C_{reg}$  is limited to approximately 2.5 V maximum when the  $V_{pos}$  pins exceed 2.5 V.

The refresh rate determines the repetition rate that the capacitors for the voltage multiplier are charged. Refresh is normally derived off of the signal present at the  $Osc_e$  pin, through a divider which is part of the voltage multiplier and regulator circuitry. The refresh rate is controlled via bits in the R' register.

When the reference oscillator circuit is placed in standby, an on-chip keep-alive oscillator assists in maintaining the elevated voltage on the phase detectors. The keep-alive refresh rate is per the spec table in Section 3F.

If desired, the keep-alive oscillator can be inhibited from turning on, by placing the multiplier in the inactive state via R' register bits. This causes the phase/frequency detector voltage to bleed off while in standby, but has the advantage of achieving the lowest supply current if all other sections of the chip are shut down.

#### 4E. PHASE/FREQUENCY DETECTORS

##### Detector for Main Loop

The detector for the main loop senses the phase and frequency difference between the outputs of the R and N counters. The detector feeds both a high-current charge pump with output  $PD_{out-Hi}$  and a low-current charge pump with output  $PD_{out-Lo}$ .

The charge pumps can be operated in three conventional manners as controlled by bits in the N register.  $PD_{out-Lo}$  can be enabled with  $PD_{out-Hi}$  inhibited. Conversely,  $PD_{out-Hi}$  can be enabled with  $PD_{out-Lo}$  inhibited. Both outputs can be enabled and tied together externally for maximum charge pump current. Finally, both outputs can be inhibited. In this last case, they float. The outputs can also be forced to the floating state by a bit in the C register. This facilitates introduction of modulation into the VCO input.

The charge pumps can be operated in an adapt mode as controlled by bits in the N register. The bits essentially program a timer which determines how long  $PD_{out-Hi}$  is active. After the time-out,  $PD_{out-Hi}$  floats and  $PD_{out-Lo}$  becomes active. In addition, a second set of R and N counter values can be engaged after the time-out. For more information, see Table 16 and Section 8, **Programmer's Guide**.

##### Detector for Secondary Loop

The detector for the secondary loop senses the phase and frequency difference between the outputs of the R' and N'

counters. Detector output  $PD_{out}'$  is a voltage-type output with a three-state push-pull driver.

The output can be forced to the floating state by a bit in the C register. This facilitates introduction of modulation into the VCO input.

#### 4F. LOCK DETECTORS

Window counters in each of the lock detector circuits determine the lock detector phase threshold for PLL and PLL'. The window counter divide ratio for the main loop's lock detector is controlled via a bit in the N register. The window counter divide ratio for the secondary loop is not controllable by the user.

The lock detector window determines a minimum phase difference which must occur before the Lock Detect pin goes high. Note that the lock detect signals for each loop drive an AND gate, which then feeds the LD pin. The LD pin indicates the condition of both loops, or the one active loop if the other is in standby. If both loops are in standby, LD is low indicating unlocked.

#### 4G. DACs

The two independent 8-bit DACs facilitate crystal oscillator trimming and PA output power control. They are also suitable for any general-purpose use.

Each DAC utilizes an R-2R ladder architecture. The output pins, DAC1 and DAC2, are directly connected to the ladder; that is, there is no on-chip buffer.

The DAC outputs are determined by the contents of the D register. When a DAC output is zero scale, it is also in a low-power mode. The power-on reset (POR) circuit initializes the DACs in the low-power mode upon power up.

#### 4H. GENERAL-PURPOSE OUTPUTS

There are three outputs which may be used as port expanders for a microcontroller unit (MCU).

Output A is actually a multi-purpose output with a push-pull output driver. See Table 2 for details.

Output B is a three-state output. The state of Output B depends on two bits; one of these bits also controls whether the main PLL is in standby or not. See Table 5 for details.

Output C is an open-drain output. The state of this output is controlled by one bit per Table 4. Output C is specified with a guaranteed ON resistance, and thus, may be used in an analog fashion.

## 5. PIN DESCRIPTIONS

## 5A. DIGITAL PINS

 $\overline{\text{Enb}}$ ,  $\text{D}_{\text{in}}$ , and  $\text{Clk}$ 

## Pins 5, 6, and 7 — Serial Data Port Inputs

The  $\overline{\text{Enb}}$  input is used to activate the serial interface to allow the transfer of data to the device. To transfer data to the device, the  $\overline{\text{Enb}}$  pin must be low during the interval that the data is being clocked in. When  $\overline{\text{Enb}}$  is taken back high (inactive), data is transferred to the appropriate register depending either on the data stream length or address bits. The C, Hr, and N registers can be accessed using either a unique data stream length (BitGrabber) or by using address bits (Conventional). The D,  $\text{Hn}'$ , and  $\text{R}'$  registers can only be accessed using address bits. See Table 1.

The bit stream begins with the MSB and is shifted in on the low-to-high transition of  $\text{Clk}$ . The bit pattern is 1 byte (8 bits) long to access the C register, 2 bytes (16 bits) to access the Hr register, or 3 bytes (24 bits) to access the N register. A bit pattern of 4 bytes (32 bits) is used to access the registers when using address bits. The device has double buffers for storage of the  $\text{N}'$  and R counter divide ratios. One double buffer is composed of the Hr register which feeds the R register. An Hr to R register transfer occurs whenever the N register is written. The other double buffer is the  $\text{Hn}'$  register which feeds the  $\text{N}'$  register. An  $\text{Hn}'$  to  $\text{N}'$  register transfer occurs whenever the N register is written. Thus, new divide ratios may be presented to the R,  $\text{N}'$ , and N counters simultaneously.

Transitions on  $\overline{\text{Enb}}$  must not be attempted while  $\text{Clk}$  is high. This puts the device out of synchronization with the microcontroller. Resynchronization occurs whenever  $\overline{\text{Enb}}$  is high (inactive) and  $\text{Clk}$  is low.

Data is retained in the registers over a supply range of 1.8 to 3.6 V. The bit-stream formats are shown in Figures 13 through 18.

## LD

## Pin 8 — Lock Detectors Output

This signal is the logical AND of the lock detect signals from both PLL and  $\text{PLL}'$ . For the main PLL, the phase window that defines “lock” is programmable via bit N22. The phase window for the secondary  $\text{PLL}'$  is not programmable.

If either PLL or  $\text{PLL}'$  is in standby, LD indicates the lock condition of the active loop only. If both loops are in standby, the LD output is a static low level.

Each PLL's lock detector is in the high state when the respective loop is locked (the inputs to the phase detector being the same phase and frequency). The lock detect signal is in the low state when a loop is out of lock. See Figure 19.

Upon power up, the LD pin indicates a *not locked* condition. The LD pin is a push-pull CMOS output. If unused, LD should be left open.

## Output A

## Pin 9 — Multiple-Purpose Digital Output

Depending on control bits  $\text{R}'21$  and  $\text{R}'20$ , Output A is selectable by the user as a general-purpose output (either high or low level),  $f_{\text{R}}$  (output of main reference counter),  $f_{\text{R}'}$  (output of secondary reference counter), or a phase detector pulse indicator for both loops. When selected as general-purpose output, bit C7 determines whether the output is a high or low level per Table 2. When configured as  $f_{\text{R}}$ ,  $f_{\text{R}'}$ , or phase detector pulse, Output A appears as a normally low signal and pulses high.

Output A is a slow-rate limited CMOS totem-pole output. If unused, Output A should be left open.

**Table 1. Register Access**  
(LSBs are C0, R0, N0, D0,  $\text{R}'0$ , and  $\text{N}'0$ )

Access Type	Accessed Register	Address Nibble	Number of Clocks	Register Bit Nomenclature	Figure No.
BitGrabber	C	—	8	C7, C6, C5, ..., C0	13
BitGrabber	Hr	—	16	R15, R14, R13, ..., R0	14
BitGrabber	N	—	24	N23, N22, N21, ..., N0	15
Conventional	C	\$0	32	C7, C6, C5, ..., C0	13
Conventional	Hr	\$1	32	R15, R14, R13, ..., R0	14
Conventional	N	\$2	32	N23, N22, N21, ..., N0	15
Conventional	D	\$3	32	D15, D14, D13, ..., D0	18
Conventional	$\text{R}'$	\$5	32	$\text{R}'23$ , $\text{R}'22$ , $\text{R}'21$ , ..., $\text{R}'0$	16
Conventional	$\text{Hn}'$	\$4	32	$\text{N}'15$ , $\text{N}'14$ , $\text{N}'13$ , ..., $\text{N}'0$	17

**NOTE:** \$0 denotes hexadecimal zero, \$1 denotes hexadecimal one, etc.

**Table 2. Output A Configuration**

Bit R'21	Bit R'20	Bit C7	Function of Output A
0	0	0	General-Purpose Output, Low Level
0	0	1	General-Purpose Output, High Level
0	1	x	f <sub>R</sub>
1	0	x	f <sub>R'</sub>
1	1	x	Phase Detector Pulse Indicator

**Mode**

**Pin 10 — Mode Input**

When the Mode pin is tied low (approximately Gnd), the pair of pins named f<sub>out</sub>/Pol' and f<sub>out</sub>/Pol become outputs f<sub>out</sub> and f<sub>out</sub>. As such, these pins are the divided down reference frequency. The division ratio is controlled by bits per Table 6. In addition, when Mode is low, the R' counter is preceded by a fixed-divide prescaler. Also, only a crystal may be used at pins Osc<sub>B</sub> and Osc<sub>E</sub>; an external reference, such as a TCXO, should not be used to drive either pin. The default on the phase detector polarity is positive. See the summary in Table 3.

When the Mode pin is tied high (approximately V<sub>POS</sub>), the pair of pins named f<sub>out</sub>/Pol' and f<sub>out</sub>/Pol become inputs Pol' and Pol. As such, these pins control the polarity of the phase/frequency detectors for PLL' and PLL, respectively. In addition, when Mode is high, the R' counter is preceded by a dual-modulus prescaler. Therefore, the R' counter is completely programmable per Figure 16. Also, either a crystal or TCXO may be used with the device. See the summary in Table 3.

**Table 3. Mode Pin Summary**

Attribute	Mode Pin = Low Level	Mode Pin = High Level
f <sub>out</sub> /Pol' pin	Pin is f <sub>out</sub> output; polarity of phase detector' is positive	Pin is Pol' input and controls polarity of phase detector'
f <sub>out</sub> /Pol pin	Pin is f <sub>out</sub> output; polarity of phase detector is positive	Pin is Pol input and controls polarity of phase detector
Oscillator circuit	Supports a crystal only	Supports crystal or accommodates TCXO
R' counter	Programmable in increments of 2 or 2.5	Programmable in increments of 0.5
Output B pin	State of pin controlled by Bit C6	Pin not used, Bit C6 controls whether crystal or TCXO is accommodated

**Output C**

**Pin 16 — General-Purpose Digital Output**

This pin is controllable by bit C5 as either low level or high impedance per Table 4.

The output driver is an open-drain N-channel MOSFET connected to Gnd. The ESD (electrostatic discharge) protection circuit for this pin is tied to Gnd and V<sub>POS</sub>. Thus,

voltages above V<sub>POS</sub> are clipped at approximately 0.7 V above V<sub>POS</sub>. If unused, Output C should be left open.

**Table 4. Output C Programming**

Bit C5	State of Output C Pin
0	Low level (ON resistance per Electrical Table)
1	High impedance (leakage per Electrical Table)

**Output B**

**Pin 25 — General-Purpose Digital Output**

This pin is controllable by bits C6 and C1 as either low level, high level, or high impedance per Table 5. Note that whenever the main PLL is placed in standby by bit C1, Output B is forced to high impedance. The three-state MOSFET output is slew-rate limited. If unused, Output B should be left open.

**Table 5. Output B Programming**

Bit C6	Bit C1	State of Output B Pin	Condition of Main PLL
0	0	Low level	Active
0	1	High impedance*	Standby*
1	0	High level	Active
1	1	High impedance	Standby

\*Power-up default.

**f<sub>out</sub>/Pol' and f<sub>out</sub>/Pol**

**Pins 28 and 27 — Dual-purpose Outputs/Inputs**

These pins are outputs when the Mode pin is low and inputs when the Mode pin is high.

When the Mode pin is low, these pins are small-signal differential outputs f<sub>out</sub> and f<sub>out</sub> with a frequency derived from the signal present at the Osc<sub>E</sub> pin. The frequency of the output signal is per Table 6. If this function is not needed, the Mode pin should be tied high, which minimizes supply current. In this case, these inputs must be tied high or low per Tables 7 and 8.

**Table 6. f<sub>out</sub> and f<sub>out</sub> Frequency (Mode Pin = Low)**

Bit N23	Bit R'1	Bit R'0	Output Frequency
0	0	0	Osc <sub>E</sub> divided by 10
0	0	1	Osc <sub>E</sub> divided by 12.5
0	1	0	Osc <sub>E</sub> divided by 12.5
0	1	1	Osc <sub>E</sub> divided by 12.5
1	0	0	Osc <sub>E</sub> divided by 8
1	0	1	Osc <sub>E</sub> divided by 10
1	1	0	Osc <sub>E</sub> divided by 10
1	1	1	Osc <sub>E</sub> divided by 10

When the Mode pin is high, these pins are digital inputs Pol' and Pol which control the polarity of the phase/frequency detectors. See Tables 7 and 8. Positive polarity is used when an increase in an external VCO control voltage input causes an increase in VCO output frequency. Negative polarity is used when a decrease in an external VCO control voltage input causes an increase in VCO output frequency.

**Table 7. Main Phase/Frequency Detector Polarity (Mode Pin = High)**

Mode Pin	Pol Pin	Main Detector Polarity (PD <sub>out-Lo</sub> and PD <sub>out-Hi</sub> )
High	Low	Positive
High	High	Negative
Low	*	Positive

\*Pin configured as an output; should not be driven.

**Table 8. Secondary Phase/Frequency Detector Polarity (Mode Pin = High)**

Mode Pin	Pol' Pin	Secondary Detector Polarity (PD <sub>out'</sub> )
High	Low	Positive
High	High	Negative
Low	*	Positive

\*Pin configured as an output; should not be driven.

**5B. REFERENCE PINS**

**Osc<sub>e</sub> and Osc<sub>b</sub>**

**Pins 1 and 32 — Reference Oscillator Transistor Emitter and Base**

These pins can be configured to support an external crystal in a Colpitts oscillator configuration. The required connections for the crystal circuit are shown in the **Crystal Oscillator Considerations** section.

Additionally, the pins can be configured to accept an external reference frequency source, such as a TCXO. In this case, the reference signal is ac coupled into Osc<sub>e</sub> and the Osc<sub>b</sub> pin is left floating. See Figure 11.

Bit C6 and the Mode input pin control the configuration of these pins per Table 9.

**Table 9. Reference Configuration**

Mode Input Pin	Bit C6	Reference Configuration	Comment
Low	X	Supports Crystal (default)	C6 used to control Output B*
High	0	Supports Crystal	Output B not useful
High	1	Requires External Reference	Output B not useful

\*See Table 5.

**5C. LOOP PINS**

**f<sub>in</sub> and f<sub>in</sub>'**

**Pins 12 and 13 — Frequency Input for Main Loop (PLL)**

These pins feed the on-chip RF amplifier which drives the high-speed N counter. This input may be fed differentially. However, it is usually used in a single-ended configuration with f<sub>in</sub> driven while f<sub>in</sub>' is tied to a good RF ground (via a capacitor). The signal source driving this input must be ac coupled and originates from an external VCO.

The sensitivity of the RF amplifier is dependent on frequency as shown in the Loop Specifications table. Sensitivity of the f<sub>in</sub> input is specified as a level across a 50 Ω load driven by a 50 Ω source. A VCO that can drive a load within the data sheet limits can also drive f<sub>in</sub>. Usually, to avoid load pull and resultant frequency modulation of the VCO, f<sub>in</sub> is lightly coupled by a small value capacitor and/or a resistor. See the applications circuit of Figure 65.

**f<sub>in</sub>'**

**Pin 30 — Frequency Input for Secondary Loop (PLL')**

This pin feeds the on-chip RF amplifier which drives the high-speed N' counter. This input is used in a single-ended configuration. The signal source driving this input must be ac coupled and originates from an external VCO.

The sensitivity of the RF amplifier is dependent on frequency as shown in the Loop Specifications table. Sensitivity of the f<sub>in</sub>' input is specified as a level across a 50 Ω load driven by a 50 Ω source. A VCO that can drive a load within the data sheet limits can also drive f<sub>in</sub>'. Usually, to avoid load pull and resultant frequency modulation of the VCO, f<sub>in</sub>' is lightly coupled by a small value capacitor and/or a resistor. See the applications circuit of Figure 65.

If the secondary loop is not used, PLL' should be placed in standby and f<sub>in</sub>' should be left open.

**PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub>**

**Pins 19 and 20 — Phase/Frequency Detector Outputs for Main Loop (PLL)**

Each pin is a three-state current source/sink/float output for use as a loop error signal when combined with an external low-pass loop filter. Under bit control, PD<sub>out-Lo</sub> has either one-quarter or one-eighth the output current of PD<sub>out-Hi</sub> per Table 10. The detector is characterized by a linear transfer function (no dead zone). The polarity of the detector is controllable. The operation of the detector is described below and shown in Figure 20.

**Table 10. Current Ratio of PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub>**

Bit N18	Output Current Ratio PD <sub>out-Hi</sub> :PD <sub>out-Lo</sub> (Gain Ratio)
0	4 : 1
1	8 : 1

When the Mode pin is high, positive polarity occurs when the Pol pin is low. Also, when the Mode pin is low, polarity

defaults to positive. Positive polarity is described below.  $f_V$  is the output of the main loop's VCO divider (N counter).  $f_R$  is the output of the main loop's reference divider (R counter).

- (a) Frequency of  $f_V > f_R$  or phase of  $f_V$  leading  $f_R$ : current-sinking pulses from a floating state.
- (b) Frequency of  $f_V < f_R$  or phase of  $f_V$  lagging  $f_R$ : current-sourcing pulses from a floating state.
- (c) Frequency and phase of  $f_V = f_R$ : essentially a floating state, voltage at pin determined by loop filter.

When the Mode pin is high, negative polarity occurs when the Pol pin is high. Negative polarity is described below.  $f_V$  is the output of the main loop's VCO divider (N counter).  $f_R$  is the output of the main loop's reference divider (R counter).

- (a) Frequency of  $f_V > f_R$  or phase of  $f_V$  leading  $f_R$ : current-sourcing pulses from a floating state.
- (b) Frequency of  $f_V < f_R$  or phase of  $f_V$  lagging  $f_R$ : current-sinking pulses from a floating state.
- (c) Frequency and phase of  $f_V = f_R$ : essentially a floating state, voltage at pin determined by loop filter.

These outputs can be enabled and disabled by bits in the C and N registers. Placing the main PLL in standby (bit C1 = 1) forces the detector outputs to a floating state. In addition, setting the PD Float bit (bit C4 = 1) forces the detector outputs to a floating state while allowing the counters to run for the main PLL. For selection of the outputs, see Table 11.

The phase detector gain (in amps per radian) =  $PD_{out}$  current (in amps) divided by  $2\pi$ .

If a detector output is not used, that pin should be left open.

**Table 11. Selection of Main Detector Outputs**

Bit N21	Bit N20	Bit N19	Result
0	0	0	Both outputs not enabled
0	0	1	PD <sub>out-Lo</sub> enabled
0	1	0	PD <sub>out-Hi</sub> enabled
0	1	1	Both PD <sub>out-Lo</sub> and PD <sub>out-Hi</sub> enabled
1	0	0	PD <sub>out-Hi</sub> enabled for 16 $f_R$ cycles only, then PD <sub>out-Lo</sub> enabled
1	0	1	PD <sub>out-Hi</sub> enabled for 32 $f_R$ cycles only, then PD <sub>out-Lo</sub> enabled
1	1	0	PD <sub>out-Hi</sub> enabled for 64 $f_R$ cycles only, then PD <sub>out-Lo</sub> enabled
1	1	1	PD <sub>out-Hi</sub> enabled for 128 $f_R$ cycles only, then PD <sub>out-Lo</sub> enabled

- NOTES:** 1. When a detector output is not enabled, it is floating.  
 2. Setting bit N21 = 1 places the IC in an adapt mode and engages a timer.

**PD<sub>out'</sub>**  
**Pin 23 — Phase/Frequency Detector Output for Secondary Loop (PLL')**

This pin is a three-state voltage output for use as a loop error signal when combined with an external low-pass loop filter. The detector is characterized by a linear transfer function (no dead zone). The polarity of the detector is controllable. The operation of the detector is described below and shown in Figure 21.

When the Mode pin is high, positive polarity occurs when the Pol' pin is low. Also, when the Mode pin is low, polarity defaults to positive. Positive polarity is described below.  $f_V'$  is the output of the secondary loop's VCO divider (N' counter).  $f_R'$  is the output of the secondary loop's reference divider (R' counter.)

- (a) Frequency of  $f_V' > f_R'$  or phase of  $f_V'$  leading  $f_R'$ : negative pulses from high impedance.
- (b) Frequency of  $f_V' < f_R'$  or phase of  $f_V'$  lagging  $f_R'$ : positive pulses from high impedance.
- (c) Frequency and phase of  $f_V' = f_R'$ : essentially a high-impedance state, voltage at pin determined by loop filter.

When the Mode pin is high, negative polarity occurs when the Pol' pin is high. Negative polarity is described below.  $f_V'$  is the output of the secondary loop's VCO divider (N' counter).  $f_R'$  is the output of the secondary loop's reference counter (R' counter.)

- (a) Frequency of  $f_V' > f_R'$  or phase of  $f_V'$  leading  $f_R'$ : positive pulses from high impedance.
- (b) Frequency of  $f_V' < f_R'$  or phase of  $f_V'$  lagging  $f_R'$ : negative pulses from high impedance.
- (c) Frequency and phase of  $f_V' = f_R'$ : essentially a high-impedance state, voltage at pin determined by loop filter.

This output can be enabled and disabled by bits in the C register. Placing the secondary PLL' in standby (bit C0 = 1) forces the detector output to a high-impedance state. In addition, setting the PD' Float bit (bit C3 = 1) forces the detector output to a high-impedance state while allowing the counters to run for PLL'.

The phase detector gain (in volts per radian) =  $C_{mult}$  voltage (in volts) divided by  $4\pi$ .

If the secondary loop is not used, PLL' should be placed in standby and PD<sub>out'</sub> should be left open.

**5D. ANALOG OUTPUTS**

**DAC1 and DAC2**  
**Pins 3 and 4 — Digital-to-Analog Converter Outputs**

These are independent outputs of the two 8-bit D/A converters. The output voltage is determined by bits in the D register. Each output is a static level with an output impedance of approximately 100 kΩ.

The DACs may be used for crystal oscillator trimming, PA (power amplifier) output power control, or other general-purpose use.

If a DAC output is not used, the pin should be left open.

## 5E. EXTERNAL COMPONENTS

**R<sub>x</sub>****Pin 17 — Current–Setting Resistor**

An external resistor to Gnd at this pin sets a reference current that is used to determine the current at the phase/frequency detector outputs PD<sub>Out–Hi</sub> and PD<sub>Out–Lo</sub>. A value of 2 k $\Omega$  is required.

**C<sub>mult</sub>****Pin 21 — Voltage–Multiplier Capacitor**

An external capacitor to Gnd at this pin is used for the on–chip voltage multiplier circuit. The value of this capacitor must be greater than 20 times the value of the largest loop filter capacitor. For example, if the largest loop filter capacitor on either the main loop or the secondary loop is 0.01  $\mu$ F, then a 0.22  $\mu$ F capacitor could be used on the C<sub>mult</sub> pin.

To ensure minimum standby supply current drain, the voltage potential at the C<sub>mult</sub> pin must not be allowed to fall below the potential at the V<sub>pos</sub> pins. Therefore, if the keep–alive oscillator is shut off, the user should tie a large value resistor (> 10 M $\Omega$ ) between the C<sub>mult</sub> pin and V<sub>pos</sub>. This resistor should be sized to overcome leakage from C<sub>mult</sub> to Gnd due to the printed circuit board and the external capacitor. The consequence of not using the resistor is higher supply current drain in standby. If standby is not used, the resistor is not necessary. Also, if the keep–alive oscillator is used, the resistor can be omitted.

**C<sub>reg</sub>****Pin 22 — Regulator Capacitor**

An external capacitor to Gnd at this pin is required for the on–chip voltage regulator. A value of 1  $\mu$ F is recommended.

## 5F. SUPPLY PINS

**DAC V<sub>pos</sub>****Pin 2 — Positive Supply Potential for DACs**

This pin supplies power to both DACs and determines the full–scale output of the DACs. The full–scale output is approximately equal to the voltage at DAC V<sub>pos</sub>. The voltage applied to this pin may be more, less, or equal to the potential applied to the V<sub>pos</sub> pins. The voltage range for DAC V<sub>pos</sub> is 1.8 to 3.6 V with respect to the Gnd pins.

If both DACs are not used, DAC V<sub>pos</sub> should be tied to the same potential as V<sub>pos</sub>.

**V<sub>pos</sub>****Pins 11, 24, 26, and 29 — Principal Positive Supply Potential**

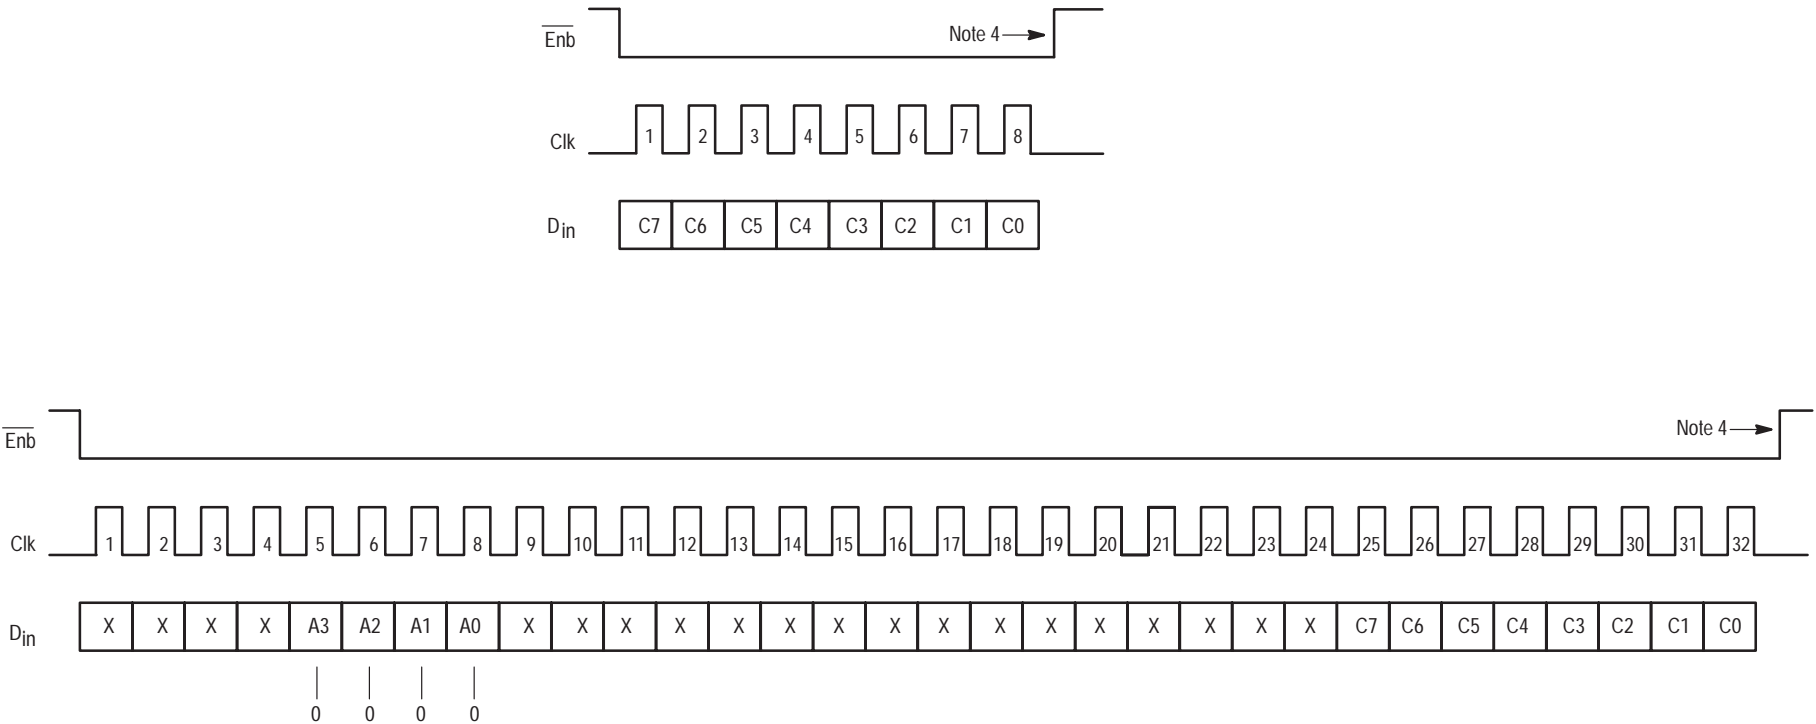

These pins supply power to the main portion of the chip. All V<sub>pos</sub> pins must be at the same voltage potential. The voltage range for V<sub>pos</sub> is 1.8 to 3.6 V with respect to the Gnd pins.

For optimum performance, all V<sub>pos</sub> pins should be tied together and bypassed to a ground plane using a low–inductance capacitor mounted very close to the device. Lead lengths and printed circuit board traces between the capacitor and the IC package should be minimized. (The very–fast switching speed of the device can cause excessive current spikes on the power leads if they are improperly bypassed.)

**Gnd****Pins 14, 15, 18, and 31 — Ground**

Common ground for the device. All Gnd pins must be at the same potential and should be tied to a ground plane.

Figure 13. C Register Access and Formats

**NOTES:**

1. To access the C register, either 8 or 32 clock cycles can be used.
2. For the 8-bit stream, no address bits are needed.
3. For the 32-bit stream, address bits A3 through A0 are required.
4. At this point, the new byte is transferred to the C register. No other register is affected.
5. X signifies a don't care bit.

**C REGISTER BITS**

See Figure 13 for C register access and serial data formats.

**Out A (C7)**

When the Output A pin is selected as a General-Purpose Output (via bits R'21 = R'20 = 0), bit C7 determines the state of the pin. When C7 is 1, Output A is forced to a high level. When C0 is 0 Output A is forced low.

When Output A is not selected as a General-Purpose Output, bit C7 has no function; i.e., C7 is a “don't care” bit.

**Out B/XRef (C6)**

Bit C6 is a dual-purpose bit.

When the Mode pin is tied low, C6 and C1 (PLL Stby), can be used to control Output B. See Table 12. (The reference circuit defaults to crystal configuration.)

When the Mode pin is tied high, additional control of the reference circuit is allowed. See Table 13.

**Table 12. Out B/XRef Bit with Mode Pin = Low**

Bit C6	Bit C1	State of Output B Pin	Condition of Main PLL
0	0	Low level	Active
0*	1*	High impedance*	Standby*
1	0	High level	Active
1	1	High impedance	Standby

\*Power up default.

**Table 13. Out B/XRef Bit with Mode Pin = High**

Bit C6	Reference Configuration
0*	Supports Crystal*
1	Accommodates External Reference

\*Power up default.

**Out C (C5)**

This bit determines the state of the Output C pin. When C5 is 1, Output C is forced to a high-impedance state. When C5 is 0, Output C is forced low.

**PD Float (C4)**

This bit controls the phase detector for the main loop, outputs PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub>. When this bit is 0, the main phase detector operates normally. When the bit is 1, the outputs are forced to the floating state which opens the loop and allows modulation to be introduced into the external VCO input. During this time, the counters are still active. This bit is inhibited from affecting the phase detector during a PD<sub>out-Hi</sub> or PD<sub>out-Lo</sub> pulse.

If the loop is locked prior to C4 being set to 1, the lock detect signal from the main loop continues to indicate “lock” immediately after PD Float is set to 1. If the phase of the loop drifts outside the lock detect window, then the lock detect signal indicates “not locked”. If the loop is not locked, and PD Float is set to 1, then the lock detect signal from the main loop continues to indicate “not locked”.

**PD' Float (C3)**

This bit controls the phase/frequency detector for the secondary loop, output PD<sub>out'</sub>. When this bit is 0, the secondary phase detector operates normally. When the bit is 1, the output is forced to the floating state which opens the loop and allows modulation to be introduced into the external VCO input. During this time, the counters are still active. This bit is inhibited from affecting the phase detector during a PD<sub>out'</sub> pulse.

If the loop is locked prior to C3 being set to 1, the lock detect signal from the secondary loop continues to indicate “lock” immediately after PD' Float is set to 1. If the phase of the loop drifts outside the lock detect window, then the lock detect signal indicates “not locked”. If the loop is not locked, and PD' Float is set to 1, then the lock detect signal from the secondary loop continues to indicate “not locked”.

**Osc Stby (C2)**

This bit controls the crystal oscillator and external reference input circuit. When this bit is 0, the circuit is active. When the bit is 1, the circuit is shut down and is in the low-power standby mode. When this circuit is shut down, a keep-alive oscillator for the voltage doubler is activated, unless the doubler is shut off via bits in the R' register. In the crystal oscillator mode, when C2 transitions from a 1 to a 0 state, a kick-start circuit is engaged for a few milliseconds. The kick-start circuit ensures self-starting for a properly-designed crystal oscillator

**NOTE**

Whenever C2 is 1, both bits C1 and C0 must be 1, also.

To minimize standby supply current, the voltage multiplier may be shut down (by bits R'19, R'18, and R'17 being all zeroes). If this is the case and the voltage multiplier feature is being used, the user must allow sufficient time for the phase/frequency detector supply voltage to pump up when the multiplier is brought out of standby. This “pump up” time is dependent on the C<sub>mult</sub> capacitor size. Pump current is approximately 100  $\mu$ A. During the pump up time, either the PLL standby bits C1 and C2 must be 1 or the phase/frequency detector float bits C3 and C4 must be 1.

**PLL Stby (C1)**

When set to 1, this bit places the main PLL in the standby mode for reduced power consumption. PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub> are forced to the floating state, the N and R counters are inhibited from counting, the main loop's input amp is shut off, the Rx current is inhibited, and the main phase/frequency detector is shut off. The reference oscillator circuit is still active and independently controlled by bit C2.

When this bit is programmed to 0, the main PLL is taken out of standby in two steps. First, the input amplifier is activated, all counters are enabled, and the Rx current is no longer inhibited. Any f<sub>R</sub> and f<sub>Y</sub> signals are inhibited from toggling the phase/frequency detectors and lock detector at this time. Second, when the f<sub>R</sub> pulse occurs, the N counter is loaded, and the phase/frequency and lock detectors are initialized via both flip-flops being reset. Immediately after the load, the N and R counters begin counting down together. At this point, the f<sub>R</sub> and f<sub>Y</sub> pulses are enabled to the phase

## MC145225 MC145230

and lock detectors, and the phase/frequency detector output is enabled to issue an error correction pulse on the next  $f_R$  and  $f_V$  pulses. (Patent issued on this method.)

During standby, data is retained in all registers and any register may be accessed. When setting or clearing the PLL Stby bit, other bits in the C register may be changed simultaneously.

### PLL' Stby (C0)

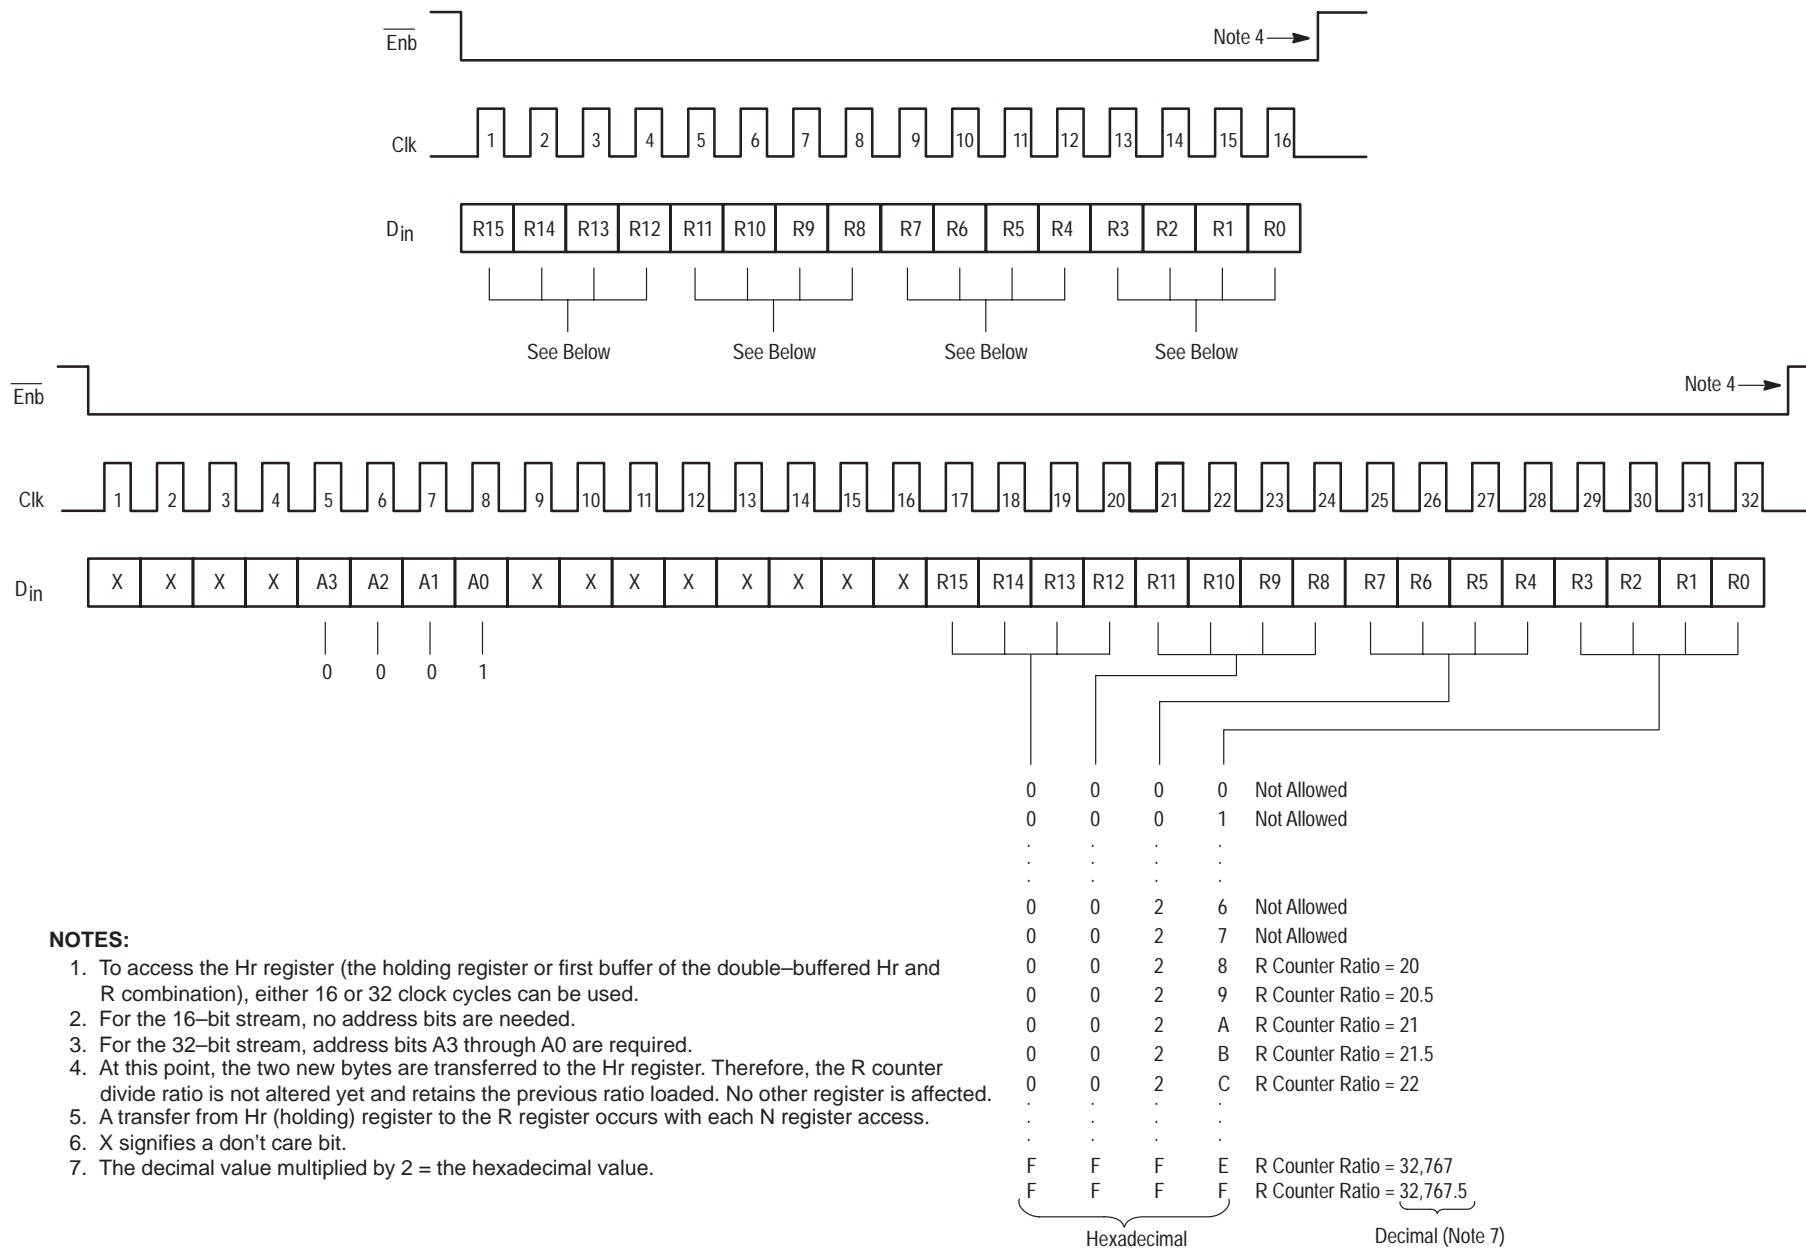

When set to 1, this bit places the PLL' section of the chip, which includes the on-chip  $f_{in}'$  input amp, in the standby mode for reduced power consumption.  $PD_{out}'$  is forced to the floating state. The R' and N' counters are inhibited from counting and placed in the low-current mode. The exception is the R' counter's prescaler when the Mode pin is low. The R' counter's prescaler remains active along with the  $f_{out}$  and  $\overline{f_{out}}$  pins when PLL' is placed in standby (Mode pin = low). When the Mode pin is low, the  $f_{out}$  pin,  $\overline{f_{out}}$  pin, and R'

counter's prescaler are shut down only when Osc Stby bit C2 is set to 1.

When C0 is reset to 0, PLL' is taken out of standby in two steps. All PLL' counters and the input amp are enabled. Any  $f_R'$  and  $f_V'$  signals are inhibited from toggling the associated phase/frequency detector at this time. Second, when the  $f_R'$  pulse occurs, the N' counter is loaded and the phase/frequency detector is initialized via both flip-flops being reset. Immediately after the load, the N' and R' counters begin counting down together. At this point, the  $f_R'$  and  $f_V'$  pulses are enabled to the phase and lock detectors, and the phase/frequency detector output is enabled to issue an error correction pulse on the next  $f_R'$  and  $f_V'$  pulses. (Patent issued on this method.)

During standby, data is retained in all registers, and any register may be accessed. When setting or clearing the PLL' Stby bit, other bits in the C register may be changed simultaneously.

Figure 14. Hr Register Access and Formats

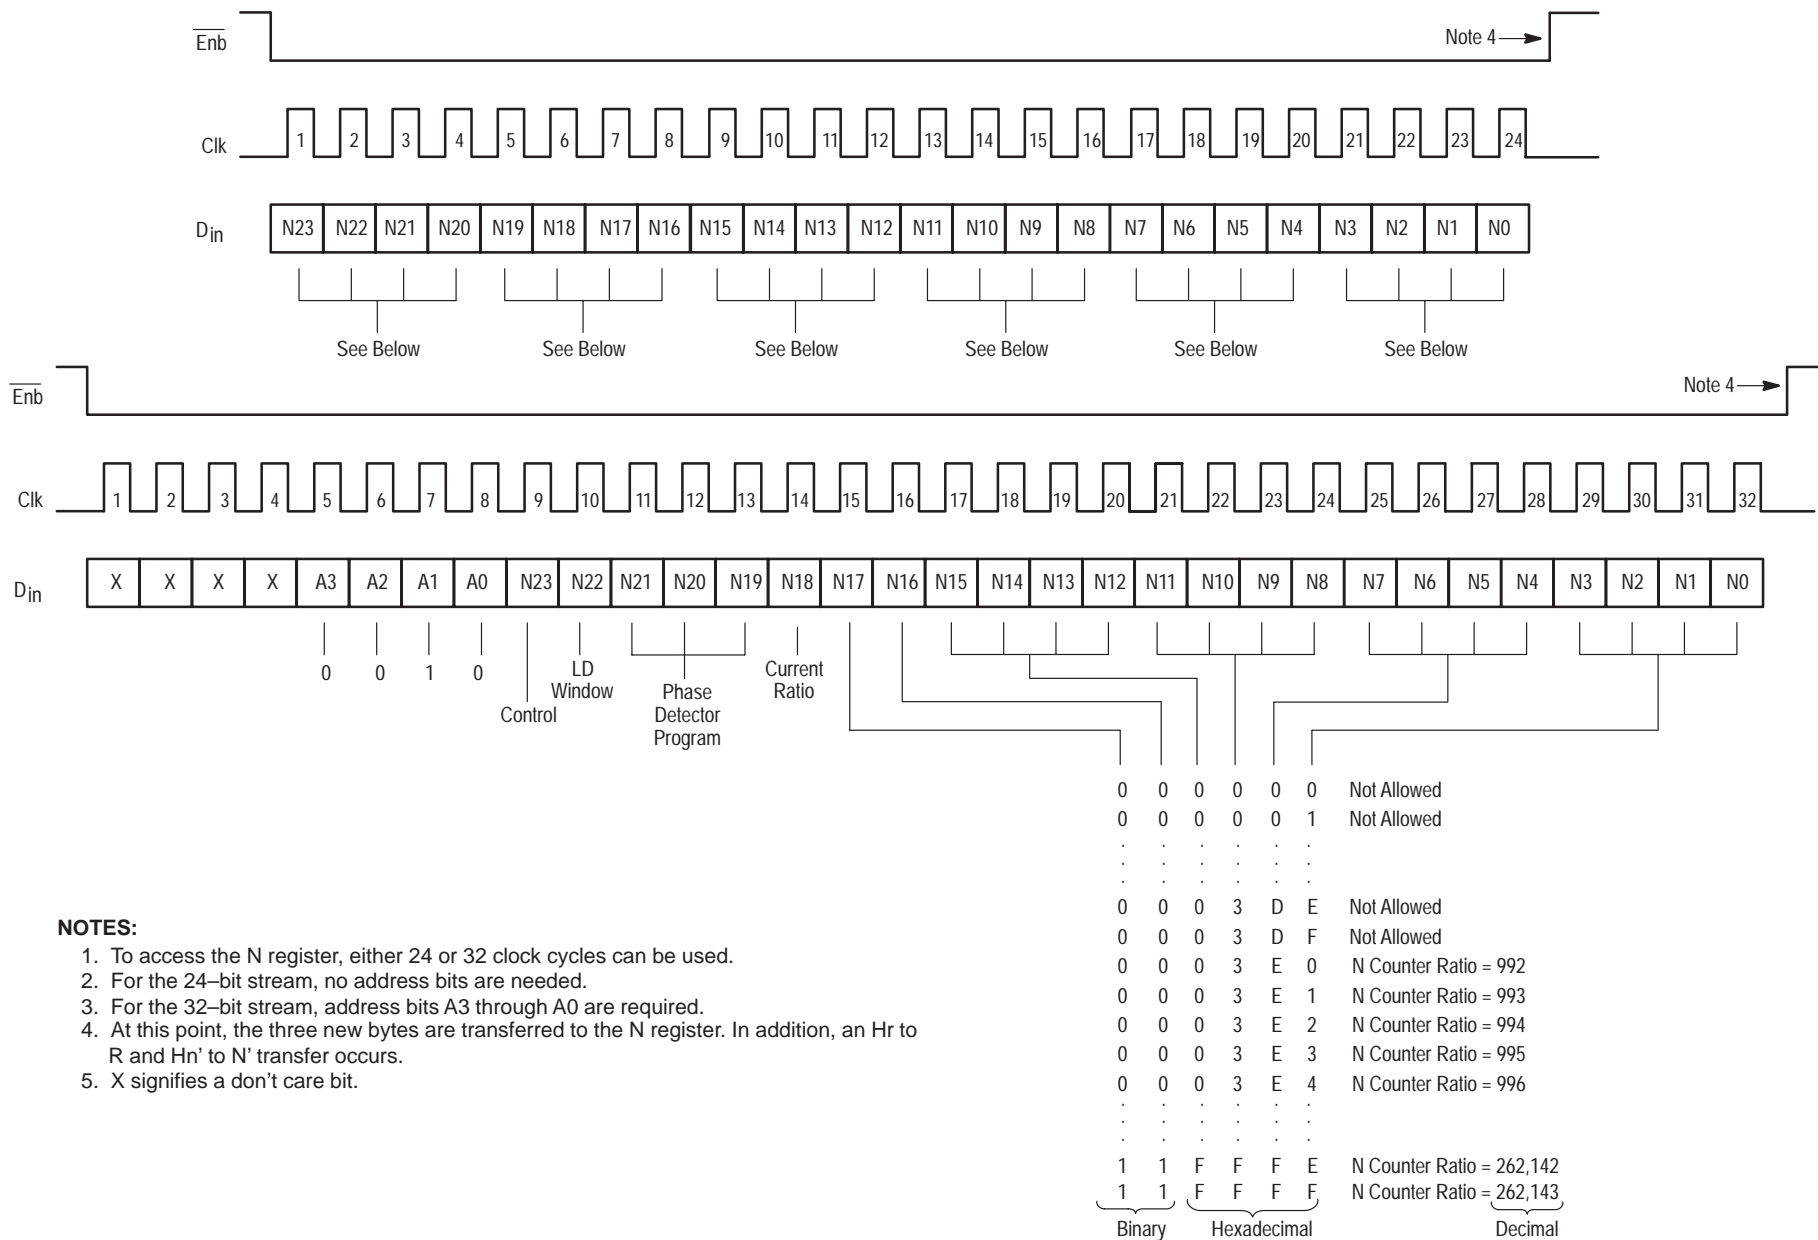

NOTES:

- To access the Hr register (the holding register or first buffer of the double-buffered Hr and R combination), either 16 or 32 clock cycles can be used.
- For the 16-bit stream, no address bits are needed.
- For the 32-bit stream, address bits A3 through A0 are required.
- At this point, the two new bytes are transferred to the Hr register. Therefore, the R counter divide ratio is not altered yet and retains the previous ratio loaded. No other register is affected.
- A transfer from Hr (holding) register to the R register occurs with each N register access.
- X signifies a don't care bit.
- The decimal value multiplied by 2 = the hexadecimal value.

Figure 15. N Register Access and Formats

NOTES:

1. To access the N register, either 24 or 32 clock cycles can be used.
2. For the 24-bit stream, no address bits are needed.
3. For the 32-bit stream, address bits A3 through A0 are required.
4. At this point, the three new bytes are transferred to the N register. In addition, an Hr to R and Hn' to N' transfer occurs.
5. X signifies a don't care bit.

**N REGISTER BITS**

See Figure 15 for N register access and serial data formats.

**Control (N23)**

When the Mode pin is low, Control bit N23 determines the divide ratio of the auxiliary divider which feeds the buffers for the  $f_{out}$  and  $\overline{f_{out}}$  pins. See Table 14 for the overall ratio between  $Osc_e$  and  $f_{out}/\overline{f_{out}}$ .

When the Mode pin is high, N23 must be programmed to 1.

**Table 14.  $Osc_e$  to  $f_{out}$  Frequency Ratio, Mode = Low**

N23	R'1	R'0	$Osc_e$ to $f_{out}$ Frequency Ratio
0	0	0	10:1
0	0	1	12.5:1
0	1	0	12.5:1
0	1	1	12.5:1
1	0	0	8:1
1	0	1	10:1
1	1	0	10:1
1	1	1	10:1

**LD Window (N22)**

Bit N22 determines the lock detect window for the main loop. Refer to Table 15 and Figure 19.

**Table 15. Lock Detect Window**

N22	LD Window (Approximated)
0	32 $Osc_e$ periods
1	128 $Osc_e$ periods

**Phase Detector Program (N21, N20, N19)**

These bits control which phase detector outputs are active for the main loop. These bits also control the timer interval when adapt is utilized for the main loop. See Table 16.

**Table 16. Main Phase Detector Control**

N21	N20	N19	Result
0	0	0	Both PD <sub>out-Hi</sub> and PD <sub>out-Lo</sub> floating
0	0	1	PD <sub>out-Hi</sub> floating, PD <sub>out-Lo</sub> enabled
0	1	0	PD <sub>out-Hi</sub> enabled, PD <sub>out-Lo</sub> floating
0	1	1	Both PD <sub>out-Hi</sub> and PD <sub>out-Lo</sub> enabled
1	0	0	PD <sub>out-Hi</sub> enabled and PD <sub>out-Lo</sub> floating for 16 $f_R$ cycles, then PD <sub>out-Hi</sub> floating and PD <sub>out-Lo</sub> enabled
1	0	1	PD <sub>out-Hi</sub> enabled and PD <sub>out-Lo</sub> floating for 32 $f_R$ cycles, then PD <sub>out-Hi</sub> floating and PD <sub>out-Lo</sub> enabled
1	1	0	PD <sub>out-Hi</sub> enabled and PD <sub>out-Lo</sub> floating for 64 $f_R$ cycles, then PD <sub>out-Hi</sub> floating and PD <sub>out-Lo</sub> enabled
1	1	1	PD <sub>out-Hi</sub> enabled and PD <sub>out-Lo</sub> floating for 128 $f_R$ cycles, then PD <sub>out-Hi</sub> floating and PD <sub>out-Lo</sub> enabled

**Current Ratio (N18)**

This bit allows for MCU control of the PD<sub>out-Hi</sub> to PD<sub>out-Lo</sub> current (or gain) ratio on the main loop phase/frequency detector outputs. See Table 17.

**Table 17. PD<sub>out-Hi</sub> to PD<sub>out-Lo</sub> Current Ratio**

N18	PD <sub>out-Hi</sub> to PD <sub>out-Lo</sub> Current Ratio	PD <sub>out-Hi</sub> Current $C_{mult}$ Pin = 5 V (Nominal)	PD <sub>out-Lo</sub> Current $C_{mult}$ Pin = 5 V (Nominal)
0	4:1	4.4 mA	1.1 mA
1	8:1	4.4 mA	0.55 mA

**N Counter Divide Ratio (N17 to N0)**

These bits control the N Counter divide ratio or loop multiplying factor. The minimum allowed value is 992. The maximum value is 262,143. For ease of programming, binary representation is used. For example, if a divide ratio of 1000 is needed, the 1000 in decimal is converted to binary 00 0000 0011 1110 1000 and is loaded into the device for N17 to N0. See Figure 15.

Hexadecimal				Decimal (Note 4)

**NOTES:**

1. To access the R' register, 32 clock cycles must be used.
2. Address bits A3 through A0 are required.
3. At this point, the three new bytes are transferred to the R' register. No other register is affected.
4. The decimal value multiplied by 2 = the hexadecimal value. Counter divide ratios shown apply when the Mode pin is tied high. For ratios when the Mode pin is tied low, see Table 21.
5. X signifies a don't care bit.

## MC145225 MC145230

### R' REGISTER BITS

See Figure 16 for R' register access and serial data format.

### Y Coefficient (R'23 and R'22)

These bits are programmed per Table 18. Note that for the MC145181, the bits are always programmed as 00. For compatibility, the other combinations are reserved for use with the MC145225 and MC145230.

**Table 18. Y Coefficient**

R'23	R'22	Maximum Allowed Frequency at $f_{in}$ Pin
0	0	550 MHz
0	1	1.2 GHz
1	0	2.2 GHz
1	1	(not used)

### Output A Function (R'21 and R'20)

These bits control the function of the Output A pin per Table 19. When selected as a general-purpose output, bit C7 controls the state of the pin. The signals  $f_R$  and  $f_{R'}$  are the outputs of the R and R' counters, respectively. The selection as a detector pulse is a test feature.

**Table 19. Output A Function Selection**

R'21	R'20	Function Selected for Output A
0	0	General-Purpose Output
0	1	$f_R$
1	0	$f_{R'}$
1	1	Phase/Frequency Detector Pulse from both loops

### V-Mult Control (R'19, R'18, R'17)

These bits control the voltage multiplier per Table 20. When the multiplier is in the active state, the bits determine the voltage multiplier's refresh rate of the capacitor tied to the  $C_{mult}$  pin.

When active, the bits should be programmed for the lowest possible maximum frequency shown in the table. This

ensures that the voltage multiplier is operating at optimum efficiency. For example, for a system utilizing a 16.8 MHz reference, bits R'19, R'18, and R'17 should be programmed as 001 if the user desires to use the voltage multiplier. If the user does not want to use the multiplier, the bits should be programmed as 000. In the latter case, only a 0.1  $\mu$ F bypass capacitor is needed at the  $C_{mult}$  pin and an external phase/frequency detector supply voltage of 3.6 to 5.25 V must be provided to the  $C_{mult}$  pin.

**Table 20. Voltage Multiplier Control**

R'19	R'18	R'17	Multiplier State	Maximum Allowed Frequency at $Osc_e$ Pin
0	0	0	Inactive	80 MHz
0	0	1	Active	20 MHz
0	1	0	Active	40 MHz
0	1	1	Active	80 MHz
1	X	X	—	(for factory evaluation)

### Test/Rst (R'16)

This bit must be programmed to 0 by the user.

### R' Counter Divide Ratio (R'15 to R'0)

These bits control the R' counter divide ratio. Thus, these bits determine the secondary loop's minimum step size. This step size is the same as the phase/frequency detector's operating frequency which must not exceed 600 kHz.

With the Mode pin tied high, the minimum allowed value is 20. The maximum value is 32,767.5. For ease of programming, binary representation is used. However, the binary value must be multiplied by 2. For example, if a divide ratio of 1000 is needed, the 1000 in decimal is converted to binary 0000 0011 1110 1000. This value is multiplied by 2 and becomes 0000 0111 1101 0000 and is loaded into the device for R'15 to R'0. See Figure 16.

With the Mode pin tied low, Table 21 shows the divide ratios available. There are two formulas for the divide ratio when Mode is low.

If R'1 R'0 are 00: R' Ratio = (Value of R'15 to R'2)  $\times$  2.

If R'1 R'0 are 01, 10, 11: R' Ratio = (Value of R'15 to R'2)  $\times$  2.5.

\* Divide ratios with the Mode pin tied high are shown in Figure 16.

Figure 17. Hn' Register Access and Format

NOTES:

- To access the Hn' register (the holding register or first buffer of the double-buffered Hn' and N' combination), 32 clock cycles must be used.
- Address bits A3 through A0 are required.
- At this point, the two new bytes are transferred to the Hn' register. Therefore, the N' counter divide ratio is not altered yet and retains the previous ratio loaded. No other register is affected.
- A transfer from the Hn' (holding) register to the N' register occurs with each N register access.
- X signifies a don't care bit.

Figure 18. D Register Access and Format

NOTES:

1. To access the D Register, 32 clock cycles are used.
2. Address bits A3 through A0 are required.
3. At this point, the two new bytes are transferred to the D register. No other register is affected.
4. Low-power standby state.
5. X signifies a don't care bit.

# MC145225 MC145230

Figure 19. Lock Detector Operation

**NOTES:**

1. Illustration shown is for the main loop and applies when the secondary loop is either phase locked or in standby. The actual detector outputs for each loop are ANDed together at the LD pin.
2. The secondary loop is similar to the above illustration.
3. The approximate lock detect window for the main loop is either 64 or 256  $Osc_e$  cycles and is programmable via bit N22. The approximate window for the secondary loop is 64  $Osc_e$  cycles and is not programmable.
4. The LD output is low whenever the phase difference is more than the lock detect window.
5. The LD output is high whenever the phase difference is less than the lock detect window and continues to be less than the window for 3  $f_R$  periods or more.

**LOCK DETECTOR OUTPUT CONDITIONS**

$f_R$ versus $f_V$ Relation	Lock Detector Output	Microcontroller Action
Frequency is the same with phase inside the LD window	Static high level output	Senses high level and no edges, therefore loop is locked
Frequency is the same with phase outside the LD window	Static low level output	Senses low level, therefore loop is unlocked
Frequency is slightly different, thus phase is changing	Dynamic "chattering" output, output has transitions	Senses edges, therefore loop is unlocked
Frequency is grossly different	Static low level output	Senses low level, therefore loop is unlocked

**NOTE:** For simplicity, this table applies to the main loop. The secondary loop is similar. The detector outputs feed an AND gate whose output is the LD pin.

Figure 20. PD<sub>Out-Hi</sub> and PD<sub>Out-Lo</sub> Detector Output Characteristics

\*At this point, when both  $f_R$  and  $f_V$  are in phase, the output source and sink circuits are turned on for a short interval.

**NOTES:**

1. The detector generates error pulses during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low-pass filter capacitor.
2. Waveform shown applies when the  $f_{Out}/Pol$  pin is low and the Mode pin is high.
3. When the  $f_{Out}/Pol$  pin is high and Mode is high, the PD<sub>Out-Hi</sub> and PD<sub>Out-Lo</sub> waveform is inverted.
4. The waveform shown is also the default when the Mode pin is low.

Figure 21. PD<sub>Out'</sub> Detector Output Characteristics

\*At this point, when both  $f_{R'}$  and  $f_{V'}$  are in phase, the output source and sink circuits are turned on for a short interval.

**NOTES:**

1. The detector generates error pulses during out-of-lock conditions. When locked in phase and frequency, the output is high impedance and the voltage at that pin is determined by the low-pass filter capacitor.
2. Waveform shown applies when the  $f_{Out'}/Pol'$  pin is low and the Mode pin is high.
3. When the  $f_{Out'}/Pol'$  pin is high and Mode is high, the PD<sub>Out'</sub> waveform is inverted.
4. The waveform shown is also the default when the Mode pin is low.

7. APPLICATIONS INFORMATION

7A. CRYSTAL OSCILLATOR CONSIDERATIONS

The oscillator/reference circuit may be connected to operate in either of two configurations. With the Mode pin placed “high” and bit C6 programmed to 1, the oscillator/reference circuit of the MC145181 will accept an external reference input. The external reference signal should be capacitive, connected to Osc<sub>e</sub> with Osc<sub>b</sub> left floating. Commercially available temperature compensated crystal oscillators (TCXOs) or crystal-controlled data clock oscillators provide a very stable reference frequency. For additional information about TCXOs and data clock oscillators, please consult the Electronic Engineers Master Catalog, internet web page, or similar publication/service.

The on-chip Colpitts reference oscillator can be selected by either tying the Mode pin low or by programming the C6 bit to zero when Mode is high. The oscillator may be operated in either the fundamental mode, as show by Figure 22, or as an overtone oscillator. The “kick start” feature ensures reduced “stalling” of hard-starting crystals.

Crystal Resonators

The equivalent circuit of a crystal resonator most commonly used is shown in Figure 23. The crystal itself is a specially cut (usually AT for overtone operation) block of quartz. The dimensions, (shape, thickness, length, and width) determine the operating characteristics of the crystal. When deformed and allowed to return naturally to its resting shape, it is observed to oscillate. This oscillation has the typical characteristics of a damped oscillation and an equivalent electrical signal can be found on the surface of the crystal. In addition, if an equivalent electrical signal is applied to the crystal, it will be observed to oscillate. The equivalent values for R<sub>S</sub>, L<sub>S</sub>, C<sub>S</sub>, and C<sub>O</sub> can be used to predict the operation of the crystal when used as an electronic oscillator.

Due to the series/parallel arrangement of the equivalent components, the crystal exhibits two resonances. The first, sometimes just called resonance, is the series resonance of the R<sub>S</sub>, C<sub>S</sub>, L<sub>S</sub> branch. The other, sometimes called the anti-resonance, is the parallel resonance including C<sub>O</sub>. For the series resonance the formula is

$$f_s = \frac{1}{2\pi \sqrt{L_S C_S}}$$

For parallel resonance, the formula is

$$f_p = \frac{1}{2\pi \sqrt{\frac{L_S C_S C_O}{C_O + C_S}}}$$

As can be seen from this equation, the anti-resonant frequency is higher than the series resonant frequency. The ratio between the resonant and anti-resonant frequency can be found using the formula

$$\frac{\Delta f}{f} = \frac{C_S}{2(C_O + C_S)}$$

where

$$\Delta f = |f_s - f_p|$$

and

$$f = \frac{f_s + f_p}{2}$$

By exploiting this characteristic, the crystal oscillator frequency can be tuned slightly. If a capacitor is connected in series with the crystal operating in the resonance mode, the frequency will shift upward. If a capacitance is added in parallel with a crystal operating in an anti-resonant mode, the frequency will be shifted down.

Figure 22. Fundamental Mode Oscillator Circuit

Figure 23. Crystal Resonator Equivalent Circuit

NOTE: Values are supplied by crystal manufacturer (parallel resonant crystal).

Because of the acoustic properties of the crystal resonator, the crystal “tank” responds to energy not only at its fundamental frequency, but also at specific multiples of the fundamental frequency. In the same manner that a shorted or open transmission line responds to multiples of the fundamental frequency, the crystal “tank” responds similarly. A shorted half-wave transmission line (or closed acoustic chamber) will not only resonate at its fundamental frequency, but also at odd multiples of the fundamental. These are called the overtones of the crystal and represent frequencies at which the crystal can be made to oscillate. The equivalent circuit of an overtone crystal is shown in Figure 24.

The components for the appropriate overtone are represented by 1, 3, and 5. The fundamental components are represented by 1, and those of importance for the third and fifth overtones, by 3 and 5.

**Fundamental Mode**

The equivalent circuit for the Colpitts oscillator operating in the fundamental mode is shown in Figure 25.

C3 is selected to provide a small reduction in the inductive property of the crystal. In this manner, the frequency of the oscillator can be “pulled” slightly. The biasing combination of

Figure 24. Overtone Crystal Equivalent Circuit

M1R1 and M2R2 provide the ability to start operation with a higher than normal operating current to stimulate crystal activity. This “kick start” current is nominally four times the normal current. An internal counter times the application of the “kick start” and returns the current to normal after the time out period.

The mutual conductance (transconductance) of the transistor Q1 is useful in determining the conditions necessary for oscillation. The nominal value for the transconductance is found from the formula

$$g_m = \frac{I_e}{26}$$

where I<sub>e</sub> is the emitter current in mA.

The operation of the oscillator can be described using the concept of “negative resistance”. In a normal tuned circuit, any excitation tends to be dissipated by the resistance of the circuit and oscillation dies out. The resistive part of the crystal along with the resistance of the wiring and the internal resistance of C1, C2, and C3, make up this “damping” resistance. Some form of energy must be fed back into the circuit to sustain oscillation. This is the purpose of the amplifier.

Figure 25. Fundamental Mode Colpitts Oscillator Equivalent Circuit

If we define the damping as resistive, we can define the opposite or regenerative property as negative resistance. Figure 26 shows the basic circuit of the Colpitts oscillator. C3 has been combined with the crystal elements for simplicity. For the circuit to oscillate, there must be at least as much "negative resistance" (regeneration) as there is resistance (damping). We can define this by deriving the input impedance for the amplifier.

Figure 26. Colpitts Oscillator Basic Circuit

If a driving signal is defined as  $V_{in}$ , the resultant current that flows can be identified as  $I_{in}$ . The relationship of  $V_{in}$  to  $I_{in}$  is

$$V_{in} = I_{in} (Z_{C1} + Z_{C2}) - I_b (Z_{C2} - \beta Z_{C1})$$

and

$$0 = I_{in} (Z_{C2}) + I_b (Z_{C2} + r_b)$$

where  $I_b$  is the base current of transistor Q1. Solving the two equations and assuming  $Z_{C2} \ll r_b$ , the input impedance can be expressed as

$$Z_{in} \sim \frac{-gm}{\omega^2 C1 C2} + \frac{1}{j\omega \left( \frac{C1 C2}{C1 + C2} \right)}$$

where  $\omega = 2\pi f$ . This is equivalent to the series combination of a real part whose value is

$$REAL = \frac{-gm}{\omega^2 C1 C2}$$

and the imaginary part whose value is

$$IMAG = \frac{1}{j\omega \left( \frac{C1 C2}{C1 + C2} \right)}$$

To sustain oscillation, the amplifier must generate a "negative resistance" equal or greater than the REAL part of the above equation and opposite in polarity.

$$R_{neg} = \frac{-gm}{\omega^2 C1 C2}$$

As long as the relation

$$-R_{neg} = -SUM (R_s + R_{st} + R_{C1} + R_{C2} + R_{C3}) ,$$

the circuit will oscillate and the frequency of oscillation will be defined as

$$f_o = \frac{1}{2\pi \sqrt{L_s (C1 \parallel C2 \parallel C3)}}$$

where C3 is the series frequency adjusting capacitor.

In determining values for C1, C2, and C3, two limits are considered. At one end is the relationship of C3 to C2 and C1. If C3 is made 0 or the reactance of C3 is small compared to the reactance of C1 and C2, no adjustment of the crystal frequency is possible. The other limit is the relationship

$$gm Z_{C1} Z_{C2} > R_{sum}$$

where  $R_{sum}$  is the sum of resistances in the resonant loop. Since this equation must be true for the circuit to oscillate, it is obvious that as the values of C1 and C2 are increased, the series resistances must be reduced and/or gm increased. Since gm is a function of device current and there is a physical limit on how small  $R_{sum}$  can be made, at some point oscillation can no longer be sustained.

Normally, it is desirable to choose the "negative resistance" to be several times greater than the "damping" resistance to ensure stable operation. A factor of four or five is a good "rule of thumb" choice.

To determine crystal power, the equivalent circuit shown in Figure 27 can be used. In this case, we are addressing a condition where the transistor amplifier is operating at the limit of class A; that is, the device is just at cutoff during the peak negative excursions. At this point,

$$R_e = gm X_{C1} X_{C2}$$

if the amplitude is constant and the oscillator is stable. For this to occur, the sum of all resistances in the resonant loop will be equal to  $R_e$ , where  $R_e$  represents the effective resistance of  $I_1$ . This can be written as

$$R_{sum} = R_s + R_{st} = R_e$$

where  $R_s$  is the crystal resistance and  $R_{st}$  is the additional distributed resistances within the resonant loop. At the point where the transistor enters cutoff we have the equation

$$-I_{in} = \frac{v1 + v2}{X_{Is} + R_e} = \frac{(I_{in} - I_b) Z_{C2} + (I_{in} + \beta I_b) Z_{C1}}{X_{Is} + R_e}$$

$\beta$  = current gain of the transistor. Rewriting:

$$I_{in} = \frac{I_b (Z_{C2} - \beta Z_{C1})}{Z_{C1} + Z_{C2} + X_{Is} + R_e}$$

For oscillation to occur, we must have

$$Z_{C1} + Z_{C2} + X_{Is} \sim 0 .$$

If we assume  $\beta Z_{C1}$  is normally much greater than  $Z_{C2}$  then

$$I_{in} \sim \frac{-I_e Z_{C1}}{R_e}$$

For the condition we have specified,

$$I_e(\text{bias}) + I_e(\text{instantaneous ac}) = 0$$

the transistor is just cutting off and the peak current,  $I_{in}$  is equal to the bias current. The peak input current is represented as

$$I_{in}(\text{peak}) = \frac{I_e |Z_{C1}|}{R_e}$$

The power dissipation of the series resistances in the resonant loop can be written as

$$P = \frac{I_{in}(\text{peak})^2 R}{2} = \frac{(I_e |Z_{C1}|)^2}{2 R_{sum}}$$

where  $R_{sum} = R_e$ .

The power dissipation for the crystal itself becomes

$$P_{crystal} = \frac{(I_e |Z_{C1}|)^2}{2 R_s}$$

Figure 27. Equivalent Circuit for Crystal Power Estimation

**Overtone Operation**

For overtone operation, the circuit is modified by the addition of an inductor, L1; and a series capacitor, C4. C4 is inserted as a dc blocking capacitor whose capacitance is chosen sufficiently large so that its reactance can be ignored. This circuit is shown in Figure 28.

For oscillation to occur at the overtone frequency, the condition

$$gm Z_{C1} Z_{C2} > R_s$$

must exist.

$Z_{C1}$  represents the impedance across C1 and can be defined as

$$Z_{C1} = jX_{C1} || (R_{l1} + jX_{l1})$$

where  $R_{l1}$  is the dc resistance of the inductor L1.

For overtone operation, this must occur at the desired harmonic. For example, if the crystal is chosen to oscillate at the third overtone, C1 and C2 must be chosen so that the above condition exists for  $Z_{C1}$  and  $Z_{C2}$  at the third harmonic of the fundamental frequency for the crystal. In addition, care must be taken that the “negative resistance” of the amplifier is not sufficient at the fundamental frequency to induce oscillation at the fundamental frequency. It may be necessary to add additional filtering to reduce the gain of the amplifier at the fundamental frequency. The key to achieving stable overtone oscillator operation is ensuring the existence of the above condition at the desired overtone while ensuring its failure at all other frequencies.

L1 and C1 are chosen so that

$$\frac{1}{2\pi \sqrt{L_1 C_1}} > F_f$$

where  $F_f$  is the fundamental frequency of the crystal resonator. If L1 and C1 are chosen to be net capacitive at the desired overtone frequency and if the condition

$$gm Z_{C1} Z_{C2} > R_s$$

is true only at the desired overtone frequency, the oscillator will oscillate at the frequency of the overtone. Normally, L1 and C1 are not chosen to be resonant at the overtone frequency but at a lower frequency to ensure that the parallel

combination of L1 and C1 is capacitive at the overtone frequency and inductive at the fundamental frequency.

$$F_f < \frac{1}{2\pi \sqrt{L_1 C_1}} < F_o$$

The net inductance of the rest of the resonant loop then balances this capacitance at the overtone frequency.

$$\frac{1}{\frac{1}{X_{lS} - X_{cS}} - \frac{1}{X_{c0}}} + X_{l2} + X_{l(\text{stray})} - X_{c3} + \frac{1}{\frac{1}{X_{l1}} - \frac{1}{X_{c1}}} = 0$$

L2 and C3 are chosen to provide the desired adjustment to the resonant overtone frequency. This is normally computed by calculating the expected ppm change at the resonant frequency and using this to define the value of the reactance necessary to produce this change.

$$\Delta F_f (\text{ppm}) = \frac{X (\text{of } L_2 \text{ and } C_3)}{Z (\text{crystal at resonance})}$$

$$\Delta F_f (\text{ppm}) = X(\text{of } L_2 \text{ and } C_3)/Z(\text{crystal at resonance})$$

The values needed for this calculation can be derived from the value of the fundamental frequency and  $C_o$ . If  $C_o$  is known or can be measured,  $C_s$  is defined as

$$C_s = \frac{C_o}{200}$$

for an AT cut crystal.

The fundamental frequency can be used to calculate the value for  $L_s$  using either the series resonant or parallel resonant formulas given earlier. Since the Q of the crystal,

$$Q = \frac{X}{R}$$

is usually sufficiently large at the resonant frequency so that

$$R_s \ll Z(\text{crystal})$$

## MC145225 MC145230

$R_S$  can be ignored. The value for  $C_3$  and  $L_2$  are chosen so that

$$X_{C3} = X_{L2}$$

when  $C_3$  is adjusted to approximately half its maximum capacitance. At this setting, the combination produces a zero change in the overtone frequency. If  $C_3$  is then chosen so that  $X_{C3}$  at minimum capacitance is

$$[X_{C3(\max)}] - X_{L2} \geq \Delta F_f (\text{ppm}) Z(\text{crystal})$$

and  $L_2$  is approximately

$$X_{L2} = \frac{X_{C3(\max)}}{2}$$

then

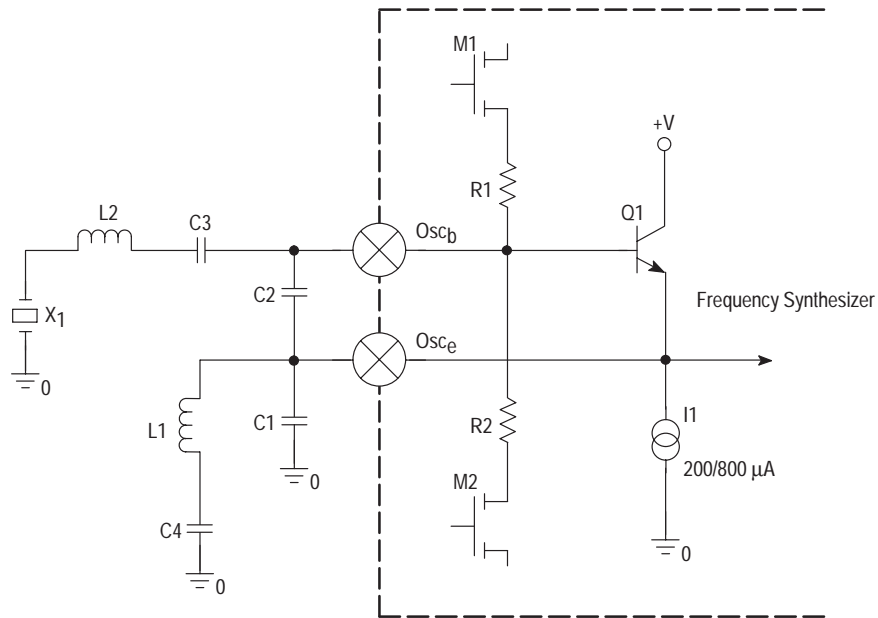

$$X_{C3(\max)} \geq 2[\Delta F_f (\text{ppm})] Z(\text{crystal})$$

and

$$X_{C3(\min)} = \frac{X_{C3(\max)}}{4}$$

This results in an adjustable change in the operating frequency of  $+\Delta F_f (\text{ppm})$  and  $-\Delta F_f (\text{ppm})/2$ . If ratios nearer to 1:1 are used for  $X_{C3(\max)}$  and  $X_{L2}$ , the tuning range will be skewed with a wider  $-\Delta F_f (\text{ppm})$  but at the expense of less adjustability over the  $+\Delta F_f (\text{ppm})$  range.

**Figure 28. Colpitts Oscillator Configured for Overtone Operation**

**7B. MAIN LOOP FILTER DESIGN — CONVENTIONAL**

The current output of the charge pump allows the loop filter to be realized without the need of any active components. The preferred topology for the filter is illustrated in Figure 29.

The  $R_O/C_O$  components realize the primary loop filter.  $C_a$  is added to the loop filter to provide for reference sideband suppression. If additional suppression is needed, the  $R_x/C_x$  realizes an additional filter. In most applications, this will not be necessary. If all components are used, this results in a fourth order PLL, which makes analysis difficult. To simplify this, the loop design will be treated as a second order loop ( $R_O/C_O$ ), and additional guidelines are provided to minimize the influence of the other components. If more rigorous analysis is needed, mathematical/system simulation tools should be used.

Component	Guideline
$C_a$	$<0.1 \times C_O$
$R_x$	$>10 \times R_O$
$C_x$	$<0.1 \times C_O$

The focus of the design effort is to determine what the loop's natural frequency,  $\omega_O$ , should be. This is determined by  $R_O$ ,  $C_O$ ,  $K_P$ ,  $K_V$ , and  $N_t$ . Because  $K_P$ ,  $K_V$ , and  $N_t$  are given, it is only necessary to calculate values for  $R_O$  and  $C_O$ . There are three considerations in selecting the loop bandwidth:

1. Maximum loop bandwidth for minimum tuning speed.
2. Optimum loop bandwidth for best phase noise performance.
3. Minimum loop bandwidth for greatest reference sideband suppression.

Usually a compromise is struck between these three cases, however, for a fixed frequency application, minimizing the tuning speed is not a critical parameter.

To specify the loop bandwidth for optimal phase noise performance, an understanding of the sources of phase noise in the system and the effect of the loop filter on them is required. There are three major sources of phase noise in the phase-locked loop — the crystal reference, the VCO, and

the loop contribution. The loop filter acts as a low-pass filter to the crystal reference and the loop contribution. The loop filter acts as a high-pass filter to the VCO with an in-band gain equal to unity. The loop contribution includes the PLL IC, as well as noise in the system; supply noise, switching noise, etc. For this example, a loop contribution of 15 dB has been selected.

The crystal reference and the VCO are characterized as high-order  $1/f$  noise sources. Graphical analysis is used to determine the optimum loop bandwidth. It is necessary to have noise plots from the manufacturers of both devices. This method provides a straightforward approximation suitable for quickly estimating the optimal bandwidth. The loop contribution is characterized as white-noise or low-order  $1/f$  noise, given in the form of a noise factor which combines all the noise effects into a single value. The phase noise of the crystal reference is increased by the noise factor of the PLL IC and related circuitry. It is further increased by the total divide-by- $N$  ratio of the loop. This is illustrated in Figure 30. The point at which the VCO phase noise crosses the amplified phase noise of the crystal reference is the point of the optimum loop bandwidth. In the example of Figure 30, the optimum bandwidth is approximately 15 kHz.

To simplify analysis further, a damping factor of 1 will be selected. The normalized closed loop response is illustrated in Figure 31 where the loop bandwidth is 2.5 times the loop natural frequency (the loop natural frequency is the frequency at which the loop would oscillate if it were unstable). Therefore, the optimum loop bandwidth is  $15 \text{ kHz}/2.5$  or 6.0 kHz (37.7 krads) with a damping coefficient,  $\zeta \sim 1$ .  $T(s)$  is the transfer function of the loop filter.

where

$$N_t = \text{Total PLL Divide Ratio} - 8 \times N$$

where ( $N = 25 \dots 40$ ),

$$K_V = \text{VCO Gain} - 2\pi \text{ Hz/V},$$

$$K_P = \text{Phase Detector/Charge Pump Gain} - A$$

$$= (|I_{OH}| + |I_{OL}|) / 4\pi.$$

Technically,  $K_V$  and  $K_P$  should be expressed in radian units [ $K_V$  (rad/V),  $K_P$  (A/rad)]. Since the component design equation contains the  $K_V \times K_P$  term, the  $2\pi$  cancels and the value can be expressed as AHz/V (amp hertz per volt).

**Figure 29. Loop Filter**

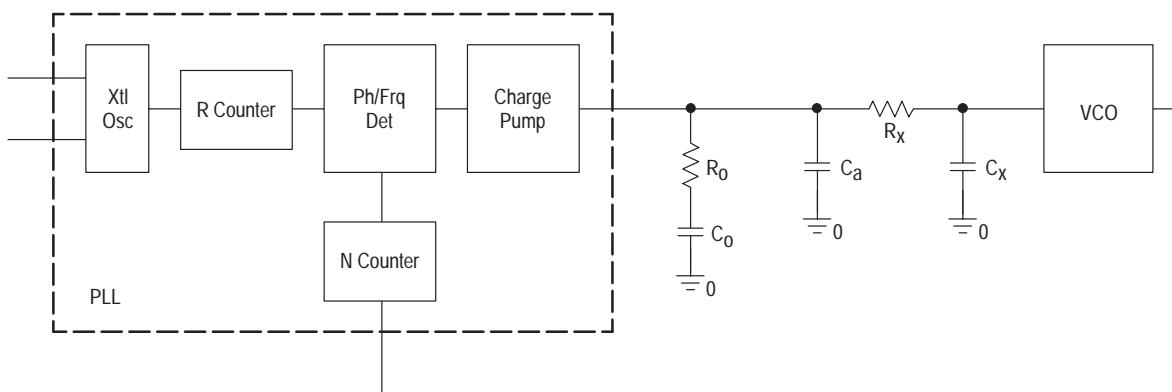

Figure 30. Graphical Analysis of Optimum Bandwidth

In summary, follow the steps given below:

- Step 1: Plot the phase noise of crystal reference and the VCO on the same graph.
- Step 2: Increase the phase noise of the crystal reference by the noise contribution of the loop.
- Step 3: Convert the divide-by-N to dB ( $20 \log 8 \times N$ ) and increase the phase noise of the crystal reference by that amount.
- Step 4: The point at which the VCO phase noise crosses the amplified phase noise of the crystal reference is the point of the optimum loop bandwidth. This is approximately 15 kHz in Figure 30.
- Step 5: Correlate this loop bandwidth to the loop natural frequency per Figure 31. In this case the 3.0 dB bandwidth for a damping coefficient of 1 is 2.5 times the loop's natural frequency. The relationship between the 3.0 dB loop bandwidth and the loop's "natural" frequency will vary for different values of  $\zeta$ . Making use of the equations defined in Figure 32, a math tool or spread sheet is useful to select the values for  $R_O$  and  $C_O$ .

#### Appendix: Derivation of Loop Filter Transfer Function

The purpose of the loop filter is to convert the current from the phase detector to a tuning voltage for the VCO. The total transfer function is derived in two steps.

Step 1 is to find the voltage generated by the impedance of the loop filter.

Step 2 is to find the transfer function from the input of the loop filter to its output. The "voltage" times the "transfer function" is the overall transfer function of the loop filter. To use these equations in determining the overall transfer function of a PLL, multiply the filter's impedance by the gain constant of the phase detector, then multiply that by the filter's transfer function. Figure 33 contains the transfer function equations for the second, third, and fourth order PLL filters.

#### PSpice Simulation

The use of PSpice or similar circuit simulation programs can significantly reduce laboratory time when refining a PLL

Figure 31. Closed Loop Frequency Response for  $\zeta = 1$ 

design. The following describes the use of behavioral modeling to develop useful models for studying loop filter performance. In many applications the levels of sideband spurs can also be studied.

Behavioral modeling is chosen, as opposed to discrete device modeling, to improve performance and reduce simulation time. PLL devices can contain several thousand individual transistors. To simulate at this level can result in generation of an enormous amount of data when compared to a simpler behavioral model. For example, a logic NAND gate can contain several transistors. Each of these requires a data set for each of the transistor terminals. If a half dozen transistors are used in the gate design, both current and voltage measurements for each terminal of each device for every node in the circuit is calculated. The gate can be expressed as a behavioral model, which is treated and simulated as a single device. Since PSpice sees this as a single rather than multiple devices, the amount of accumulated data is much less, resulting in a faster simulation.

For applications using integrated circuits such as PLLs, it is desirable to investigate the performance of the circuitry added externally to the integrated circuit. By using behavioral modeling rather than discrete device modeling to represent the integrated circuit, the engineer is able to study the performance of the design without the overhead contributed by simulating the integrated circuit.

#### Phase Frequency Detector Model

The model for the phase frequency detector is derived using the waveforms shown in Figure 20. Two signals are present at the input of the phase frequency detector. These are the reference input and the feedback from the VCO and/or prescaler. The two signals are compared to determine the lag/lead relationship between the two signals and pulses generated to represent the leading edge of each signal. A pulse whose width equals the lead of one input signal over the other is generated by an RS flip-flop (RSFF). One RSFF generates a pulse whose width equals the lead of the reference signal over the feedback signal, and a second RSFF generates a signal whose width is the lead of the feedback signal over the reference signal. The logical model for the phase frequency detector is shown in Figure 34.

Figure 32. Design Equations for the Second Order System

$$T(s) = \frac{R_0 C_0 s + 1}{\left(\frac{N C_0}{K_p K_V}\right) s^2 + R_0 C_0 s + 1} = \frac{\left(\frac{2\zeta}{\omega_0}\right) s + 1}{\left(\frac{1}{\omega_0^2}\right) s^2 + \left(\frac{2\zeta}{\omega_0}\right) s + 1}$$

$$\left(\frac{N C_0}{K_p K_V}\right) = \left(\frac{1}{\omega_0^2}\right) \rightarrow \omega_0 = \sqrt{\frac{K_p K_V}{N C_0}} \rightarrow C_0 = \left(\frac{K_p K_V}{N \omega_0^2}\right)$$

$$R_0 C_0 = \left(\frac{2\zeta}{\omega_0}\right) \rightarrow \zeta = \left(\frac{\omega_0 R_0 C_0}{2}\right) \rightarrow R_0 = \left(\frac{2\zeta}{\omega_0 C_0}\right)$$

Figure 33. Overall Transfer Function of the PLL

$$Z_{LF}(s) = \frac{R_0 C_0 s + 1}{C_0 s}$$

$$T_{LF}(s) = \frac{V_t(s)}{V_p(s)} = 1, \quad V_p(s) = K_p(s) Z_{LF}(s)$$

$$Z_{LF}(s) = \frac{R_0 C_0 s + 1}{C_0 R_0 C_a s^2 + (C_0 + C_a) s}$$

$$T_{LF}(s) = \frac{V_t(s)}{V_p(s)} = 1, \quad V_p(s) = K_p(s) Z_{LF}(s)$$

$$Z_{LF}(s) = \frac{(R_0 C_0 s + 1) (R_x C_x s + 1)}{C_0 R_0 C_a R_x C_x s^3 + [(C_0 + C_a) R_x C_x + C_0 R_0 (C_x + C_a)] s^2 + (C_0 + C_a + C_x) s}$$

$$T_{LF}(s) = \frac{V_t(s)}{V_p(s)} = \frac{1}{(R_x C_x s + 1)}, \quad V_p(s) = K_p(s) Z_{LF}(s)$$

Figure 34. Phase Frequency Detector Logic Diagram

The behavioral model of the phase frequency detector shown in Figure 35 is derived using the phase frequency detector logic diagram. Behavioral models for the pulse generator, AND gate (Figure 36), and RS flip-flops (Figure 37) are created using analog behavioral blocks. The pulse generator is created using a delay block and a “gate” defined by the behavioral expression:

$$\text{If } [V(v1) \geq 1 \ \& \ V(v2) \ , \ 1, 5, 0]$$

$v1$  and  $v2$  represent the two inputs to the block.

This is the behavioral expression for an AND gate with one input inverted. The addition of the delay element produces a pulse whose width equals the delay element.

The pulses appearing at the output of HB1 and HB2 (Figure 35) are used to set the flip-flops, RSFF1, and RSFF2. The leading pulse will set the appropriate flip-flop resulting in a high at the output of that flip-flop. The output of this flip-flop will remain high until the arrival of the second (or lagging) pulse sets the second RS flip-flop. The presence of a high on both RS flip-flop outputs results in the generation of the reset pulse. The reset pulse is generated by the analog behavioral block (configured as an AND gate) and the delay element. The delay element is necessary to eliminate the zero delay paradox of input to output to input.

The output of the phase frequency detector is two pulse trains appearing at  $R_{\phi}$  and  $V_{\phi}$ . When the PLL is locked, the pulses in both pulse trains will be of minimum width. When the phase frequency detector is out of lock, one pulse train will consist of pulses of minimum width while the width of the pulses in the second train will be equal to the lead/lag relationship of the input signals. If the Ref input leads 'In', the pulse train at  $R_{\phi}$  will consist of pulses whose width equals the lead of Ref. If Ref lags 'In', the width of the pulses appearing at  $V_{\phi}$  will equal this lag.

The terms lead and lag used in this explanation represent an occurrence in time rather than a phase relationship. At any condition other than locked, one input (either In or Ref), will be of a higher frequency. This results in the arrival of the pulse at that input ahead of the pulse at the other input, or leading. The second then is lagging.

To simulate the operation of the phase frequency detector in an actual circuit, a charge pump needs to be added. The behavioral model for this is shown in Figure 38. Two voltage-to-current behavioral models are used to produce the charge pump output. Two voltage-controlled switches with additional behavioral models, monitor the voltage of the output of the charge pump and clamp to 0 or  $V_{CC}$  to simulate a real circuit.

To ensure the model conforms to the PLL, the delay blocks in the phase frequency detector should be set to the expected value as specified by the MC145181 data sheet. In addition, the charge pump sink and source current behavioral model should also be set to deliver the desired current and  $V_{CC}$  specified to ensure correct clamping.

### Modeling the VCO

The VCO (Figure 39) is also modeled using Analog Behavioral Modeling (ABM). The model used in the following examples assumes a linear response; however, the control voltage equation can be modified as desired. The circuit is modeled as a sine generator controlled by the control voltage. The sine generator can be modeled using the EVALUE function or the ABM function. In Figure 39, the EVALUE function is used to generate the divided output and the ABM function is used for the undivided output. Either the GVALUE or the ABM/I function can be used for the control voltage.

Figure 35. Behavioral Model of the Phase Frequency Detector

Figure 36. Behavioral Block Used for the Pulse Generator

Figure 37. Behavioral Block Used as an RS Flip-flop

# MC145225 MC145230

**Figure 38. Charge Pump Model**

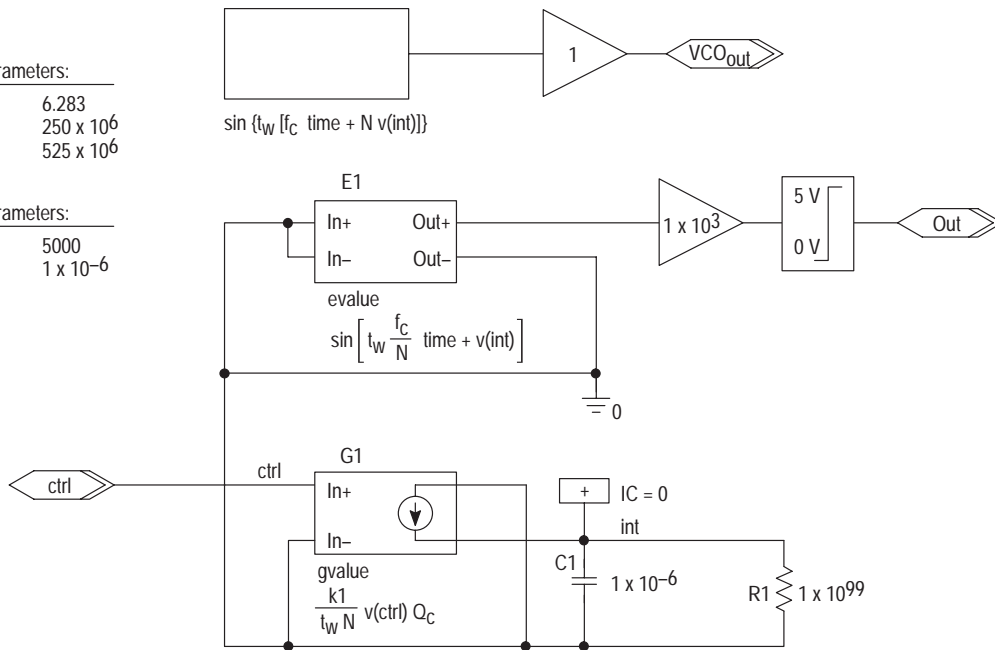

**Figure 39. VCO Behavioral Model**

Parameters:

$t_w$	6.283
$f_c$	$250 \times 10^6$
$k_1$	$525 \times 10^6$

Parameters:

$N$	5000
$Q_c$	$1 \times 10^{-6}$

The equation for the sine generator is:

$$e = \sin \left[ t_w \frac{f_c}{N} \text{ time} + v(\text{int}) \right]$$

$f_c$  is defined as the output frequency when the control voltage is 0. This is the expected VCO frequency before frequency division. For the purpose of simulation, the counter value,  $N$ , has been written into the equation to ensure the correlation between the modeled circuit and the mathematical loop filter calculations.  $t_w$  is  $2\pi$ ; additional decimal places can be added as needed.  $v(\text{int})$  is the control voltage effect and is defined in these examples as:

$$v(\text{int}) = \frac{k_1}{t_w N} v(\text{cntl}) 1 \times 10^{-6}$$

where  $k_1$  is the VCO gain in rad/V.

The value  $C_1$  in the schematic of the VCO can be arbitrarily changed; however, the value must match that of  $Q_C$ .  $Q_C$  determines the value of the current to be integrated by the capacitor  $C_1$ .  $R_1$  is arbitrarily set to  $1 \times 10^{99}$  and is not an active part of the circuit; however, it must be included to prevent open pin errors from the PSpice software. The GVALUE function is used to perform the generation of  $v(\text{int})$ . There is some interaction between the integrator, (GVALUE output and  $C_1$ ) and  $R_1$ .  $V(\text{int})$  is a continuous ramp that is loaded by the resistance of  $R_1$ . Unless the GVALUE output current is sufficiently large for the value chosen for  $R_1$ , the VCO control voltage required to maintain lock will increase throughout the simulation producing nonlinear operation. Modifications to the circuit can be performed either by changing the values in the parameter list or for major changes to the VCO characteristics, the equations for the sine generator, or control voltage can be altered.

The output of the sine generator is amplified by 1000 to produce a sharp rise/fall time and the output limited to swing between the values of 0 V and 5 V to convert it to a digital output. The resultant circuit/symbol accepts a voltage input from the loop filter and produces a square wave output at the

desired frequency. This frequency should be chosen to represent the frequency present at the output of the  $N$  counter of the PLL frequency synthesizer.

The second output represented by the ABM function is a sine wave output of the frequency expected from the actual VCO. The primary purpose of this output is to allow full frequency simulation for spectrum analysis. By running a transient analysis of sufficient time, it is possible to determine spur content and level. If sufficient resolution is used in the simulation, the PSpice probe FFT transform can be used to provide the typical spectrum analyzer display.

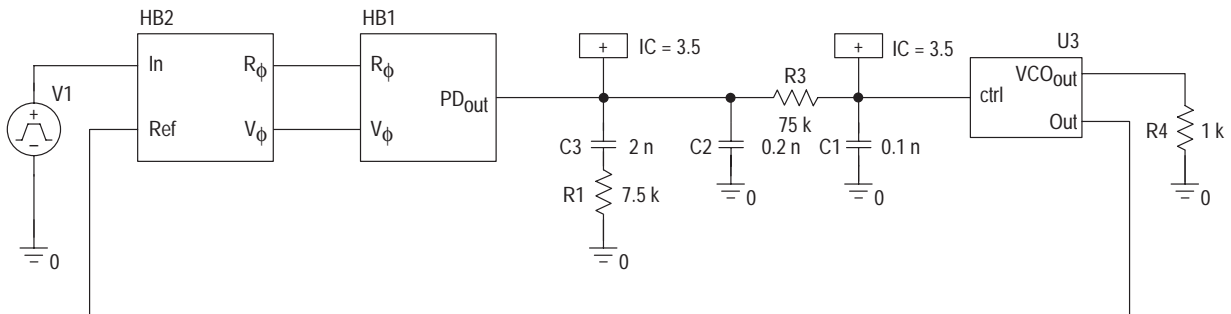

**Loop Filter Simulation**

The circuit shown in Figure 40 is used to simulate the closed loop operation for a single charge pump output. Component values for the loop filter should be computed using information from the previous section. Initial conditions can be set using the "IC1" symbol with starting values specifying the initial condition.

By adjusting component values for the loop filter, performance of the closed loop operation can be monitored. The control voltage to the input of the VCO can be monitored for a variety of conditions including settling time, lock time, and ripple present at the VCO input. In addition, the output of the VCO can be monitored for spur sidebands caused by ripple on the loop filter output; however, expected operation at high frequencies may be difficult due to the excessive data that can be generated.

As the divider ratio,  $N$ , increases for a fixed step frequency, the number of data points required to obtain sufficient information to overcome aliasing problems may become excessively large. In addition, the number of samples required should be three or more per cycle. For VCO frequencies in the range of 500 MHz, this means the step ceiling needs to be in the range of 100 to 500 ps. If a simulation time of 1 ms is needed, the actual computer time can be several hours with data accumulation in the 1- to 2-Gbyte range.

**Figure 40. PLL Closed Loop Model**

7C. MAIN LOOP FILTER DESIGN — ADAPT

Introduction

For PSpice simulation, the schematic model shown in Figure 41 was chosen. The classical PLL model employing a phase–frequency detector, a VCO, and an adaptive loop filter is used to simplify visualization of circuit operation. The parameter tables allow for modification of circuit performance by providing an easy method for altering critical values without necessitating changes to sub–level schematics. The definition for the terms are:

- $t_w = 2\pi$ ,
- $f_r$  = reference frequency,
- $t_d$  = time delay; allows delay of the start of the high current mode (used to perform reference spur measurements),
- CPL = charge pump low current,
- CPH = charge pump high current,
- N = N counter value,

- $S_z$  = amount the N counter is being increased (or decreased) by,
- $S_t$  = number of  $f_r$  cycles that CPH is active; this value is either 16, 32, 64, or 128,
- VCPHH = charge pump voltage – high,
- VCPHL = charge pump voltage – low,
- K1 = VCO gain (Hz/volt),
- $f_c$  = VCO frequency at 0 V control voltage,
- H = reference spur scaling factor.

Modeling the Phase–frequency Detector

Figure 42 is a schematic of the phase–frequency detector. It includes the reference oscillator model, phase–frequency detector model, and charge pump models. V1 is the control element used to generate the step time for switching between CPL and CPH. The signal source VPULSE, is used to simulate the timer that controls when CPL and CPH are turned on. PW calculates the pulse width that simulates the counter from the values for  $S_t$  and  $f_r$  that are entered in the parameter tables on the top level schematic.

Figure 41. Top Level PLL Model

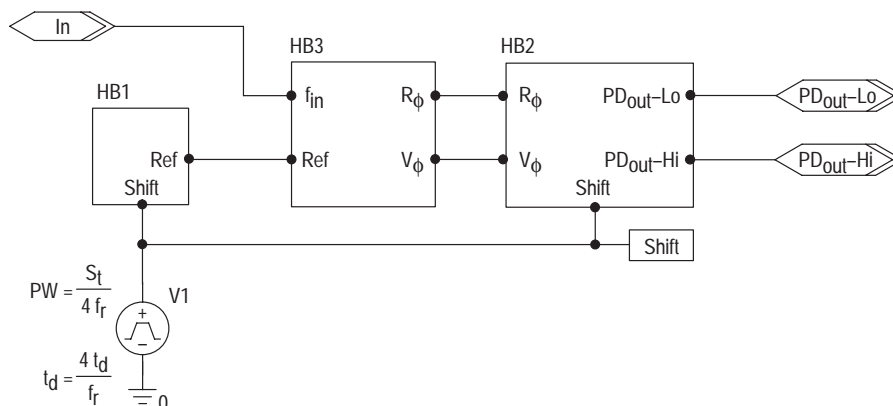

Figure 42. Phase–frequency Detector with Dual Charge Pumps

**Reference Oscillator**

The reference oscillator is shown in Figure 43. The oscillator is modeled using an analog behavioral block. The function for the block is written as an "If" condition. If the signal shift is low, the reference frequency  $f_r$  will be generated if shift is high, a signal of four times  $f_r$  will be generated. The limiter/gain block converts the low level sine wave output of the analog behavioral block into a square wave. The values of 0 for the low value and 5 for the high value are used throughout. These values are chosen out of habit and are not critical in an analog behavioral environment, providing the conformity is universal throughout the design.

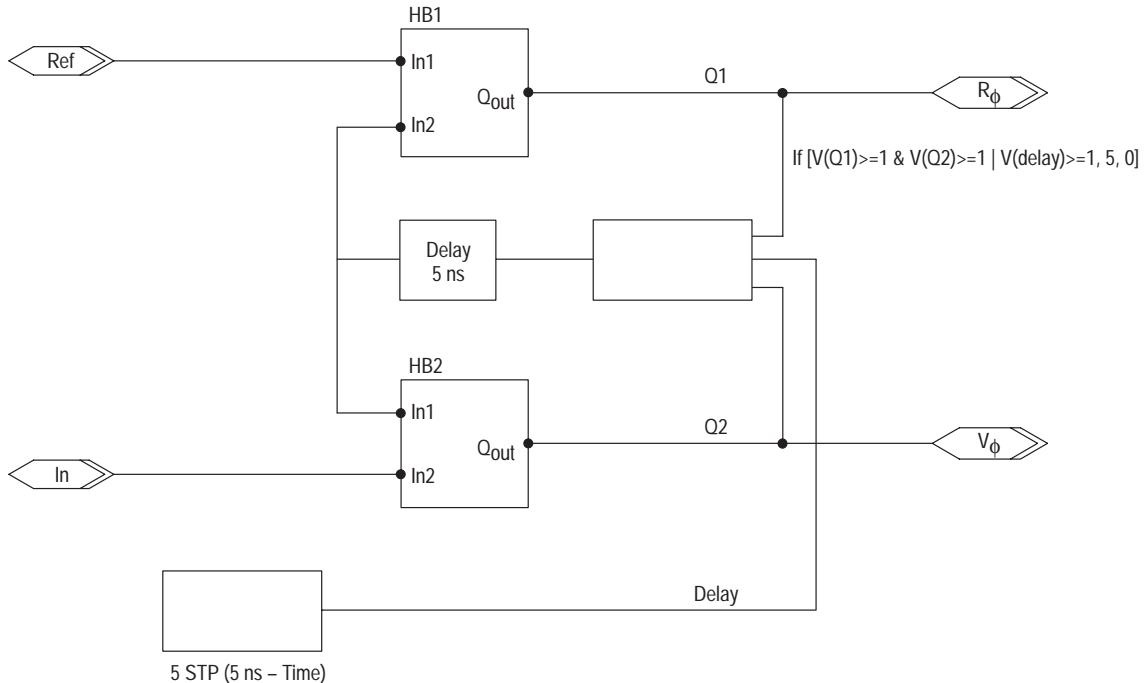

**Figure 43. Reference Oscillator**

**Phase-frequency Detector**

The actual phase-frequency detector model minus reference oscillator and charge pumps is shown in Figure 44. The detector is composed of three delay modules: a behavioral AND gate, and two RS flip-flops. The STP function resets the phase/frequency detector logic on initiation of the simulator. The circuit for the behavioral RS flip-flop is shown in Figure 45.

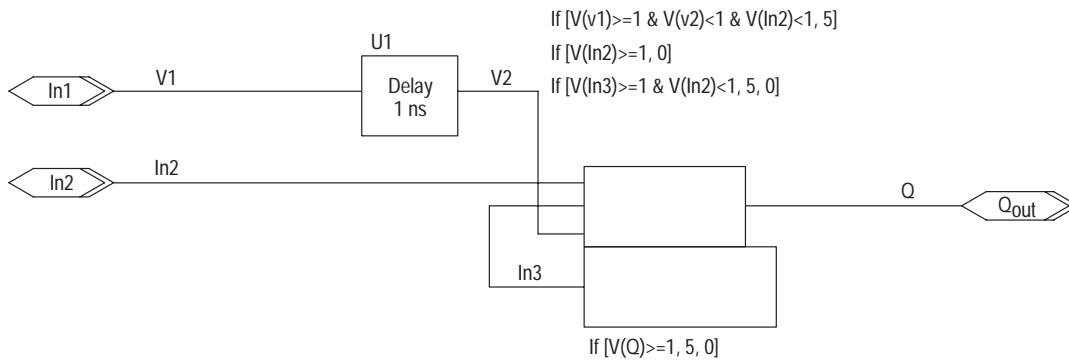

**Figure 44. Phase-frequency Detector Logic**

The RS flip-flop equation illustrates the benefit of using the behavioral block instead of using a primitive logic element. A delay block and the behavioral gate equation generate a pulse whose width is equal to the value of the delay block. To generate the output using a primitive logic element such as a NAND gate, an inverter would be necessary to invert one of the NAND inputs. This approach requires three elements to be used instead of the two of the behavioral approach just for the pulse generator. In the behavioral approach, the equation for the behavioral AND gate is folded into the RS flip-flop, eliminating a separate gate altogether. Constructing the model with classic logic elements would require two NOR gates for the flip-flop, a delay element, an inverter, and an AND gate; five elements as compared with three for the behavioral approach. Since the RS flip-flop is used in two places in the model, four less components are needed for simulation. Since the speed of the simulation is directly impacted by the number of components being simulated, any reduction in the total number of components is a savings in simulation time and computer memory.

The RS flip-flops generate the lead or lag outputs that are used to "steer" the VCO. The pulse generator equation produces narrow pulses coincident with the leading edge of each of the input signals. These pulses set the appropriate RS flip-flop. Once set, the leading flip-flop must wait until the lagging flip-flop is also set. The behavioral AND gate provides the necessary output pulse to reset the flip-flops. The delay element placed at the output of the behavioral AND gate prevents an undefined state for the detector. The value 5 ns is chosen to correspond with the data sheet. The logic functions as a three state phase/frequency detector with an operating range of  $\pm 2\pi$ .  $R_\phi$  and  $V_\phi$  deliver positive pulses, whose width represents the amount of the lead of each input over the other input.

Figure 45. Behavioral RS Flip-flop

**Charge Pump Model**

The schematic used for the charge pump in the phase-frequency detector model is shown in Figure 46. Each charge pump is made from two analog behavioral blocks. The blocks chosen are three input behavioral blocks with current outputs. The two blocks are connected in push-pull to generate the appropriate source and sink output. The output of each block is defined using an “If” statement to monitor the input signals and generate the correct output at the appropriate time.

One note about this type of design. SPICE does not limit the output voltage swing necessary to generate the programmed current. It is possible to implement values for the loop filter, which will cause the charge pump to exceed the rail voltage. To limit the output voltage to prevent exceeding the value of the rails, the two behavioral blocks, voltage-controlled switches S1 and S2, and constants VCPHH and VCPHL are added. S1 and S2 on/off resistance is set to 1 Ω and 1 x 10<sup>12</sup> Ω, and the off/on voltage is set to 0 V and 1 V to correspond to the behavioral blocks. The values defined by the constants are accessible from the parameter tables on the top level schematic.

**VCO Model**

The model used for simulating the VCO is shown in Figure 47. The VCO is composed of a sine wave generator and a control element. An analog behavioral block is used as a sine wave generator and a GVALUE element is used as a control element. The GVALUE is operated as an integrator. The output of the integrator is defined as

$$v(int) = k1 v(ctrl) Q_C$$

The block designated to provide the feedback to the phase-frequency detector uses a single input analog behavioral block. The signal shift generated by V1 in the phase-frequency detector block is used to define the output frequency of the behavioral block. In this manner, the switching of the N and R values for the programmable counters can be simulated. In the implementation shown, the two frequencies will be either 25 kHz or 100 kHz when locked to the reference oscillator.

The other behavioral block is used to generate a VCO output dependent on the loop, but not contributing to the operation of the loop. This is used to emulate the actual VCO output with one modification. “H” has been added to the equation generating the sine wave. If H is defined as 1, the sine wave generated will be the same as the expected VCO output. If H is chosen as some value greater than 1, the frequency of the output will be reduced accordingly. This is useful when running simulations designed to show reference spur levels.

In cases where it is desirable to view reference spur levels, simulation can become difficult or impossible. For example, consider the circuit that is being discussed. This circuit represents the evaluation kit (MC145230EVK) using a VCO tunable between 733 MHz to 742 MHz, with a step frequency of 25 kHz.

**NOTE**

This example is for reference only. The maximum operating frequency of the MC145181 is 550 MHz. Operation of the VCO at frequencies greater than 550 MHz requires the inclusion of additional external division such as a prescaler.

To obtain useful information from the simulation, a sampling rate greater than the Nyquist limit must be used (three to five samples per cycle). This dictates a step size less than 1/2 nanosecond. Additionally, the reference frequency is only 25 kHz. To accurately represent the conditions for spur generation, the simulation time must be long enough to include a sufficient number of  $f_r$  periods. Otherwise, no spurs are generated. In addition, the data file system is limited to 2 Gbyte, either in the NT 4.0 operating system or in PSpice itself. If the file exceeds 2 Gbyte, the data is discarded. To simulate reference spur generation at 730 MHz, a 1 ms simulation time was chosen. The simulation ran for several hours and generated a data file just under 2 Gbyte. The result is shown in Figure 48. The plot obtained from the EVK is shown in Figure 49 for comparison.

# MC145225 MC145230

Figure 46. CPL and CPH Charge Pumps

# MC145225 MC145230

Figure 47. VCO Model

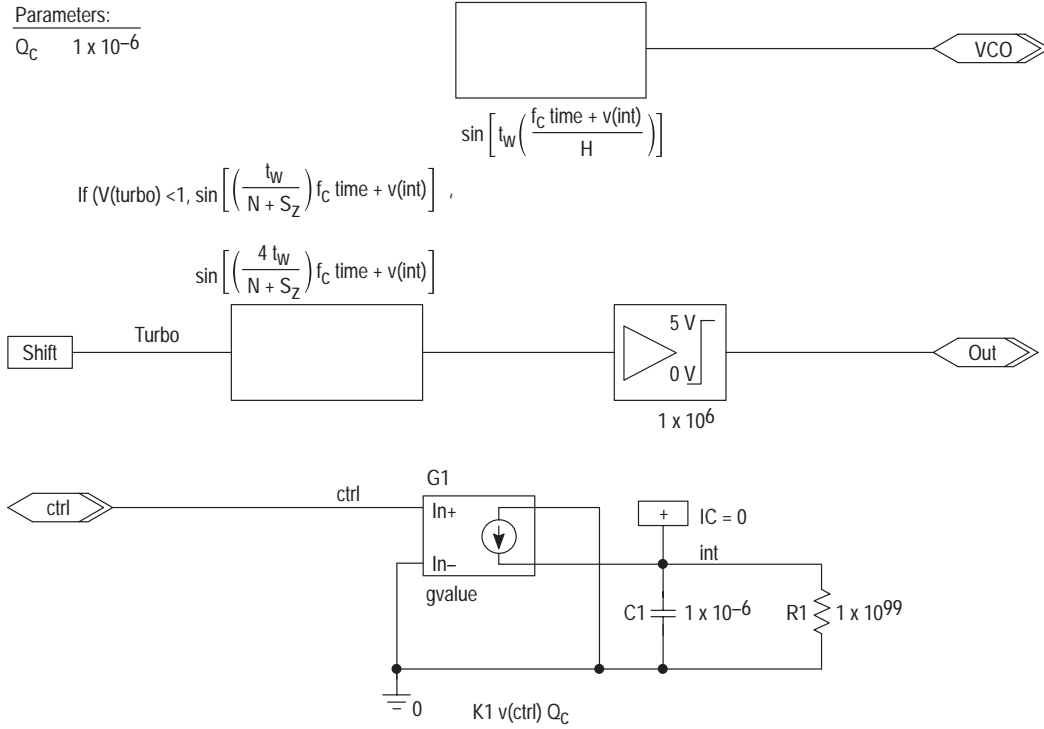

Figure 48. Reference Spur Simulation at 730 MHz

Figure 49. Sybil EVK Reference Spur Measurements

It should be noted that the reference spur values obtained from the simulation are lower than the values obtained from the actual EVK. This is because the simulation model is an “ideal” modeling of the PLL. To obtain results closer to the actual implementation, the models should be “massaged” to be more representative of the actual circuit. For example, spur levels more consistent with actual circuitry can be obtained by adding a resistance to ground at the input of the VCO to represent leakage. The value chosen should be consistent with VCO and circuit component performance.

To reduce simulation time, the H value may be used. By reducing the frequency of the VCO output, the number of samples required for simulation can also be reduced. The output shown in Figure 50 shows the result of dividing the VCO output of 730 MHz by 7.3 to produce a 100 MHz output. The reference spurs are better represented since adequate simulation time is possible.

To generate these outputs, the parameter values used were those shown on the top level schematic. The simulator was set to run a transient sweep, with  $t_d$  set for a delay that would prevent the 4X frequency from being started. The initial conditions were set to 1 V and the simulation run for 1 ms. VCO was monitored and the probe display button FFT was initiated. The X and Y axis were adjusted to those shown.

Note: These simulations are presented as the result of “ideal” models and may not accurately display real hardware. It would be best to load the VCO input with additional leakage devices such as a large resistance, to accurately display real

conditions. These models are starting points for more accurate implementations.

Loop filter analysis is more accurate, since the predominate factors are in the loop filter itself. To simulate the performance of the loop filter,  $t_d$  is set for 0, N is set to the desired divider value, and  $S_z$  is set to the desired step. For this example, 733 MHz was chosen.

#### NOTE

These values are for reference only. The maximum operating frequency of the MC145181 is 550 MHz. For VCO frequencies greater than 550 MHz, an added external divider such as a prescaler is necessary.

With the VCO model shown,  $V(\text{ctrl}) = 0$  produces an output of 727.6 MHz and at  $V(\text{ctrl}) = 1.35$  V, the VCO frequency would be 733 MHz; the minimum MC145230EVK default operating frequency. To show the response of the loop filter to a 10 MHz step at this operating frequency,  $S_z = 10$  MHz/25 kHz = 400. The simulation is run for 1 ms with a step ceiling of 100 ns. The result is shown in Figure 51.

If the simulation is examined over a longer period of time, the long term settling can be compared to the performance of the actual circuitry. The plot shown in Figure 52 shows the VCO control voltage with the display resolution set to 1 mV. This compares to the plot of frequency variation measurements made on the actual EVK. This plot is shown in Figure 53.

# MC145225 MC145230

Figure 51. 10 MHz Step for an Operating Frequency of 729 MHz

Figure 52. VCO Settling

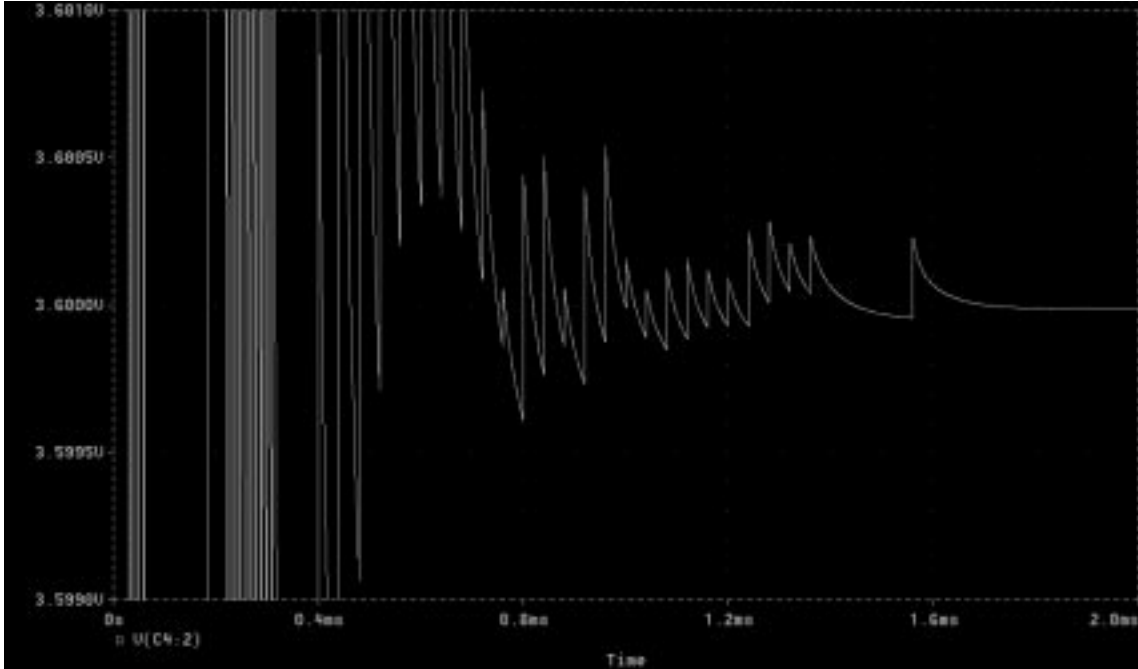

Figure 53. Frequency Settling of the EVK

## MC145225 MC145230

It is noted that the results obtained from the simulation compare favorably to those obtained from the measurements of the EVK. The simulation display resolution is adjusted to represent the same  $\pm 4$  kHz deviation as shown in Figure 53. Since variation in VCO control voltage is equal to the VCO frequency divided by the VCO gain, this axis may be redefined to show change in frequency rather than change in control voltage.

The models shown represent a "skeleton" that may be used to develop extensive and reliable simulations that can greatly reduce actual breadboarding and testing. In addition to the basic simulations shown, PSpice provides a method by which worst case and Monte Carlo evaluation can be

performed on all, or selected components. By limiting the circuit to minimum necessary components, simulation can be performed using only the PSpice evaluation copy. In addition, the optional PSpice program Optimizer should allow refining the loop filter more easily.

While PSpice is a powerful tool, it is not without limits. Since it was designed to run on large mainframe computers, the PC is just now becoming powerful enough to make use of the capability of the simulator. A fast Pentium class processor with a large RAM and a hard drive of the Gbyte size is a necessity. Even with the most judicious planning, some simulations will "bump" the limits of the system.

7D. SECONDARY LOOP FILTER DESIGN

Low Pass Filter Design for PD<sub>out</sub>'

The design of low pass filtering for PD<sub>out</sub>' for the device can be accomplished using the following design information. In addition to the example included here, Motorola Application Note AN1207, also includes examples of active filtering which may be used to supplement this information.

$$\omega_n = \sqrt{\frac{K_\phi K_{VCO}}{NC(R_1 + R_2)}}$$

$$\zeta = 0.5 \omega_n \left( R_2 C + \frac{N}{K_\phi K_{VCO}} \right)$$

$$F(s) = \frac{R_2 s C + 1}{(R_1 + R_2) s C + 1}$$

Definitions:

N = Total Division Ratio in Feedback Loop

K<sub>φ</sub> (Phase Detector Gain) = V<sub>DD</sub> / 4π V/radian for PD<sub>out</sub>'

K<sub>φ</sub> (Phase Detector Gain) = V<sub>DD</sub> / 2π V/radian for φ<sub>φ</sub> and φ<sub>R</sub>

$$K_{VCO} \text{ (VCO Gain)} = \frac{2\pi \Delta f_{VCO}}{\Delta V_{VCO}}$$

For a nominal design starting point, the user might consider a damping factor ζ ≈ 0.7 and a natural loop frequency ω<sub>n</sub> ≈ (2πf<sub>R</sub>/50), where f<sub>R</sub> is the frequency at the phase detector input. Larger ω<sub>n</sub> values result in faster loop lock times and, for similar sideband filtering, higher f<sub>R</sub>-related VCO sidebands.

Example:

Given the following information:

VCO frequency = 45.555 MHz,

Frequency step size = 5 kHz,

VCO gain = 3.4 MHz/V.

Design a loop filter with a damping factor of 0.707.

The VCO is assumed to have a linear response throughout the range used in this example. The gain for the VCO has been given as 3.4 MHz/V and is multiplied by 2π rad/s/Hz for calculating loop filter values.

$$K_{VCO} = 2\pi \text{ rad/s/Hz} \times 3.4 \text{ MHz/V} = 2.136 \times 10^7 \text{ rad/s/V}$$

The gain for the phase detector is defined as

$$K_\phi = \frac{V_{DD}}{4\pi} \text{ V/rad for PD}_{out}'$$

Using a value for V<sub>DD</sub> (phase detector supply voltage) of 3.6 V with the output voltage multiplier turned off, the value is

$$K_\phi = \frac{3.6}{4\pi} = 0.2865 \text{ V/rad}$$

Let

$$\omega_n = \frac{2\pi f_R}{50} = 628.3 \text{ rad/s}$$

and

$$N = \frac{F_{VCO}}{F_{\text{step size}}} = \frac{45.555 \text{ MHz}}{5 \text{ kHz}} = 9111$$

Choosing C = 0.05 μF and calculating R<sub>1</sub> + R<sub>2</sub>,

$$R_1 + R_2 = \frac{K_\phi K_{VCO}}{N C \omega_n^2} = 34 \text{ k}\Omega$$

With a damping factor of 0.707,

$$R_2 = \frac{\frac{0.707}{0.5 \omega_n} - \frac{N}{K_\phi K_{VCO}}}{C} = 15 \text{ k}\Omega$$

$$R_1 = (R_2 + R_1) - R_2 = 34 \text{ k} - 15 \text{ k} = 19 \text{ k}\Omega \sim 20 \text{ k}\Omega$$

The choice for C is somewhat arbitrary, however, its value does impact the performance of the loop filter. If possible, a range of choices for C should be used to calculate potential loop filters and the resultant filters simulated, as will be shown below, to determine the best balance.

## MC145225 MC145230

If additional filtering is desired, R1 may be split into two equal resistors and a capacitor to ground inserted. Since the closest resistance to one-half of 9 k is 4.7 kΩ, this value is chosen for R1<sub>a</sub> and R1<sub>b</sub>. The maximum value for the added capacitance is based on the bandwidth of the original loop filter.

The general form for the transfer function for the passive filter shown in Figure 54, can be shown to have the form:

$$F(s) = K_h \left[ \frac{s + \omega_2}{(s + \omega_1)(s + \omega_3)} \right]$$

where

$$\omega_1 = \frac{1}{(R1_a + R1_b + R2) C}$$

$$\omega_2 = \frac{1}{R2 C}$$

$$\omega_3 = \frac{1}{\left[ \frac{R1_a R1_b + R1_a R2}{(R1 + R2)} \right] C_c}$$

where

$$R1 = R1_a + R1_b$$

and

$$\omega_3 > \omega_2$$

Since splitting R1 into two equal values, R1<sub>a</sub> and R1<sub>b</sub>, and inserting the capacitance between the junction of R1<sub>a</sub> and R1<sub>b</sub> does not change the position of the pole located at ω<sub>1</sub>, the value of ω<sub>1</sub> remains

$$\omega_1 = \frac{1}{(R1_a + R1_b + R2) C} = \frac{1}{(R1 + R2) C}$$

The 0 identified at ω<sub>2</sub> = 1/R2 C is also unaffected by the addition of C<sub>c</sub> if ω<sub>3</sub> > ω<sub>2</sub>.

Since

$$R1_a = R1_b = \frac{R1}{2}$$

the value of C<sub>c</sub> can be determined by specifying the value for ω<sub>3</sub> and using the values already determined for R1 and R2. The rule of thumb is to choose ω<sub>3</sub> to be 10 x ω<sub>B</sub> so as not to impact the original filter. ω<sub>B</sub> can be found as

$$\omega_B = \omega_n \sqrt{[1 + 2\zeta^2 + \sqrt{(2 + 4\zeta^2 + 4\zeta^4)}]}$$

$$\omega_B = 628.3 \text{ rad/s} \sqrt{[1 + 2(0.707)^2]}$$

$$+ \sqrt{(2 + 4(0.707)^2 + 4(0.707)^4)}}$$

$$= 1.293 \times 10^3 \text{ rad/s}$$

$$10 \omega_B = 12.93 \times 10^3 \text{ rad/s}$$

The circuit for the passive loop filter is shown in Figure 54. R1 is split into two equal values and C<sub>c</sub> inserted at the

junction of R1<sub>a</sub> and R1<sub>b</sub>. Using the values defined above, C<sub>c</sub> is determined to be

$$C_c = \frac{1}{\left[ \frac{R1_a R1_b + R1_a R2}{(R1 + R2)} \right] \omega_3}$$

$$= \frac{1}{\left[ \frac{R1_a R1_b + R1_a R2}{(R1 + R2)} \right] 10} \omega_B = 10.83 \text{ nfd} \sim 10 \text{ nfd}$$

Figure 54. Passive Loop Filter for PD<sub>Out</sub>'

### Open Loop AC Analysis of the Loop Filter

AC analysis is chosen for the mode of simulation for PSpice and VSIN is chosen for V1 and is set to produce a 1 V peak output signal. The simulation is then run and the result shown in Figure 55.

A Bode plot of the loop filter is obtained which describes the open loop characteristics of the loop filter. The corner frequencies of the filter can be modified and the simulation rerun until the desired wave shape is obtained. Since AC analysis runs much faster than transient analysis, the AC open loop analysis of the loop filter is much quicker and requires less resources than the closed loop transient analysis.

### Closed Loop Filter Simulations Using PSpice

The top level schematic for simulating a simple loop filter for PD<sub>Out</sub>' operating closed loop, is shown in Figure 56. This filter uses the values calculated above.

The schematic represents the PLL function using the internal phase detector, PD<sub>Out</sub>', the loop filter calculated above, and a VCO. The parameter table allows altering the divider value of N, the maximum current obtained from PD<sub>Out</sub>', and PD<sub>Out</sub> charge pump voltage from the top level schematic.

The schematic for the VCO is shown in Figure 57. Analog behavioral modeling is used rather than discrete transistor modeling to reduce component count and improve simulation efficiency.

The behavioral VCO is composed of an integrator that transforms the input ctrl into the voltage control V(int) and a sine wave generator function whose frequency is controlled by V(int). EVALU and GVALUE functions are used to perform the transforms. The analog behavioral models, ABM and ABMI, can also be used.

# MC145225 MC145230

Figure 55. Bode Plot of the Passive Loop Filter

Figure 56. Passive Loop Filter

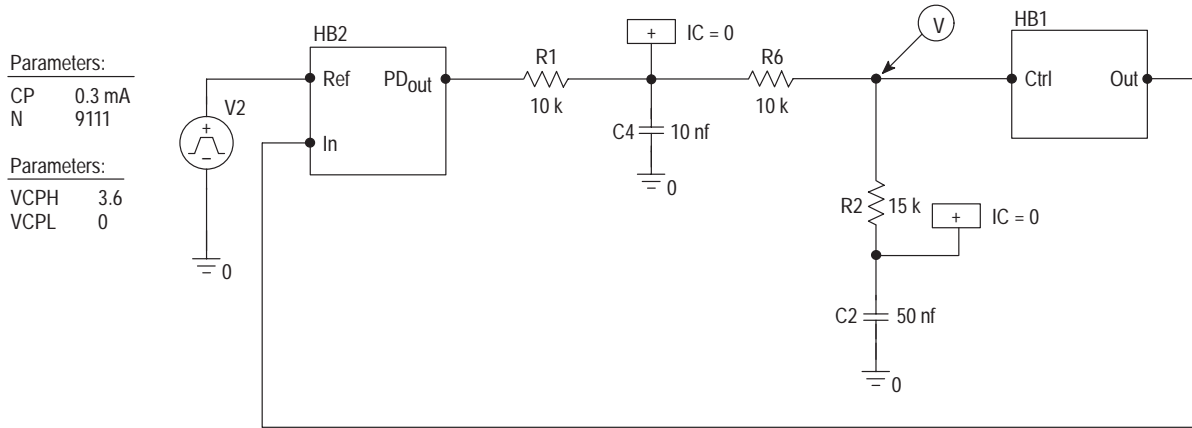

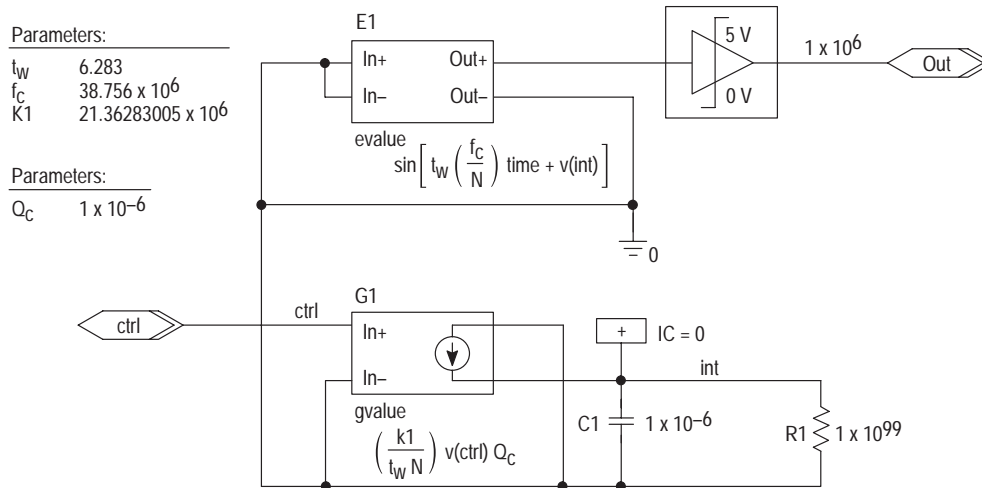

Figure 57. VCO Behavioral Model

G1 performs the operation  $[k1/(t_w N)] v(ctrl) Q_C$ . This integrates the input ctrl to produce a voltage ramp used by E1 to produce the desired output. This input is integrated by C1 whose value should equal  $Q_C$  for most applications. R1 is required by SPICE to prevent a floating node error.

E1 performs the calculations necessary to generate a sine wave of the desired frequency based on the values listed in the parameter tables and the value of ctrl. The output of E1 is multiplied by  $1 \times 10^6$  and limited to 0 and 5 to obtain a square wave with a fast rise/fall time. Since I/O\_STM is a standard model whose values are 0 and 5, these are used here and in the phase detector rather than modifying the component libraries.

The parameter tables provide a convenient method for setting VCO parameters.  $t_w$  is  $2\pi$ ,  $f_c$  is the zero control voltage VCO frequency, and K1 is the VCO gain in rad/s/V.

The sub-schematic for the phase/frequency detector section of the drawing is shown in Figure 58. This is composed of two blocks, HB3 and HB4. HB3 performs the PD<sub>Out'</sub> function with HB4 performing the actual phase detector operation.

The circuit for the phase/frequency detector is shown in Figure 59. The model is made up of two pulse generators, two RS flip-flops, and appropriate behavioral gates.

HB1 and HB2 are RS flip-flops. These are constructed from behavioral blocks as shown in Figure 60. A behavioral AND gate with a 5 ns delay completes the three state ( $\pm 2\pi$ ) phase/frequency detector. The STP function ensures the RS flip-flops are reset at initiation.

To perform the phase detector function, the Ref and  $f_{in}$  inputs of the behavioral RS flip-flops are configured to simulate edge triggered operation. This is achieved by placing a 1 ns delay in the Ref and  $f_{in}$  signal paths. The input and output of the delay are compared by the input behavioral block and interpreted as a 1 ns pulse. These pulses are used to set HB1 and HB2. If  $f_{in}$  leads Ref, the In flip-flop, HB2, will be set first. When Ref leads  $f_{in}$ , the Ref flip-flop, HB1, will be set first. The lagging edge drives the second flip-flop output high and the behavioral AND gate then resets both flip-flops. The delay line at the output of the behavioral AND gate prevents PSpice from being confused and also completes the simulation of the phase detector. The outputs of the two RS flip-flops are labeled  $R_\phi$  and  $V_\phi$ . The time between the

leading and lagging edges is reflected in the pulse width of the leading edge flip-flop. The lagging edge flip-flop will display a narrow pulse equal in width to the value chosen for the delay at the output of the behavioral AND gate. This should be programmed to the minimum value as specified by the data sheet and is usually 5 ns or less.

Since the outputs  $R_\phi$  and  $V_\phi$  are pure logic signals, additional circuitry is necessary to produce the output PD<sub>Out'</sub>. This output should be high impedance when not driving, and pull either high or low depending on which function ( $R_\phi$  or  $V_\phi$ ) is active. The circuitry shown in Figure 61 performs this function.

To eliminate the need for discrete modeling of PD<sub>Out'</sub>, analog behavioral modeling is used. Analog behavioral blocks ABMI/2, generate a current source/sink output whenever the appropriate input is high.

A second set of behavioral blocks monitor the output drive, and switch on the appropriate voltage controlled switch whenever the output rises to the value of  $V_{DD}$  (phase detector supply voltage) or drops to 0.

To model PD<sub>Out'</sub>, either a model of the transistors used for PD<sub>Out'</sub> must be used or this behavioral arrangement can be used. Since the output is specified by a specific output level and current capability, this arrangement suffices. The output swing becomes VCPH in the schematic and the current capability is CP. If a non-zero value is desired for  $V_{IO}$ , the value VCPL is adjusted from the parameter table on the top level schematic.

This arrangement allows setting the output voltage swing of PD<sub>Out'</sub> by specifying VCPH, the current drive of PD<sub>Out'</sub> by specifying the desired value for CP, and leakage values can be simulated by setting the appropriate attributes for S1 and S4 or by adding additional resistance.

### Simulation

Figures 62 and 63 are the simulation results of running a transient analysis on the example shown above. The time to lock from power on is simulated by setting the initial condition (IC1) to 0 and running the simulation. Figure 62 is the time versus value of the VCO control voltage. Figure 63 shows the output at the input of the loop filter and can be used to determine lock time.

### Summary

PSpice provides a method by which the performance of PLL circuitry can be simulated prior to, or in addition to, laboratory testing. The use of behavioral modeling allows the creation of simulation circuits that can provide valuable information for loop filter design and adjustment. By judicious

attention to VCO modeling, expected output characteristics can be verified prior to laboratory testing. While simulation does not replace laboratory testing, it can be used to find solutions to “what if” questions without the need for extensive empirical data gathering.

**7E. VOLTAGE MULTIPLIER STALL AVOIDANCE**

There are three important criteria to note, highlighted in the following sections: **Allowing for Voltage Build**, **Ensuring Valid Counter Programming**, and **Allowing for Overshoot**. Violation of any of these may cause the voltage multiplier to collapse. Once the voltage collapses, the loop goes out of lock and can not recover until the voltage is allowed to build up again. For an active loop, the voltage multiplier is designed to *maintain* the multiplied voltage on the phase/frequency detector supply pin (C<sub>mult</sub>). If the main loop is active, the multiplier cannot build the voltage.

**Allowing for Voltage Build**

After power up, a sufficient time interval must be provided for the on-chip voltage multiplier to build up the voltage on the C<sub>mult</sub> pin. During this interval, the phase/frequency detector outputs for the main loop (PD<sub>out-Hi</sub> and PD<sub>out-Lo</sub>) must be inactive (floating outputs). The POR (power-on reset) circuit forces this “float” condition, thus allowing the voltage to build on the C<sub>mult</sub> pin.

The duration of the interval to build the voltage is determined by the external capacitor size tied to the C<sub>mult</sub> pin and the charging current which is 100 μA minimum. The following formula may be used:

$$T = CV/I$$

where

- T is the interval in seconds,
- C is the C<sub>mult</sub> capacitor size in farads,
- V is the desired voltage on C<sub>mult</sub> in volts, and
- I is the charging current, 1 x 10<sup>-4</sup> amps.

The desired voltage on C<sub>mult</sub> is 4 V for a nominal 2 V supply and 5 V for any supply above 2.6 V.

After this interval, the chip can maintain the voltage on the C<sub>mult</sub> pin and the phase detectors may be safely placed in the active state.

The interval above also applies when the voltage multiplier is turned off (with power applied) via bits R'19 R'18 R'17 being 000. After the multiplier is turned back on, sufficient time must be allowed for the voltage to build on C<sub>mult</sub>. In this case, typically an external resistor does not allow the C<sub>mult</sub> voltage to discharge below approximately V<sub>pos</sub> (see Section 5E, under **C<sub>mult</sub>**). Note that if the voltage multiplier is NOT turned off (that is, the above bits are unequal to 000), the keep-alive circuit maintains the multiplied voltage on C<sub>mult</sub>.

**Ensuring Valid Counter Programming**

Before the PLLs and/or phase detectors are taken out of standby, legitimate divide ratios (pertinent to the application) must be loaded in the registers. For example, proper divide ratios must be loaded for the R, N, R', and N' counters. Also, proper values for all other bits must be loaded. For example: selection of crystal or external reference mode must be made prior to activation of the loops.

After the IC is initialized with the proper bits loaded, the main loop may then be safely activated via the phase detector float bit and/or the PLL standby bit being programmed to 0.

**Allowing for Overshoot**

The VCO control voltage overshoot for the main loop must not be allowed to exceed the capability of the phase/frequency detectors' maximum output voltage. The

detectors' maximum output voltage is determined by the minimum voltage at C<sub>mult</sub> and the headroom required for the current source. See the following figure.

For example, if the main supply voltage (V<sub>pos</sub>) is 3 V and the voltage multiplier is utilized, the minimum voltage at C<sub>mult</sub> is 4.75 V. Then, to allow for current source headroom, the maximum output voltage from the parameter table in Section 3C is approximately C<sub>mult</sub> - 0.6 V or 4.2 V approximately. Thus, the maximum output overshoot voltage at the phase/frequency detector outputs should be no more than 4.2 V.

Continuing the above example, if the loop is designed with 20% overshoot in the VCO control voltage, then the overshoot must be subtracted off of the 4.2 V shown above. Therefore, the upper end of the control voltage to the VCO must be no more than approximately 3.64 V.

The equations below can be used to determine constraints:

$$\Delta V \leq \frac{V_{\phi} - 1.2}{2\alpha + 1}$$

$$SSV_{max} = V_{\phi} - \alpha (\Delta V) - 0.6$$

where

ΔV is the VCO control voltage range, the maximum minus the minimum voltage,

V<sub>φ</sub> is the minimum phase detector supply voltage (at the C<sub>mult</sub> pin) per the following table,

α is the control voltage overshoot in decimal; for example, 20% overshoot is 0.2, and

SSV<sub>max</sub> is the maximum allowed steady-state VCO control voltage.

**MINIMUM PHASE DETECTOR VOLTAGE FROM VOLTAGE MULTIPLIER**

Supply Voltage, V <sub>pos</sub>	Minimum Phase Detector Voltage, V <sub>φ</sub>
1.8 V	3.32 V
2.0 V	3.72 V
2.5 V	4.75 V
3.6 V	4.75 V

## 8B. INITIALIZING THE DEVICE

### Introduction

The registers retain data as long as power is applied to the device. The R and N registers contain counter divide ratios for the main loop, PLL. The R' and N' registers contain counter divide ratios for the secondary loop, PLL'. Additional control bits are located in the R', N, and C registers. The D register controls the DACs. Section 8A is a handy reference for register access and bit definitions.

The C, D, R', and N registers can be directly written, and have an immediate impact on chip operation. The Hr and Hn' registers can be directly written, but have no immediate impact on chip operation. This is because the Hr and Hn' registers are the front-ends of double buffers. The Hr register feeds the R register. The Hn' register feeds the N' register. Changing data in the R and/or N' registers is done with a write to the Hr and/or Hn' register, respectively, followed by a write to the N register. The transfer of data from the Hr to R and Hn' to N' registers is triggered with a write to the N register.

Typically, the Hr and Hn' registers are written once, during initialization after power up. The Hr and Hn' registers only need to be accessed if their data is changing.

### An Example

Following is an initialization example for a system with a main loop that covers 1.8 to 2.1 GHz in 30 kHz steps. An external reference of 19.44 MHz is utilized. The secondary loop is selected to run at 200 MHz. Both VCOs are positive polarity meaning that when the input control voltage increases, the output frequency increases. A divided-down reference is not needed ( $f_{out}$  and  $\overline{f_{out}}$ ). Therefore, the Mode pin is tied to  $V_{pos}$  and the Pol and Pol' pins are tied to ground.

The following initialization gives serial data examples for BitGrabber access of the C, Hr, and N registers.

### Initialization

Below is the six-step initialization sequence used after power up for the example given above.

Programming the C register first is recommended if the voltage multiplier is utilized. There are three important criteria to note. Violation of any criterion may cause the voltage multiplier to collapse. The first criterion is that after power up, a sufficient time interval must be provided (after the C and R' registers are initialized) for the on-chip voltage multiplier to build up the voltage on the  $C_{mult}$  pin. This interval is determined by the external capacitor size tied to the  $C_{mult}$  pin and the charging current which is about 100  $\mu$ A. After this interval, the chip can maintain the voltage on the  $C_{mult}$  pin and the phase/frequency detectors for the main loop may be safely activated. The second criterion is that before the phase/frequency detectors are activated, legitimate divide ratios (pertinent to the application) must be loaded in the registers. The third criterion is a hardware issue. The three criteria are discussed with more detail in Section 7E.

If the voltage multiplier is not used, Step 1 is eliminated and the initialization sequence starts with Step 2.

#### Step 1: Load the C Register

The C register is programmed such that the main loop's phase/frequency detector outputs are floating (PD Float bit  $C4 = 1$ ), the reference circuit is active (Osc Stby bit  $C2 = 0$ ),

and an external reference is accommodated (Out B/Xref bit  $C6 = 1$ , with the Mode pin high). When the voltage multiplier is enabled by programming the R' register, the voltage is allowed to build on the  $C_{mult}$  pin such that a voltage higher than the main supply voltage is providing power to the phase/frequency detectors. Both loops are active (PLL Stby bits  $C1 = C0 = 0$ ). Also, for this example, Output A and Output C are programmed low (Out bits  $C7 = C5 = 0$ ).

In summary, hexadecimal 58 or \$58 is serially transferred (BitGrabber access with no address bits).

#### Step 2: Load the R' Register

For the secondary loop, the 19.44 MHz reference is divided down to 80 kHz by the R' counter; the divide ratio is 243. Per Section 8A, the value is doubled to 486. The 16 LSBs of the R' register determine the R' counter divide ratio. Therefore, 486 is converted to \$01E6 and becomes the 16 LSBs (R'15 to R'0) in the R' register. Test/Rst bit R'16 must be a 0. Bits R'19 to R'17 determine the refresh rate of the voltage multiplier. The frequency at  $Osc_e$  is <20 MHz. Therefore, per Section 8A, bits R'19 to R'17 must be 001. If Output A is needed as a MCU port expander, bits R'21 = R'20 = 0. Per Section 8A, Y Coefficient bits R'23 R'22 = 10.

In summary, \$058201E6 is serially transferred (conventional access with an address of 0101).

#### Step 3: Load the Hr Register

For the main loop, the 19.44 MHz reference must be divided down to 30 kHz by the R counter; the divide ratio is 648. Per Section 8A, the ratio 648 is doubled to 1296 and then converted to \$510. The Hr register value is programmed as \$0510. When the Hr register contents are transferred to the R register, the R counter divide ratio is determined.

In summary, \$0510 is serially transferred (BitGrabber access). This value is transferred from the Hr to the R register when the N register is accessed in Step 5.

#### Step 4: Load the Hn' Register

For the secondary loop, the phase detector is chosen to run at 80 kHz. Therefore, 80 kHz must be multiplied up to 200 MHz which is a factor of 2500. The factor is converted to \$9C4. The Hn' register is programmed as \$09C4. When the Hn' register contents are transferred to the N' register, the N' counter divide ratio is determined.

In summary, \$040009C4 is serially transferred (conventional access with an address of 0100). The value \$09C4 is transferred to the N' register when the N register is accessed in Step 5.

#### Step 5: Load the N Register

For this example, the IC is initialized to tune the lowest end of the main loop. The lowest end of the main loop's frequency range is 1.8 GHz. Therefore, the 30 kHz must be multiplied up to 1.8 GHz which is a factor of 60,000 or \$EA60 to be loaded into bits N17 to N0 of the N register. Bit N18 is programmed to 0 for a PD<sub>out</sub>-Hi to PD<sub>out</sub>-Lo current ratio of 4:1. If PD<sub>out</sub>-Lo is used for the main loop, bits N21 to N19 must be 001. (PD<sub>out</sub>-Lo must be used to initialize the device when *adapt* is used, see Section 8D.) Bit N22 = 0 to select a lock detect window of approximately  $32 / Osc_e = 32 / 19.44 \text{ MHz}$  or 1.6  $\mu$ s. Bit N23 must be programmed to 1 by the user. (When the Mode pin is high, programming N23 to a 0 is for Motorola use only.)

In summary, \$88EA60 is serially transferred (BitGrabber access). The N register access also causes double-buffer transfers of Hr to R and Hn' to N'.

### Step 6: Load the C Register

Now that legitimate divide ratios are programmed for the counters, the main loop may be activated. Thus, the PD float bit C4 is now programmed to 0. The standby bits are unchanged: C2 = C1 = C0 = 0. Bit C5 could be used to control Output C to either a low level or high impedance; for a low level, C5 = 0. Whenever an external reference is utilized, bit C6 must be 1. Bit C7 may be used to control Output A to a low or high level because it is selected as "port expander" by bit R'21 and R'20; for a low level, C7 = 0.

In summary, \$40 is serially transferred (BitGrabber access). This causes the main loop to tune to 1.8 GHz, the secondary loop to tune to 200 MHz, and both the Output A and Output C pins to be forced low.

The device is now initialized.

## 8C. PROGRAMMING WITHOUT ADAPT

### Tuning the Top of the Band

After initializing the device via steps 1 through 6 in Section 8B, the only register that needs to be loaded to tune the main loop is the N register.

For this example, tuning the upper end of the band (2.1 GHz) requires that the 30 kHz at the phase/frequency detector be multiplied up to 2.1 GHz. This is a loop multiplying factor of 70,000. This value is converted to \$11170 and is loaded for bits N17 to N0. Bits N23 to N18 are not changed and are programmed as indicated in Section 8B, step 5.

In summary, \$891170 is transferred to tune the main loop. No other registers are loaded.

### Tuning Other Channels

Tuning other channels for the main loop, while keeping the secondary loop at a constant frequency, only requires programming the N register. See Table 22 for example frequencies.

Table 22. Main Loop Tuning Examples

Frequency Desired (MHz)	Multiplying Factor (Decimal)	Multiplying Factor (Hexadecimal)	N Register Data (Hexadecimal)
1800.000	60,000	\$EA60	\$88EA60
1800.030	60,001	\$EA61	\$88EA61

2088.960	69,632	\$11000	\$891000
2100.000	70,000	\$11170	\$891170

## 8D. PROGRAMMING UTILIZING HORSESHOE WITH ADAPT

### Introduction

A unique adapt feature can be used with the MC145225 or MC145230 when conventional tuning cannot meet the lock-time requirements of a system and the annoying spurs or noise cannot be tolerated from a fractional-N scheme. The adapt feature is available on the main loop only.

For adapt, a timer is engaged which causes an internal data update of the R and N registers to be delayed. The IC supports the *Horseshoe* scheme for adapt by allowing a fairly-close quickly-tuned *approximate* frequency to be tuned, followed by the tuning of the *exact* frequency. Two sets of R and N data are sent to the device. The first set {R1, N1} is for tuning the approximate frequency. The second set {R2, N2} is for tuning the exact frequency. Use of the timer delays the transfer of {R2, N2} until a programmed interval has elapsed. In addition, after the interval has elapsed, the main loop control switches from PD<sub>Out</sub>-Hi to PD<sub>Out</sub>-Lo.

### Tuning Near the Top of the Band

Continuing the example, after initializing the device via steps 1 through 6 in Section 8B, Horseshoe with adapt can be used to tune the main loop to obtain fast frequency jumps. Use of the BitGrabber access is recommended to minimize the number of serial data clocks required for sending the four "words".

In this example, the first phase of adapt utilizes approximate tuning with the phase/frequency detector running at 4x the step size. Therefore, the approximate tuning runs the detector at about 120 kHz. The second phase, with exact tuning, runs the detector at 30 kHz. Horseshoe with adapt requires that two data sets be serially sent to the device for every frequency tuned. The first set is for approximate tuning {R1, N1}; the second set is for exact tuning {R2, N2}.

Approximate tuning with Horseshoe is unique. This method involves two key elements: (1) increasing the phase detector frequency and (2) varying *both* the R and N divide values such that the approximate frequency is within a certain predetermined range. The Horseshoe algorithm contained in the development system software also allows placing a constraint on the loop-gain variation that the user can tolerate.

For example, to tune 1800.270 MHz, the first {R1, N1} data set could contain divide ratios for the R and N counters of 138.5 and 12,826, respectively. With this data set, the phase detector is running at about 140 kHz and the approximate frequency is about 325 Hz from the exact frequency. The second data set contains R and N divide ratios of 648 and 60,009, respectively. This achieves the exact (target) frequency of 1800.270 MHz.

The timer must be programmed to determine the interval that the device is in the approximate-tune mode. For this example, assume this is 32 f<sub>R</sub> cycles; thus, bits N21 N20 N19 = 1 0 1 in the first data set. Note that this time interval is 32 cycles of f<sub>R</sub>, with the phase detector running at about 140 kHz (approximate tune) or about 230 μs plus the MCU

## MC145225 MC145230

shift time shown in Figure 64. Included in the first data set are  $N23 = 1$  which is required when the Mode pin is high,  $N22 = 0$  for the lock detect window of  $1.6 \mu\text{s}$ , and  $N18 = 0$  for a current ratio of 4:1 (because the phase detector is running at approximately 4x the step size). Note that bits  $N23$ ,  $N22$ , and  $N18$  are unchanged from the initialization values.

For the second data set, bits  $N23$ ,  $N22$ , and  $N18$  are unchanged. Bits  $N21$ ,  $N20$ , and  $N19$  must be programmed as 001. This enables  $\text{PD}_{\text{Out-Lo}}$  for the exact tune after time out.

In summary, two data sets need to be sent to the device:  $\{R1, N1\}$  and  $\{R2, N2\}$ . They are sent in succession as  $R1$ ,  $N1$ ,  $R2$ ,  $N2$ ; where  $R1$  is the R register value for the first data set,  $N1$  is the N register value for the first set, etc. For the example, these values are  $\{R1, N1\} = \{\$0115, \$A8321A\}$  and  $\{R2, N2\} = \{\$0510, \$88EA69\}$ . See Figure 64.

### Tuning Other Channels

Tuning other channels for the main loop, while keeping the secondary loop at a constant frequency, requires sending two data sets to the part  $\{R1, N1\}$  and  $\{R2, N2\}$ . See Table 23.

## 8E. CONTROLLING THE DACs

### Introduction

The two 8-bit DACs are independent circuit blocks on the chip. They have no interaction with other circuits on the chip. A single 16-bit register, called the D register, holds the binary value which controls both DACs.

### Programming the DACs

A DAC programmed for 0 scale is in the low-power mode. The 0 scale is programmed as  $\$00$  for each 8-bit DAC.

As an example, consider a system that uses just one of the DACs (DAC 1). The other DAC output is unused and is programmed for 0 output. If a condition for a system requires that the DAC have a half-scale output, then DAC 1 is programmed as  $\$80$ .

In summary,  $\$03000080$  is serially transferred (conventional access with an address of 0011).

**Table 23. Main Loop Tuning Using Horseshoe With Adapt**

Desired Target Frequency (MHz)	Approximate Tuning			Exact Tuning	
	R1	N1	Frequency Error (Hz)	R2	N2
1800.000	$\$0144$	$\$A83A98$	0	$\$0510$	$\$88EA60$
1800.270	$\$0115$	$\$A8321A$	325	$\$0510$	$\$88EA69$

## 9. APPLICATION CIRCUIT

Figure 65. Application Circuit

- NOTES:**
1. R should be chosen to achieve the desired isolation. Use of a capacitor in place of R is possible, but there is the possibility of phase locking on VCO harmonics if they fall on the high-sensitivity point of the  $f_{in}$  or  $f_{in}'$  input. This is because use of a capacitor in place of R forms a high-pass filter.
  2.  $V_{pos}$  may range from 1.8 to 3.6 V.
  3. DAC power may be any potential between 1.8 V and 3.6 V.
  4. Configurable pins. See Pin Descriptions.
  5. Tie mode to Gnd or  $V_{pos}$ .

**MC145220EVK**

*Technical Summary*  
**MC145220 Evaluation Board**

**INTRODUCTION**

The MC145220EVK makes it easy to exercise features of the MC145220 and build PLLs which meet individual performance requirements. The EVK is controlled through menu driven software operating on an IBM PC or compatible. Other Motorola PLL EVKs (MC145190, MC145191, MC145192, MC145200, MC145201, MC145202) in up to three-board cascades can use the same program. Frequency defaults that apply to each are automatically selected. All board functions are controlled through the printer port of an IBM PC. Up to three different EVKs may be controlled at the same time from one printer port. The functional block diagram is given in Figure 1.

This technical summary contains the hardware description for the evaluation board and a summary of the software section. For complete information, consult the manual that is provided in the evaluation kit.

**ORDERING INFORMATION**

These kits may be ordered through your local Motorola Semiconductor sales office or authorized distributor. Ask your Motorola representative to order the kits from the finished goods warehouse, not the literature distribution center. Request the part number shown below.

<b>Part Number</b>	<b>Description</b>
MC145220EVK	Kit with the MC145220 installed.

This document contains information on a new product. Specifications and information herein are subject to change without notice.

# SECTION 1 – HARDWARE

## FEATURES

1. The EVK is a complete working synthesizer, including VCOs.
2. Board is controlled by an IBM PC-compatible computer through the printer port.
3. Up to three boards can be operated independently through one printer port.
4. A prototype area and mounting holes are provided for VCOs, mixers, and amplifiers.
5. External reference input can be used.
6. Five element loop filter is included.
7. Frequency range of operation, step size and reference frequency can be changed in the control program.
8. Lock Detect, Out A, and Out B on any single board are accessible through the printer port.

## CONTENTS OF EVALUATION KIT

1. Assembled evaluation board.
2. Nine-foot flat cable with four DB-25 male connectors.
3. MC145220EVK manual.
4. 3.5" PC-compatible disk containing compiled program.
5. PLL device data sheets.

## GETTING STARTED

To perform basic functions, do the following:

1. Plug in 12 volts at J8, observing the polarity marked on the board.
2. Short circuit section 1 of the DIP switch (S1) and open circuit all other sections.
3. Connect the supplied flat cable between the computer printer port and the DB-25 connector on the board (J9).
4. Type PLL at the DOS prompt. Then press enter.
5. Type the number that corresponds with the type of board given in the on-screen menu. The MC145220 may operate in single loop or dual loop mode. Then press Q.

You should now see the main menu displayed. There should be a signal present at J5 if single loop, or J12 if dual loop. The frequency will be the current output frequency given in the main menu. If the signal is not on the correct frequency, check to see if your printer port address is \$278 (hexadecimal 278). If not, then select the P menu item and enter the correct address. After returning to the main menu, select the I menu item to send data to the board. You should now be on frequency.

## MODIFICATIONS

The user may modify the hardware, such as utilizing a different VCO, by using the prototyping area of the board. After such modifications are made, the default values in the software may need to be changed. This is facilitated from the 'Select from the available options' screen.

Note that the on-board voltage regulators allow for a maximum VCO control voltage range of 0.5 – 4.5 volts.

Figure 1. Evaluation Kit Block Diagram

## TYPICAL PERFORMANCE

Typical performance applies only to the configuration as shipped. The MC145220EVK is shipped with  $V+ = 5$  V. For lowest phase noise in single or dual loop mode, a  $50 \Omega$  load must be connected to J12.

	Single Loop PLL	Single Loop PLL'	Dual Loop PLL
Supply Voltage (J8)	11.5 – 12.5 V		
Supply Current (J8) (Note 1)	177 mA		
Available Current (Note 2)	45 mA		
Frequency Range (Note 3)	733 – 743 MHz	790 – 820 MHz	60 – 80 MHz
Reference Frequency (M1)	10.01 MHz		
Temperature Stability (M1, – 30°C to + 70°C)	< $\pm 2.5$ ppm		
Reference Frequency (M5)	14.4 MHz		N/A
Temperature Stability (M5, – 30°C to + 85°C)	< $\pm 2$ ppm		N/A
TCXO Aging (M1, M5)	< $\pm 1$ ppm / year		
Step Size	10 kHz		10 Hz
Power Output	– 3.0 dBm	– 5.0 dBm	4.5 – 7.5 dBm
Frequency Accuracy	$\pm 1.5$ kHz	$\pm 1.5$ kHz	$\pm 50$ Hz
Reference Sidebands (Note 4)	– 57 dB	– 74 dB	– 57 dB
Phase Noise (100 Hz)	– 65 dBc/Hz	– 56 dBc/Hz	– 50 dBc/Hz
Phase Noise (10 kHz) (Note 5)	– 104 dBc/Hz	– 90 dBc/Hz	– 89 dBc/Hz
Switching Time (Note 6)	24 ms	40 ms	45 ms

### NOTES:

- Supply current is current the board requires without user modifications.
- Available current is the sum of currents available to the user (in the prototype area) from the 5 V and 8.5 V supply. The 12 V supply is not regulated. Current at 12 V is limited by the external power supply. If the on-board VCO and amplifier are disconnected from the power bus, more current can be drawn in the prototype area. The current flowing into U5 (the 8.5 V regulator) should not exceed 180 mA. This will limit temperature rise in U5.
- Frequency ranges require use of the 5 V default charge pump supply voltage.
- VCO sidebands on PLL at low step sizes (10 kHz) are limited by control line leakage of the VCO. Up to 24 nA of leakage has been seen. At higher step sizes (100 kHz and above), this effect is much less noticeable. This did not affect PLL' because its VCO leakage was less than 10 pA.
- 10 kHz phase noise is limited by the PLL device noise. For low noise designs, the loop bandwidth is made narrower and the VCO is relied upon to provide the 10 kHz phase noise. This can be seen on the EVKs since the VCOs have much lower noise.
- 10 MHz step, within  $\pm 1$  kHz of final frequency ('220).  
Due to the software architecture, when the user is measuring the switching time of a single board in dual loop mode, it takes 20 ms to load the data as compared to single loop mode, which takes 8 ms to load the data. This is a limitation of the software, not the IC.  
To find the actual PLL switching time, subtract 8 or 20 ms from the switching time stated in the table.

## SUPPORT MATERIAL

The following documents are included in the appendix:

1. Schematic diagram of MC145220EVK.
2. Bill of materials.
3. Parts layout diagram.
4. Mechanical drawing of board.
5. MC145220 data sheet.
6. Typical signal plots.

## PRODUCTION TEST

After assembly is complete, the following alignment and test is performed:

1. The control program is started in '220 single loop mode.
2. [L]! is selected to set PLL frequency to 733 MHz.
3. Power is applied to the board. DIP switch section 1 is closed circuit with all others being open circuit.
4. After attaching computer cable, [I]! is selected.
5. Trim resistor VR1 is adjusted to obtain an output frequency at J5 of 733 MHz  $\pm$  500 Hz.
6. Voltage at the control voltage test point (TP2) is measured. It must be  $> 0.5$  V.
7. [H]! is selected.
8. Voltage at the control voltage test point (TP2) is measured. It must be  $< 4.4$  V.
9. [T]! is selected to toggle to PLL'.
10. [L]! is selected to set PLL' frequency to 790 MHz.
11. Voltage at the control voltage test point (TP9) is measured. It must be  $> 0.5$  V.
12. [H]! is selected to set PLL' frequency to 820 MHz.
13. Voltage at the control voltage test point (TP9) is measured. It must be  $< 4.4$  V.
14. [G] is selected and the board type is changed to '220 dual loop mode.
15. [Q]!, then [I]!, is selected to initialize the dual mode output (J12) to 70 MHz. The frequency should be 70 MHz  $\pm$  50 Hz.

If in step 5 it isn't possible to obtain a signal on frequency, the adjustment screw in M1 may be turned for further frequency adjustment range. If neither adjustment works, [P] should be selected and the correct printer port address entered. [I]! is then selected to reload the data.

## BOARD OPERATION

A computer is connected to the DB-25 connector J9. Data is output from the printer port. The printer card is in slot 0 using the default address in the control program. Data is sent to the PLL device (U1) through the DIP switch (S1), and 74HCT241 buffer (U2). D1, D2, D3, R7, R8, and R12 are in the data path between the 'HCT241 and PLL device. This limits the high level output voltage of the buffer. Voltage on PLL device inputs must be no greater than 0.5 V above V+. A '220 PLL has three output lines which are routed through a 74LS126 line driver (U3) back to the computer.

U2, the 74HCT241, provides isolation and logic translation for PLL input lines. Logic translation is needed from the TTL levels on the printer port to the CMOS levels on the '220 inputs.

A 12 V power supply should be used to power the board at J8 (Augat 2SV-02 connector). The 2SV-02 will accept 18-24 AWG bare copper power leads. No tools are needed for connection. If power is properly connected, LED D4 will be lit.

Power passes from J8 to U5 (LM317 regulator) configured as an 8.5 V regulator. 8.5 V powers the VCOs. Regulators U6 and U7 use the 8.5 V supply to produce 3 V and 5 V. The '220 board can use either to power the logic and charge pump. V+ voltage is selected by J11. U6 and U7 are cascaded with U5 to equalize their individual voltage drops.

The '220 operates in both a single loop and dual loop mode. There are no component changes between the two modes. The differences are in the programming of the counters and the SMA connector that is used.

The PLL loop is composed of the MC145220 (U1), 733 – 743 MHz VCO (M2), and a passive loop filter (R4, R5, C6, C7, C8). In single loop mode, output is taken from J5. A passive loop filter was used to keep the design simple, reduce noise, and reduce the quantity of traces susceptible to stray pickup. The PLL' loop is composed of the MC145220 (U1), 790 – 820 MHz VCO (M3), and a passive loop filter (R22, R25, C24, C26, C30). In single loop mode, output is taken from J10.

Dual mode output is the  $(f' - f)$  frequency output from the mixer. It is low pass filtered (L1, L2, C15, C21, C22) then amplified (U4). The output is available at J12.

Phase detector current is 2 mA. J1 is a removable jumper used for current measurement of V+.

Two TCXOs, a Motorola Saber 14.4 MHz (M5), and Raltron 10.01 MHz (M1) are supplied. As shipped from the factory, the 10.01 MHz TCXO is in use. This allows both the 10 kHz and 10 Hz step sizes to be used with one TCXO. 10.01 MHz cannot be divided for larger step sizes such as 100 kHz. For larger step sizes use the Saber. Jumpers J3, J4, J13, and J14 determine which TCXO or the external reference input is in use.

## DUAL MODE OUTPUT

The dual mode output (J12) is the difference frequency from mixing PLL and PLL'. By using a reference frequency of 10.01 MHz, PLL can be operated with a 10.01 kHz step size and PLL' with a 10 kHz step size. If both PLL and PLL' step down in frequency, the mixed output will step up by 10 Hz. More information on the offset reference technique is in **AN1277/D, Offset Reference PLLs for Fine Resolution or Fast Hopping**. The block diagram, formulas, and an example are shown in Figure 2.

Figure 2. Dual Mode Block Diagram

PLL	PLL'
$f = N (10.01 \text{ kHz})$	$f' = N' (10 \text{ kHz})$
$f = 10.01 \text{ kHz} \left[ 74,000 - \frac{r(f' - f)}{10 \text{ Hz}} \right]$	$f' = 10 \text{ kHz} \left[ \frac{w(f' - f) + 740 \text{ kHz}}{10 \text{ kHz}} + N \right]$
$N = 74,000 - \frac{r(f' - f)}{10 \text{ Hz}}$	$N' = N + 74 + \frac{w(f' - f)}{10 \text{ kHz}}$
$(f' - f) = w(f' - f) + r(f' - f)$	
$(f' - f) = \text{Desired Output Frequency}$	
$w(f' - f) = \text{Output Frequency Portion that Divides Evenly by 10 kHz}$	
$r(f' - f) = \text{Remainder from Output Frequency Division by 10 kHz}$	

### Dual Mode Formulas

#### Example: Synthesize 76.849 930 MHz

$$r(f' - f) = 9.930 \text{ kHz},$$

$$w(f' - f) = 76.840 \text{ MHz}$$

$$N = 74,000 - \frac{9.930 \text{ kHz}}{10 \text{ Hz}} = 73,007$$

$$f = 73,007 (10.01 \text{ kHz}) = 730.800 070 \text{ MHz}$$

$$N' = 73,007 + 74 + \frac{76.840 \text{ MHz}}{10 \text{ kHz}} = 80,765$$

$$f' = 80,765 (10 \text{ kHz}) = 807.650 000 \text{ MHz}$$

$$(f' - f) = 807.650 000 \text{ MHz} - 730.800 070 \text{ MHz} = 76.849 930 \text{ MHz}$$

## EXTERNAL REFERENCE INPUT

To use an external reference, disconnect J3, J4, J13, and J14. Use a reference signal at J2 which complies with data sheet requirements. Then modify the reference frequency in the program main menu to reflect the changes made (F menu item).

## DATA TRANSFER FROM COMPUTER TO EVK

To control the serial input EVK with the parallel printer port, a conversion is done. Printer cards are designed to output eight bits through eight lines. A bit mask is used to obtain the bit combination for the three required output lines (Data, Clock, Load). As bytes are sent to the printer card in sequence, it appears to be a serial transfer. The printer port is used because data transfer using the serial port would be much slower. A standard IBM PC can support a parallel port data rate of 4.77 MHz.

IBM PCs and compatibles can accept up to three printer port configurations. These ports are called LPT1, LPT2, and LPT3. Each printer port has a unique address. Two sets of addresses are in common use. One set applies to IBM PC XT, AT, and clones. The other is for the PS 2 line. To load data into the EVK, the correct address must be selected. The program default is \$278. If \$278 is not the address in use, it must be modified by entering the P menu item in the main menu. All allowed addresses given in hexadecimal are as follows:

Label	IBM PC and Clones	PS 2
LPT1	278	3BC
LPT2	378	378
LPT3	3BC	278

Up to three EVK boards can operate independently from one printer port. All lines on the printer port are connected to every EVK. Even with three boards operating, only three output lines (Clock, Data, and Load) from the printer card are used. If two boards are controlled together, data for the second board is received from the Output A of the first. Output A is a configurable output on '220 devices, which in this case is used to shift data through chip 1 into chip 2. Output A and Data are connected using a printer port input line. This was done to avoid connecting extra wires. Fortunately not all port input lines are needed for computer input. Load and Clock are common to both boards.

A three-board cascade is handled similarly to a two-board cascade. Out A on the first board is fed to Data on the second. Out A on the second connects to Data on the third. Instructing the program on the quantity of boards connected together allows it to modify the number of bits sent.

All boards have a DIP switch S1 which gives each a unique address. The configuration menu is used to tell the program what type of board is connected at a board address. Switch positions for all possible addresses are given in Figure 2.

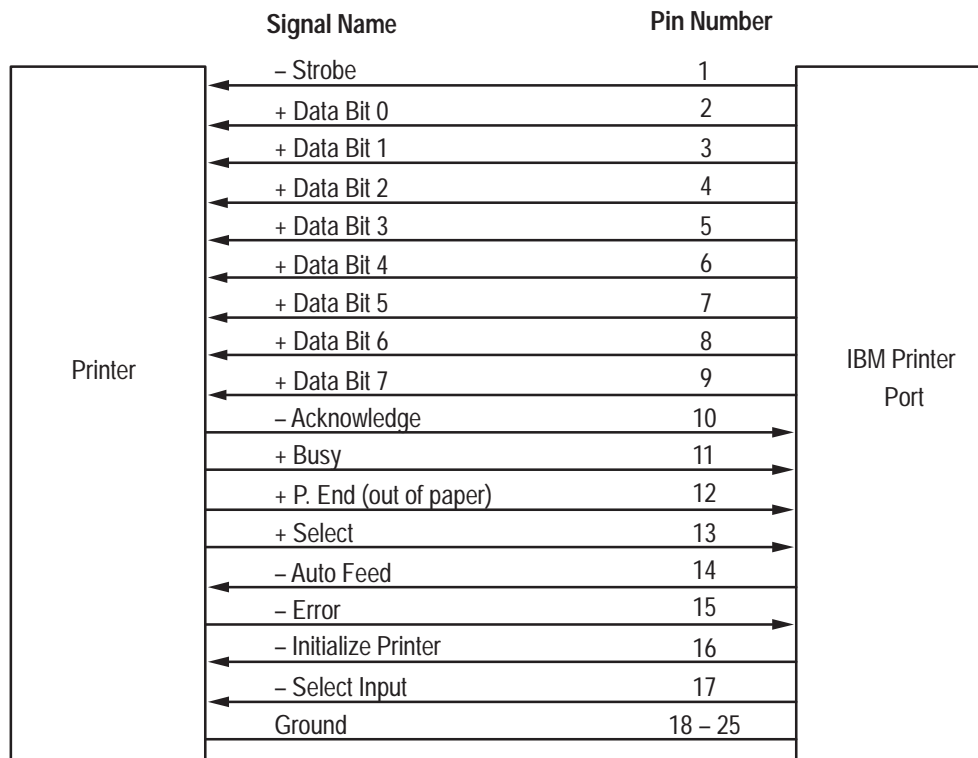

**Figure 3. Switch Positions**

In Figure 2, DIP switch sections 6, 7, and 8 allow the computer to read Out A, Lock Detect, or Lock Detect from the PLL device. Each of the inputs can only be read on one board at a time, but each item could be read on a different board. In a three-board cascade, Out A could be read from the first board, Out B from the second, and Lock Detect from the third. There is no way to determine the board address of a particular input with software. The control program does not make use of these inputs; however, source code could be modified as required. Pin assignment on the printer port connector is:

Label	Pin Number
Out A	12
Out B	13
Lock Detect	15

## PRINTER PORT CONFIGURATION

Printer port outputs on an IBM PC or clone use TTL–LS logic levels. Inputs are one TTL–LS load. Signal lines can be used for any purpose. The standard names, direction of data flow, true and inverted data are shown in Figure 3.

**Figure 4. Printer Port Data Lines**

Pin numbers for the port connector are shown in Figure 4.

**Figure 5. DB–25 Male Connector**

## SECTION 2 – SOFTWARE DESCRIPTIONS SUMMARY

### INTRODUCTION

The MC145xxx EVK control program is used to program all PLL evaluation kits. It will simultaneously control up to three different boards independently from one printer port. All features of the PLL device may be accessed. Default frequencies can be modified to allow use of different channel spacings and VCOs.

User input errors are detected and appropriate messages are displayed.

To show the format of the program, a sample screen is shown below:

## Motorola RF Discrete Transistors

Motorola offers the most extensive group of RF Discrete Transistors offered by any semiconductor manufacturer anywhere in the world today.

From Bipolar to FET, from Low Power to High Power, the user can choose from a variety of packages. They include plastic and ceramic that are microstrip circuit compatible or surface mountable. Many are designed for automated assembly equipment.

Major sub-headings are Small Signal, Medium Power, Power MOSFETs and Bipolar Transistors.

# Motorola RF Small Signal Transistors

Motorola's broad line of RF Small Signal Transistors includes NPN Silicon Bipolar Transistors characterized for low noise amplifiers, mixers, oscillators, multipliers, non-saturated switches and low-power drivers.

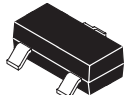

These devices are available in a variety of package types. Most of these transistors are fully characterized with s-parameters.

# Motorola RF Medium Power Transistors

RF Medium Power Transistors are used in portable transmitter applications and low voltage drivers for higher power devices. They can be used for analog cellular, GSM and the newer digital handheld cellular phones. GaAs, LDMOS and Bipolar devices are available. RF Medium Power Transistors are supplied in Motorola's high performance PLD line of surface mount power RF packages. Other applications include talkback pagers, wireless modems and LANs, cable modems, highspeed drivers and instrumentation.

# Motorola RF High Power Transistors

## RF Power MOSFETs

Motorola RF Power MOSFETs are constructed using a planar process to enhance manufacturing repeatability. They are *N-channel field effect transistors* with an oxide insulated gate which controls vertical current flow.

Compared with bipolar transistors, RF Power FETs exhibit higher gain, higher input impedance, enhanced thermal stability and lower noise. The FETs listed in this section are specified for operation in RF Power Amplifiers and are grouped by frequency range of operation and type of application. Arrangement within each group is first by order of voltage then by increasing output power.

**Table 1. 2 to 150 MHz HF/SSB – Vertical MOSFETs**

For military and commercial HF/SSB fixed, mobile and marine transmitters.

Device	Frequency Band <sup>(37)</sup>		P <sub>out</sub> Watts	Gain (Typ) @ 30 MHz dB	Typical IMD		θ <sub>JC</sub> °C/W	Package/Style

# RF Power Bipolar Transistors

Motorola's broad line of bipolar RF power transistors are characterized for operation in RF power amplifiers. Typical applications are in base stations, military and commercial landmobile, avionics and marine radio transmitters. Groupings are by frequency band and type of application. Within each group, the arrangement of devices is by major supply voltage rating, then in the order of increasing output power. All devices are NPN polarity except where otherwise noted.

## UHF Transistors

<sup>(3)</sup>Internal Impedance Matched Push-Pull Transistors

<sup>(37)</sup>M = Matched Frequency Band; U = Unmatched Frequency Band.

## Microwave Transistors

**Table 4. L-Band Long Pulse Power**

These products are designed for pulse power amplifier applications in the 960–1215 MHz frequency range. They are capable of handling up to 10  $\mu$ s pulses in long pulse trains resulting in up to a 50% duty cycle over a 3.5 millisecond interval. Overall duty cycle is limited to 25% maximum. The primary applications for devices of this type are military systems, specifically JTIDS and commercial systems, specifically Mode S. Package types are hermetic.

Device	Frequency Band <sup>(37)</sup>	P <sub>out</sub> Watts	Gain (Min) @ 1215 MHz dB	$\theta_{JC}$ °C/W	Package/Style

## Linear Transistors

The following sections describe a wide variety of devices specifically characterized for linear amplification. Included are medium power and high power parts covering frequencies to 2.0 GHz.

**Table 5. UHF Ultra Linear For TV Applications**

The following device has been characterized for ultra-linear applications such as low-power TV transmitters in Band IV and Band V and features diffused ballast resistors and an all-gold metal system to provide enhanced reliability and ruggedness.

Device	Frequency Band <sup>(37)</sup>	P <sub>out</sub> Watts	Gain (Typ)/Freq. Small Signal Gain dB/MHz	$\theta_{JC}$ °C/W	Package/Style
<b>V<sub>CC</sub> = 28 Volts, Class AB</b>					
TPV8100B	M 470–860	100 <sup>(11)</sup>	9.5/860	0.7	398/1

**Table 6. Microwave Linear for PCN Applications**

The following devices have been developed for linear amplifiers in the 1.5–2 GHz region and have characteristics particularly suitable for PDC, PCS or DCS1800 base station applications.

Device	Frequency Band <sup>(37)</sup>	P <sub>out</sub> Watts	Class	Gain (Typ)/Freq. dB/MHz	$\theta_{JC}$ °C/W	Package/Style
<b>V<sub>CC</sub> = 26 Volts–Bipolar Die</b>						
MRF6404 <sup>(16)</sup>	M 1860–1900	30	AB	8.2/1880	1.4	395C/1
MRF20030R	M 2000	30	AB	11/2000	1.4	395C/1
MRF20060R	M 2000	60	AB	9.8/2000	0.7	451/1
MRF20060RS	M 2000	60	AB	9.8/2000	0.7	451A/1

<sup>(7)</sup>Typical @ 1090 MHz

<sup>(11)</sup>Output power (Min) at 1 dB compression in Class AB

<sup>(16)</sup>Formerly known as "TP4035"

<sup>(37)</sup>M = Matched Frequency Band; U = Unmatched Frequency Band.

The RF Line  
**NPN Silicon**  
**Low Noise, High-Frequency**  
**Transistors**

Designed for use in high gain, low noise small-signal amplifiers. This series features excellent broadband linearity and is offered in a variety of packages.

- Fully Implanted Base and Emitter Structure
- 9 Finger, 1.25 Micron Geometry with Gold Top Metal
- Gold Sintered Back Metal
- Available in tape and reel packaging options:
  - T1 suffix = 3,000 units per reel
  - T3 suffix = 10,000 units per reel

**MMBR941**  
**MRF947**

## MAXIMUM RATINGS

Rating	Symbol	MMBR941LT1, T3	MRF947 Series	Unit
Collector–Emitter Voltage	$V_{CEO}$	10	10	Vdc
Collector–Base Voltage	$V_{CBO}$	20	20	Vdc
Emitter–Base Voltage	$V_{EBO}$	1.5	1.5	Vdc
Power Dissipation (1) $T_C = 75^\circ\text{C}$ Derate linearly above $T_{\text{case}} = 75^\circ\text{C}$ @	$P_{D\text{max}}$	0.25 3.33	0.188 2.5	Watts mW/°C
Collector Current — Continuous (2)	$I_C$	50	50	mA
Maximum Junction Temperature	$T_{J\text{max}}$	150	150	°C
Storage Temperature	$T_{\text{stg}}$	–55 to +150	–55 to +150	°C
Thermal Resistance, Junction to Case	$R_{\theta\text{JC}}$	300	400	°C/W

## DEVICE MARKING

MMBR941LT1 = 7Y MRF947AT1 = G	MMBR941BLT1 = 7N	MRF947T1, T3 = A	MRF947BT1 = H
----------------------------------	------------------	------------------	---------------

## ELECTRICAL CHARACTERISTICS ( $T_A = 25^\circ\text{C}$ unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
----------------	--------	-----	-----	-----	------

### OFF CHARACTERISTICS (3)

Collector–Emitter Breakdown Voltage ( $I_C = 0.1\text{ mA}$ , $I_B = 0$ )	All	$V_{(\text{BR})\text{CEO}}$	10	12	—	Vdc
Collector–Base Breakdown Voltage ( $I_C = 0.1\text{ mA}$ , $I_E = 0$ )	All	$V_{(\text{BR})\text{CBO}}$	20	23	—	Vdc
Emitter Cutoff Current ( $V_{EB} = 1.0\text{ V}$ , $I_C = 0$ )	All	$I_{EBO}$	—	—	0.1	$\mu\text{Adc}$
Collector Cutoff Current ( $V_{CB} = 10\text{ V}$ , $I_E = 0$ )	All	$I_{CBO}$	—	—	0.1	$\mu\text{Adc}$

### ON CHARACTERISTICS (3)

DC Current Gain ( $V_{CE} = 6.0\text{ V}$ , $I_C = 5.0\text{ mA}$ ) (MMBR941LT1) (MMBR941BLT1)		$h_{FE}$	50 100	— —	200 200	—
DC Current Gain ( $V_{CE} = 1.0\text{ V}$ , $I_C = 500\text{ }\mu\text{A}$ )	MRF947T1, MRF947BT1	$h_{FE1}$	50	—	—	—
DC Current Gain ( $V_{CE} = 6.0\text{ V}$ , $I_C = 5.0\text{ mA}$ )	MRF947T1, T3 MRF947AT1 MRF947BT1	$h_{FE2}$ $h_{FE3}$ $h_{FE4}$	50 75 100	— — —	— 150 200	—

### DYNAMIC CHARACTERISTICS

Collector–Base Capacitance ( $V_{CB} = 10\text{ V}$ , $I_E = 0$ , $f = 1.0\text{ MHz}$ )	All	$C_{cb}$	—	0.35	—	pF
Current Gain — Bandwidth Product ( $V_{CE} = 6.0\text{ V}$ , $I_C = 15\text{ mA}$ , $f = 1.0\text{ GHz}$ )	All	$f_T$	—	8.0	—	GHz

#### NOTE:

- To calculate the junction temperature use  $T_J = P_D \times R_{\theta\text{JC}} + T_{\text{CASE}}$ . Case temperature measured on collector lead immediately adjacent to body of package.
- $I_C$  — Continuous (MTBF  $\approx 10$  years).
- Pulse width  $\leq 300\text{ }\mu\text{s}$ , duty cycle  $\leq 2\%$  pulsed.

**PERFORMANCE CHARACTERISTICS**

Conditions	Symbol	MMBR941LT1, T3			MRF947 Series			Unit
		Min	Typ	Max	Min	Typ	Max	
Insertion Gain ( $V_{CE} = 6.0\text{ V}$ , $I_C = 15\text{ mA}$ , $f = 1.0\text{ GHz}$ ) ( $V_{CE} = 6.0\text{ V}$ , $I_C = 15\text{ mA}$ , $f = 2.0\text{ GHz}$ )	$ S_{21} ^2$	—	14	—	—	14	—	dB
Maximum Unilateral Gain (1) ( $V_{CE} = 6.0\text{ V}$ , $I_C = 15\text{ mA}$ , $f = 1.0\text{ GHz}$ ) ( $V_{CE} = 6.0\text{ V}$ , $I_C = 15\text{ mA}$ , $f = 2.0\text{ GHz}$ )	$G_{U\text{ max}}$	—	16	—	—	14.8	—	dB
Noise Figure — Minimum (Figure 9) ( $V_{CE} = 6.0\text{ V}$ , $I_C = 5.0\text{ mA}$ , $f = 1.0\text{ GHz}$ ) ( $V_{CE} = 6.0\text{ V}$ , $I_C = 5.0\text{ mA}$ , $f = 2.0\text{ GHz}$ )	$NF_{\text{MIN}}$	—	1.5	—	—	1.5	—	dB
Associated Gain at Minimum NF (Figure 9) ( $V_{CE} = 6.0\text{ V}$ , $I_C = 5.0\text{ mA}$ , $f = 1.0\text{ GHz}$ ) ( $V_{CE} = 6.0\text{ V}$ , $I_C = 5.0\text{ mA}$ , $f = 2.0\text{ GHz}$ )	$G_{\text{NF}}$	—	14	—	—	14	—	dB
Noise Figure — 50 ohm Source ( $V_{CE} = 6.0\text{ V}$ , $I_C = 5.0\text{ mA}$ , $f = 1.0\text{ GHz}$ )	$NF_{50\ \Omega}$	—	1.9	2.8	—	1.9	2.8	dB

NOTE:

1. Maximum Unilateral Gain is  $G_{U\text{ max}} = \frac{|S_{21}|^2}{(1-|S_{11}|^2)(1-|S_{22}|^2)}$

The RF Line  
**NPN Silicon**  
**Low Noise, High-Frequency**  
**Transistors**

Designed for use in high gain, low noise small-signal amplifiers. This series features excellent broadband linearity and is offered in a variety of packages.

- Fully Implanted Base and Emitter Structure
- 18 Finger, 1.25 Micron Geometry with Gold Top Metal
- Gold Sintered Back Metal
- Available in tape and reel packaging options:  
    T1 suffix = 3,000 units per reel

Storage Temperature	$T_{\text{stg}}$	–55 to +150	–55 to +150	°C
Thermal Resistance, Junction to Case	$R_{\theta\text{JC}}$	233	330	°C/W

**DEVICE MARKING**

MMBR951LT1 = 7Z      MRF957T1 = B

**ELECTRICAL CHARACTERISTICS** ( $T_A = 25^\circ\text{C}$  unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
----------------	--------	-----	-----	-----	------

**OFF CHARACTERISTICS** (3)

Collector–Emitter Breakdown Voltage ( $I_C = 0.1\text{ mA}$ , $I_B = 0$ )	$V_{(\text{BR})\text{CEO}}$	10	13	—	Vdc
Collector–Base Breakdown Voltage ( $I_C = 0.1\text{ mA}$ , $I_E = 0$ )	$V_{(\text{BR})\text{CBO}}$	20	25	—	Vdc
Emitter Cutoff Current ( $V_{EB} = 1.0\text{ V}$ , $I_C = 0$ )	$I_{EBO}$	—	—	0.1	$\mu\text{Adc}$
Collector Cutoff Current ( $V_{CB} = 10\text{ V}$ , $I_E = 0$ )	$I_{CBO}$	—	—	0.1	$\mu\text{Adc}$

**ON CHARACTERISTICS** (3)

DC Current Gain ( $V_{CE} = 6.0\text{ V}$ , $I_C = 5.0\text{ mA}$ )	$h_{FE}$	50	—	200	—
--	----------	----	---	-----	---

**DYNAMIC CHARACTERISTICS**

Collector–Base Capacitance ( $V_{CB} = 10\text{ V}$ , $I_E = 0$ , $f = 1.0\text{ MHz}$ )	$C_{cb}$	—	0.45	1.0	pF
Current Gain — Bandwidth Product ( $V_{CE} = 6.0\text{ V}$ , $I_C = 30\text{ mA}$ , $f = 1.0\text{ GHz}$ )	$f_T$	—	8.0	—	GHz
		—	9.0	—	

**NOTES:**

- To calculate the junction temperature use  $T_J = (P_D \times R_{\theta\text{JA}}) + T_{\text{CASE}}$ . Case temperature measured on collector lead immediately adjacent to body of package.
- $I_C$  — Continuous (MTBF  $\approx 10$  years).
- Pulse width  $\leq 300\ \mu\text{s}$ , duty cycle  $\leq 2\%$  pulsed.

**PERFORMANCE CHARACTERISTICS**

Conditions	Symbol	MMBR951LT1			MRF957T1			Unit
		Min	Typ	Max	Min	Typ	Max	
Insertion Gain (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 30 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 30 mA, f = 2.0 GHz) (V <sub>CE</sub> = 5.0 V, I <sub>C</sub> = 30 mA, f = 1.5 GHz)	S <sub>21</sub>   <sup>2</sup>	—	12.5	—	—	13.3	—	dB
Maximum Unilateral Gain (1) (V <sub>CE</sub> = 8.0 V, I <sub>C</sub> = 30 mA, f = 1.0 GHz) (V <sub>CE</sub> = 8.0 V, I <sub>C</sub> = 30 mA, f = 2.0 GHz) (V <sub>CE</sub> = 5.0 V, I <sub>C</sub> = 30 mA, f = 1.5 GHz)	GU <sub>max</sub>	—	14	—	—	14	—	dB
Noise Figure — Minimum (Figure 9) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 2.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.5 GHz)	NF <sub>MIN</sub>	—	1.3	—	—	1.5	—	dB
Associated Gain at Minimum NF (Figure 9) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 2.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.5 GHz)	G <sub>NF</sub>	—	13	—	—	11.8	—	dB
Noise Figure — 50 ohm Source (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz)	NF <sub>50 Ω</sub>	—	1.9	2.8	—	1.9	2.8	dB

NOTE:

$$1. \text{ Maximum Unilateral Gain is } GU_{\max} = \frac{|S_{21}|^2}{(1 - |S_{11}|^2)(1 - |S_{22}|^2)}$$

Table 3. MRF957T1 Typical Common Emitter S-Parameters (continued)

The RF MOSFET Line  
**RF Power Field-Effect Transistor**  
N-Channel Enhancement-Mode

. . . designed for wideband large-signal amplifier and oscillator applications up to 400 MHz range.

- Guaranteed 28 Volt, 150 MHz Performance  
Output Power = 5.0 Watts  
Minimum Gain = 11 dB  
Efficiency — 55% (Typical)
- Small-Signal and Large-Signal Characterization
- Typical Performance at 400 MHz, 28 Vdc, 5.0 W  
Output = 10.6 dB Gain
- 100% Tested For Load Mismatch At All Phase Angles  
With 30:1 VSWR
- Low Noise Figure — 2.0 dB (Typ) at 200 mA, 150 MHz
- Excellent Thermal Stability, Ideally Suited For Class A Operation

**MRF134**

**5.0 W, to 400 MHz  
N-CHANNEL MOS  
BROADBAND RF POWER  
FET**

**CASE 211-07, STYLE 2**

**MAXIMUM RATINGS**

Rating	Symbol	Value	Unit
Drain-Source Voltage	$V_{DSS}$	65	Vdc
Drain-Gate Voltage ( $R_{GS} = 1.0\text{ M}\Omega$ )	$V_{DGR}$	65	Vdc
Gate-Source Voltage	$V_{GS}$	$\pm 40$	Vdc
Drain Current — Continuous	$I_D$	0.9	Adc
Total Device Dissipation @ $T_C = 25^\circ\text{C}$ Derate above $25^\circ\text{C}$	$P_D$	17.5 0.1	Watts W/ $^\circ\text{C}$
Storage Temperature Range	$T_{stg}$	-65 to +150	$^\circ\text{C}$

**THERMAL CHARACTERISTICS**

Rating	Symbol	Value	Unit
Thermal Resistance, Junction to Case	$R_{\theta JC}$	10	$^\circ\text{C/W}$

**Handling and Packaging** — MOS devices are susceptible to damage from electrostatic charge. Reasonable precautions in handling and packaging MOS devices should be observed.

**ELECTRICAL CHARACTERISTICS** ( $T_C = 25^\circ\text{C}$  unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
----------------	--------	-----	-----	-----	------

**OFF CHARACTERISTICS**

Drain–Source Breakdown Voltage ( $V_{GS} = 0, I_D = 5.0 \text{ mA}$ )	$V_{(BR)DSS}$	65	—	—	Vdc
Zero Gate Voltage Drain Current ( $V_{DS} = 28 \text{ V}, V_{GS} = 0$ )	$I_{DSS}$	—	—	1.0	mAdc
Gate–Source Leakage Current ( $V_{GS} = 20 \text{ V}, V_{DS} = 0$ )	$I_{GSS}$	—	—	1.0	$\mu\text{Adc}$

**ON CHARACTERISTICS**

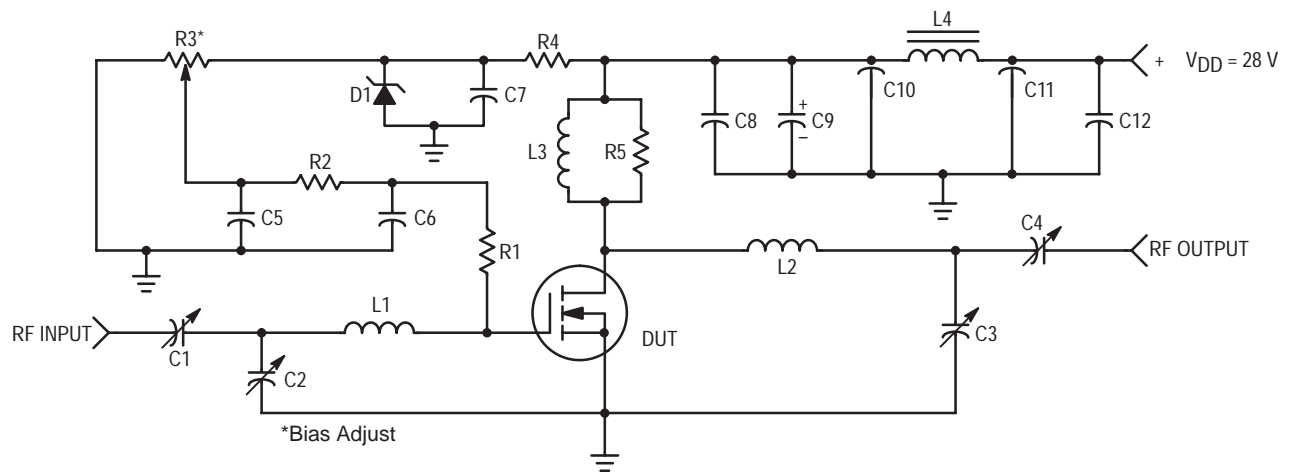

Gate Threshold Voltage ( $I_D = 10 \text{ mA}, V_{DS} = 10 \text{ V}$ )	$V_{GS(th)}$	1.0	3.5	6.0	Vdc
Forward Transconductance ( $V_{DS} = 10 \text{ V}, I_D = 100 \text{ mA}$ )	$g_{fs}$	80	110	—	mmhos

**DYNAMIC CHARACTERISTICS**

Input Capacitance ( $V_{DS} = 28 \text{ V}, V_{GS} = 0, f = 1.0 \text{ MHz}$ )	$C_{iss}$	—	7.0	—	pF

## DESIGN CONSIDERATIONS

The MRF134 is a RF power N-Channel enhancement mode field-effect transistor (FET) designed especially for VHF power amplifier and oscillator applications. Motorola RF MOS FETs feature a vertical structure with a planar design, thus avoiding the processing difficulties associated with V-groove vertical power FETs.

Motorola Application Note AN-211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

The major advantages of RF power FETs include high gain, low noise, simple bias systems, relative immunity from thermal runaway, and the ability to withstand severely mismatched loads without suffering damage. Power output can be varied over a wide range with a low power dc control signal, thus facilitating manual gain control, ALC and modulation.

## DC BIAS

The MRF134 is an enhancement mode FET and, therefore, does not conduct when drain voltage is applied. Drain current flows when a positive voltage is applied to the gate. See Figure 9 for a typical plot of drain current versus gate voltage. RF power FETs require forward bias for optimum performance. The value of quiescent drain current ( $I_{DQ}$ ) is not critical for many applications. The MRF134 was characterized at  $I_{DQ} = 50$  mA, which is the suggested minimum value of  $I_{DQ}$ . For special applications such as linear amplification,  $I_{DQ}$  may have to be selected to optimize the critical parameters.

The gate is a dc open circuit and draws no current. Therefore, the gate bias circuit may generally be just a simple resistive divider network. Some special applications may require a more elaborate bias system.

## GAIN CONTROL

Power output of the MRF134 may be controlled from its rated value down to zero (negative gain) by varying the dc gate voltage. This feature facilitates the design of manual gain control, AGC/ALC and modulation systems. (See Figure 8.)

## AMPLIFIER DESIGN

Impedance matching networks similar to those used with bipolar VHF transistors are suitable for MRF134. See Motorola Application Note AN721, Impedance Matching Networks Applied to RF Power Transistors. The higher input impedance of RF MOS FETs helps ease the task of broadband network design. Both small signal scattering parameters and large signal impedances are provided. While the s-parameters will not produce an exact design solution for high power operation, they do yield a good first approximation. This is an additional advantage of RF MOS power FETs.

RF power FETs are triode devices and, therefore, not unilateral. This, coupled with the very high gain of the MRF134, yields a device capable of self oscillation. Stability may be achieved by techniques such as drain loading, input shunt resistive loading, or output to input feedback. The MRF134 was characterized with a 68-ohm input shunt loading resistor. Two port parameter stability analysis with the MRF134 s-parameters provides a useful-tool for selection of loading or feedback circuitry to assure stable operation. See Motorola Application Note AN215A for a discussion of two port network theory and stability.

Input resistive loading is not feasible in low noise applications. The MRF134 noise figure data was generated in a circuit with drain loading and a low loss input network.

The RF MOSFET Line  
**RF Power**  
**Field-Effect Transistors**  
**N-Channel Enhancement-Mode MOSFET**

Designed for wideband large-signal amplifier and oscillator applications up to 400 MHz range, in single ended configuration.

- Guaranteed 28 Volt, 150 MHz Performance  
Output Power = 15 Watts  
Narrowband Gain = 16 dB (Typ)  
Efficiency = 60% (Typical)
- Small-Signal and Large-Signal Characterization
- 100% Tested For Load Mismatch At All Phase Angles With 30:1 VSWR
- Excellent Thermal Stability, Ideally Suited For Class A Operation
- Facilitates Manual Gain Control, ALC and Modulation Techniques

## DESIGN CONSIDERATIONS

The MRF136 is an RF power N-Channel enhancement mode field-effect transistor (FET) designed especially for HF and VHF power amplifier applications. Motorola RF MOS FETs feature planar design for optimum manufacturability.

Motorola Application Note AN211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

The major advantages of RF power FETs include high gain, low noise, simple bias systems, relative immunity from thermal runaway, and the ability to withstand severely mismatched loads without suffering damage. Power output can be varied over a wide range with a low power dc control signal, thus facilitating manual gain control, ALC and modulation.

## DC BIAS

The MRF136 is an enhancement mode FET and, therefore, does not conduct when drain voltage is applied without gate bias. A positive gate voltage causes drain current to flow (see Figure 10). RF power FETs require forward bias for optimum gain and power output. A Class AB condition with quiescent drain current ( $I_{DQ}$ ) in the 25–100 mA range is sufficient for many applications. For special requirements such as linear amplification,  $I_{DQ}$  may have to be adjusted to optimize the critical parameters.

The MOS gate is a dc open circuit. Since the gate bias circuit does not have to deliver any current to the FET, a simple resistive divider arrangement may sometimes suffice for this function. Special applications may require more elaborate gate bias systems.

## GAIN CONTROL

Power output of the MRF136 may be controlled from rated values down to the milliwatt region (>20 dB reduction in power output with constant input power) by varying the dc gate

voltage. This feature, not available in bipolar RF power devices, facilitates the incorporation of manual gain control, AGC/ALC and modulation schemes into system designs. A full range of power output control may require dc gate voltage excursions into the negative region.

## AMPLIFIER DESIGN

Impedance matching networks similar to those used with bipolar transistors are suitable for MRF136. See Motorola Application Note AN721, Impedance Matching Networks Applied to RF Power Transistors. Both small signal scattering parameters and large signal impedance parameters are provided. Large signal impedances should be used for network designs wherever possible. While the s parameters will not produce an exact design solution for high power operation, they do yield a good first approximation. This is particularly useful at frequencies outside those presented in the large signal impedance plots.

RF power FETs are triode devices and are therefore not unilateral. This, coupled with the very high gain, yields a device capable of self oscillation. Stability may be achieved using techniques such as drain loading, input shunt resistive loading, or feedback. S parameter stability analysis can provide useful information in the selection of loading and/or feedback to insure stable operation. The MRF136 was characterized with a 27 ohm input shunt loading resistor.

For further discussion of RF amplifier stability and the use of two port parameters in RF amplifier design, see Motorola Application Note AN215A.

## LOW NOISE OPERATION

Input resistive loading will degrade noise performance, and noise figure may vary significantly with gate driving impedance. A low loss input matching network with its gate impedance optimized for lowest noise is recommended.

The RF MOSFET Line  
**RF Power Field-Effect Transistor**  
N-Channel Enhancement-Mode MOSFET

Designed for broadband commercial and military applications at frequencies to 175 MHz. The high power, high gain and broadband performance of this device makes possible solid state transmitters for FM broadcast or TV channel frequency bands.

- Guaranteed Performance at 30 MHz, 28 V:  
Output Power — 150 W  
Gain — 18 dB (22 dB Typ)  
Efficiency — 40%
- Typical Performance at 175 MHz, 50 V:  
Output Power — 150 W  
Gain — 13 dB
- Low Thermal Resistance
- Ruggedness Tested at Rated Output Power
- Nitride Passivated Die for Enhanced Reliability
- S-Parameters Available for Download into Frequency Domain Simulators.  
See <http://motorola.com/sps/rf/designtds/>

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal anode gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the MOSFET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iss}$ ), output ( $C_{oss}$ ) and reverse transfer ( $C_{rss}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iss}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### LINEARITY AND GAIN CHARACTERISTICS

In addition to the typical IMD and power gain data presented, Figure 4 may give the designer additional information on the capabilities of this device. The graph represents the small signal unity current gain frequency at a given drain current level. This is equivalent to  $f_T$  for bipolar transistors.

Since this test is performed at a fast sweep speed, heating of the device does not occur. Thus, in normal use, the higher temperatures may degrade these characteristics to some extent.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gate of this device is essentially a capacitor. Circuits that leave the gate open-circuited or floating should be avoided. These conditions can result in turn-on of the device due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — This device does not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

Using a resistor to keep the gate-to-source impedance low also helps damp transients and serves another important function. Voltage transients on the drain can be coupled to the gate through the parasitic gate-drain capacitance. If the gate-to-source impedance and the rate of voltage change on the drain are both high, then the signal coupled to the gate may be large enough to exceed the gate-threshold voltage and turn the device on.

#### **HANDLING CONSIDERATIONS**

When shipping, the devices should be transported only in antistatic bags or conductive foam. Upon removal from the packaging, careful handling procedures should be adhered to. Those handling the devices should wear grounding straps and devices not in the antistatic packaging should be kept in metal tote bins. MOSFETs should be handled by the case and not by the leads, and when testing the device, all leads should make good electrical contact before voltage is applied. As a final note, when placing the FET into the system it is designed for, soldering should be done with a grounded iron.

#### **DESIGN CONSIDERATIONS**

The MRF141 is an RF Power, MOS, N-channel enhancement mode field-effect transistor (FET) designed for HF and VHF power amplifier applications.

Motorola Application Note AN211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

The major advantages of RF power MOSFETs include high gain, low noise, simple bias systems, relative immunity from thermal runaway, and the ability to withstand severely mismatched loads without suffering damage. Power output can be varied over a wide range with a low power dc control signal.

#### **DC BIAS**

The MRF141 is an enhancement mode FET and, therefore, does not conduct when drain voltage is applied. Drain current flows when a positive voltage is applied to the gate. RF power FETs require forward bias for optimum performance. The value of quiescent drain current ( $I_{DQ}$ ) is not critical for many applications. The MRF141 was characterized at  $I_{DQ} = 250$  mA, each side, which is the suggested minimum value of  $I_{DQ}$ . For special applications such as linear amplification,  $I_{DQ}$  may have to be selected to optimize the critical parameters.

The gate is a dc open circuit and draws no current. Therefore, the gate bias circuit may be just a simple resistive divider network. Some applications may require a more elaborate bias system.

#### **GAIN CONTROL**

Power output of the MRF141 may be controlled from its rated value down to zero (negative gain) by varying the dc gate voltage. This feature facilitates the design of manual gain control, AGC/ALC and modulation systems.

The RF MOSFET Line  
**RF Power Field-Effect Transistor**  
N-Channel Enhancement-Mode MOSFET

Designed for broadband commercial and military applications at frequencies to 175 MHz. The high power, high gain and broadband performance of this device makes possible solid state transmitters for FM broadcast or TV channel frequency bands.

- Guaranteed Performance at 175 MHz, 28 V:  
Output Power — 300 W  
Gain — 12 dB (14 dB Typ)  
Efficiency — 50%
- Low Thermal Resistance — 0.35°C/W
- Ruggedness Tested at Rated Output Power
- Nitride Passivated Die for Enhanced Reliability
- S-Parameters Available for Download into Frequency Domain Simulators.  
See <http://motorola.com/sps/rf/designtds/>

Reverse Transfer Capacitance ( $V_{DS} = 28\text{ V}, V_{GS} = 0, f = 1.0\text{ MHz}$ )	$C_{rss}$	—	35	—	pF

**FUNCTIONAL TESTS (2)**

Common Source Amplifier Power Gain ( $V_{DD} = 28\text{ V}, P_{out} = 300\text{ W}, I_{DQ} = 500\text{ mA}, f = 175\text{ MHz}$ )	$G_{ps}$	12	14	—	dB
Drain Efficiency ( $V_{DD} = 28\text{ V}, P_{out} = 300\text{ W}, f = 175\text{ MHz}, I_D(\text{Max}) = 21.4\text{ A}$ )	$\eta$	45	55	—	%
Load Mismatch ( $V_{DD} = 28\text{ V}, P_{out} = 300\text{ W}, I_{DQ} = 500\text{ mA}, f = 175\text{ MHz},$ $V_{SWR} 5:1$ at all Phase Angles)	$\psi$	No Degradation in Output Power			

## NOTES:

- Each side measured separately.
- Measured in push–pull configuration.

- C1 — Arco 402, 1.5–20 pF
- C2 — Arco 406, 15–115 pF
- C3, C4, C8, C9, C10 — 1000 pF Chip
- C5, C11 — 0.1  $\mu$ F Chip
- C6 — 330 pF Chip
- C7 — 200 pF and 180 pF Chips in Parallel
- C12 — 0.47  $\mu$ F Ceramic Chip, Kemet 1215 or Equivalent
- C13 — Arco 403, 3.0–35 pF
- L1 — 10 Turns AWG #16 Enameled Wire, Close Wound, 1/4" I.D.
- L2 — Ferrite Beads of Suitable Material for 1.5–2.0  $\mu$ H Total Inductance
- R1 — 100 Ohms, 1/2 W
- R2 — 1.0 kOhm, 1/2 W

- T1 — 9:1 RF Transformer. Can be made of 15–18 Ohms Semirigid Co-Ax, 62–90 Mils O.D.
- T2 — 1:9 RF Transformer. Can be made of 15–18 Ohms Semirigid Co-Ax, 70–90 Mils O.D.
- Board Material — 0.062" Fiberglass (G10), 1 oz. Copper Clad, 2 Sides,  $\epsilon_r = 5$
- NOTE: For stability, the input transformer T1 must be loaded with ferrite toroids or beads to increase the common mode inductance. For operation below 100 MHz. The same is required for the output transformer.
- See pictures for construction details.

Unless Otherwise Noted, All Chip Capacitors are ATC Type 100 or Equivalent.

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal anode gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the MOSFET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iSS}$ ), output ( $C_{oSS}$ ) and reverse transfer ( $C_{rSS}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iSS}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### LINEARITY AND GAIN CHARACTERISTICS

In addition to the typical IMD and power gain data presented, Figure 4 may give the designer additional information on the capabilities of this device. The graph represents the small signal unity current gain frequency at a given drain current level. This is equivalent to  $f_T$  for bipolar transistors. Since this test is performed at a fast sweep speed, heating of the device does not occur. Thus, in normal use, the higher temperatures may degrade these characteristics to some extent.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gate of this device is essentially a capacitor. Circuits that leave the gate open-circuited or float-

ing should be avoided. These conditions can result in turn-on of the device due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — This device does not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

Using a resistor to keep the gate-to-source impedance low also helps damp transients and serves another important function. Voltage transients on the drain can be coupled to the gate through the parasitic gate-drain capacitance. If the gate-to-source impedance and the rate of voltage change on the drain are both high, then the signal coupled to the gate may be large enough to exceed the gate-threshold voltage and turn the device on.

### HANDLING CONSIDERATIONS

When shipping, the devices should be transported only in antistatic bags or conductive foam. Upon removal from the packaging, careful handling procedures should be adhered to. Those handling the devices should wear grounding straps and devices not in the antistatic packaging should be kept in metal tote bins. MOSFETs should be handled by the case and not by the leads, and when testing the device, all leads should make good electrical contact before voltage is applied. As a final note, when placing the FET into the system it is designed for, soldering should be done with a grounded iron.

### DESIGN CONSIDERATIONS

The MRF141G is an RF Power, MOS, N-channel enhancement mode field-effect transistor (FET) designed for HF and VHF power amplifier applications.

Motorola Application Note AN211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

The major advantages of RF power MOSFETs include high gain, low noise, simple bias systems, relative immunity from thermal runaway, and the ability to withstand severely mismatched loads without suffering damage. Power output can be varied over a wide range with a low power dc control signal.

### DC BIAS

The MRF141G is an enhancement mode FET and, therefore, does not conduct when drain voltage is applied. Drain current flows when a positive voltage is applied to the gate. RF power FETs require forward bias for optimum performance. The value of quiescent drain current ( $I_{DQ}$ ) is not critical for many applications. The MRF141G was characterized at  $I_{DQ} = 250$  mA, each side, which is the suggested minimum value of  $I_{DQ}$ . For special applications such as linear amplification,  $I_{DQ}$  may have to be selected to optimize the critical parameters.

The gate is a dc open circuit and draws no current. Therefore, the gate bias circuit may be just a simple resistive divider network. Some applications may require a more elaborate bias system.

### GAIN CONTROL

Power output of the MRF141G may be controlled from its rated value down to zero (negative gain) by varying the dc gate voltage. This feature facilitates the design of manual gain control, AGC/ALC and modulation systems.

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal oxide gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the RF MOSFET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iss}$ ), output ( $C_{oss}$ ) and reverse transfer ( $C_{rss}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iss}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### LINEARITY AND GAIN CHARACTERISTICS

In addition to the typical IMD and power gain data presented, Figure 5 may give the designer additional information on the capabilities of this device. The graph represents the small signal unity current gain frequency at a given drain current level. This is equivalent to  $f_T$  for bipolar transistors.

Since this test is performed at a fast sweep speed, heating of the device does not occur. Thus, in normal use, the higher temperatures may degrade these characteristics to some extent.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the RF MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gates of these devices are essentially capacitors. Circuits that leave the gate open-circuited or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — These devices do not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal oxide gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the RF MOSFET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iss}$ ), output ( $C_{oss}$ ) and reverse transfer ( $C_{rss}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iss}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### LINEARITY AND GAIN CHARACTERISTICS

In addition to the typical IMD and power gain data presented, Figure 5 may give the designer additional information on the capabilities of this device. The graph represents the small signal unity current gain frequency at a given drain current level. This is equivalent to  $f_T$  for bipolar transistors.

Since this test is performed at a fast sweep speed, heating of the device does not occur. Thus, in normal use, the higher temperatures may degrade these characteristics to some extent.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the RF MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gates of these devices are essentially capacitors. Circuits that leave the gate open-circuited or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — These devices do not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

## EQUIVALENT TRANSISTOR PARAMETER TERMINOLOGY

Collector .....	Drain

### N-Channel Enhancement-Mode MOSFET

Designed for broadband commercial and military applications at frequencies to 175 MHz. The high power, high gain and broadband performance of this device makes possible solid state transmitters for FM broadcast or TV channel frequency bands.

- Guaranteed Performance at 30 MHz, 50 V:  
Output Power — 150 W  
Gain — 18 dB (22 dB Typ)  
Efficiency — 40%
- Typical Performance at 175 MHz, 50 V:  
Output Power — 150 W  
Gain — 13 dB
- Low Thermal Resistance
- Ruggedness Tested at Rated Output Power
- Nitride Passivated Die for Enhanced Reliability
- S-Parameters Available for Download into Frequency Domain Simulators. See <http://motorola.com/sps/rf/designrtds/>

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal anode gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the MOSFET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iSS}$ ), output ( $C_{oSS}$ ) and reverse transfer ( $C_{rSS}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iSS}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### LINEARITY AND GAIN CHARACTERISTICS

In addition to the typical IMD and power gain data presented, Figure 6 may give the designer additional information on the capabilities of this device. The graph represents the small signal unity current gain frequency at a given drain current level. This is equivalent to  $f_T$  for bipolar transistors. Since this test is performed at a fast sweep speed, heating of the device does not occur. Thus, in normal use, the higher temperatures may degrade these characteristics to some extent.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gate of this device is essentially a capacitor. Circuits that leave the gate open-circuited or float-

ing should be avoided. These conditions can result in turn-on of the device due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — This device does not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

Using a resistor to keep the gate-to-source impedance low also helps damp transients and serves another important function. Voltage transients on the drain can be coupled to the gate through the parasitic gate-drain capacitance. If the gate-to-source impedance and the rate of voltage change on the drain are both high, then the signal coupled to the gate may be large enough to exceed the gate-threshold voltage and turn the device on.

### HANDLING CONSIDERATIONS

When shipping, the devices should be transported only in antistatic bags or conductive foam. Upon removal from the packaging, careful handling procedures should be adhered to. Those handling the devices should wear grounding straps and devices not in the antistatic packaging should be kept in metal tote bins. MOSFETs should be handled by the case and not by the leads, and when testing the device, all leads should make good electrical contact before voltage is applied. As a final note, when placing the FET into the system it is designed for, soldering should be done with a grounded iron.

### DESIGN CONSIDERATIONS

The MRF151 is an RF Power, MOS, N-channel enhancement mode field-effect transistor (FET) designed for HF and VHF power amplifier applications.

Motorola Application Note AN211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

The major advantages of RF power MOSFETs include high gain, low noise, simple bias systems, relative immunity from thermal runaway, and the ability to withstand severely mismatched loads without suffering damage. Power output can be varied over a wide range with a low power dc control signal.

### DC BIAS

The MRF151 is an enhancement mode FET and, therefore, does not conduct when drain voltage is applied. Drain current flows when a positive voltage is applied to the gate. RF power FETs require forward bias for optimum performance. The value of quiescent drain current ( $I_{DQ}$ ) is not critical for many applications. The MRF151 was characterized at  $I_{DQ} = 250$  mA, each side, which is the suggested minimum value of  $I_{DQ}$ . For special applications such as linear amplification,  $I_{DQ}$  may have to be selected to optimize the critical parameters.

The gate is a dc open circuit and draws no current. Therefore, the gate bias circuit may be just a simple resistive divider network. Some applications may require a more elaborate bias system.

### GAIN CONTROL

Power output of the MRF151 may be controlled from its rated value down to zero (negative gain) by varying the dc gate voltage. This feature facilitates the design of manual gain control, AGC/ALC and modulation systems.

The RF MOSFET Line  
**RF Power Field-Effect Transistor**  
N-Channel Enhancement-Mode MOSFET

Designed for broadband commercial and military applications at frequencies to 175 MHz. The high power, high gain and broadband performance of this device makes possible solid state transmitters for FM broadcast or TV channel frequency bands.

- Guaranteed Performance at 175 MHz, 50 V:  
Output Power — 300 W  
Gain — 14 dB (16 dB Typ)  
Efficiency — 50%
- Low Thermal Resistance — 0.35°C/W
- Ruggedness Tested at Rated Output Power
- Nitride Passivated Die for Enhanced Reliability
- S-Parameters Available for Download into Frequency Domain Simulators.

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal anode gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the RF MOSFET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iss}$ ), output ( $C_{oss}$ ) and reverse transfer ( $C_{rss}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iss}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### LINEARITY AND GAIN CHARACTERISTICS

In addition to the typical IMD and power gain data presented, Figure 3 may give the designer additional gain information on the capabilities of this device. The graph represents the small signal unity current gain frequency at a given drain current level. This is equivalent to  $f_T$  for bipolar transistors. Since this test is performed at a fast sweep speed, heating of the device does not occur. Thus, in normal use, the higher temperatures may degrade these characteristics to some extent.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gates of these devices are essentially capacitors. Circuits that leave the gate open-cir-

cuted or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — These devices do not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

Using a resistor to keep the gate-to-source impedance low also helps damp transients and serves another important function. Voltage transients on the drain can be coupled to the gate through the parasitic gate-drain capacitance. If the gate-to-source impedance and the rate of voltage change on the drain are both high, then the signal coupled to the gate may be large enough to exceed the gate-threshold voltage and turn the device on.

### HANDLING CONSIDERATIONS

When shipping, the devices should be transported only in antistatic bags or conductive foam. Upon removal from the packaging, careful handling procedures should be adhered to. Those handling the devices should wear grounding straps and devices not in the antistatic packaging should be kept in metal tote bins. MOSFETs should be handled by the case and not by the leads, and when testing the device, all leads should make good electrical contact before voltage is applied. As a final note, when placing the FET into the system it is designed for, soldering should be done with a grounded iron.

### DESIGN CONSIDERATIONS

The MRF151G is an RF Power, MOS, N-channel enhancement mode field-effect transistor (FET) designed for HF and VHF power amplifier applications.

Motorola Application Note AN211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

The major advantages of RF power MOSFETs include high gain, low noise, simple bias systems, relative immunity from thermal runaway, and the ability to withstand severely mismatched loads without suffering damage. Power output can be varied over a wide range with a low power dc control signal.

### DC BIAS

The MRF151G is an enhancement mode FET and, therefore, does not conduct when drain voltage is applied. Drain current flows when a positive voltage is applied to the gate. RF power FETs require forward bias for optimum performance. The value of quiescent drain current ( $I_{DQ}$ ) is not critical for many applications. The MRF151G was characterized at  $I_{DQ} = 250$  mA, each side, which is the suggested minimum value of  $I_{DQ}$ . For special applications such as linear amplification,  $I_{DQ}$  may have to be selected to optimize the critical parameters.

The gate is a dc open circuit and draws no current. Therefore, the gate bias circuit may be just a simple resistive divider network. Some applications may require a more elaborate bias system.

### GAIN CONTROL

Power output of the MRF151G may be controlled from its rated value down to zero (negative gain) by varying the dc gate voltage. This feature facilitates the design of manual gain control, AGC/ALC and modulation systems.

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal oxide gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the RF MOSFET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iss}$ ), output ( $C_{oss}$ ) and reverse transfer ( $C_{rss}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iss}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### LINEARITY AND GAIN CHARACTERISTICS

In addition to the typical IMD and power gain data presented, Figure 5 may give the designer additional information on the capabilities of this device. The graph represents the small signal unity current gain frequency at a given drain current level. This is equivalent to  $f_T$  for bipolar transistors. Since this test is performed at a fast sweep speed, heating of the device does not occur. Thus, in normal use, the higher temperatures may degrade these characteristics to some extent.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the RF MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gates of these devices are essentially capacitors. Circuits that leave the gate open-circuited or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — These devices do not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

### MOUNTING OF HIGH POWER RF POWER TRANSISTORS

The package of this device is designed for conduction cooling. It is extremely important to minimize the thermal resistance between the device flange and the heat dissipator.

Since the device mounting flange is made of soft copper, it may be deformed during various stages of handling or during transportation. It is recommended that the user makes a final inspection on this before the device installation.  $\pm 0.0005$ " is considered sufficient for the flange bottom.

The same applies to the heat dissipator in the device mounting area. If copper heatsink is not used, a copper head spreader is strongly recommended between the device mounting surfaces and the main heatsink. It should be at least 1/4" thick and extend at least one inch from the flange edges. A thin layer of thermal compound in all interfaces is, of course, essential. The recommended torque on the 4–40 mounting screws should be in the area of 4–5 lbs.-inch, and spring type lock washers along with flat washers are recommended.

For die temperature calculations, the  $\Delta$  temperature from a corner mounting screw area to the bottom center of the flange is approximately  $5^\circ\text{C}$  and  $10^\circ\text{C}$  under normal operating conditions (dissipation 150 W and 300 W respectively).

The main heat dissipator must be sufficiently large and have low  $R_\theta$  for moderate air velocity, unless liquid cooling is employed.

**CIRCUIT CONSIDERATIONS**

At high power levels (500 W and up), the circuit layout becomes critical due to the low impedance levels and high RF currents associated with the output matching. Some of the components, such as capacitors and inductors must also withstand these currents. The component losses are directly proportional to the operating frequency. The manufacturers

specifications on capacitor ratings should be consulted on these aspects prior to design.

Push-pull circuits are less critical in general, since the ground referenced RF loops are practically eliminated, and the impedance levels are higher for a given power output. High power broadband transformers are also easier to design than comparable LC matching networks.

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal oxide gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the TMOS<sup>®</sup> FET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iSS}$ ), output ( $C_{oSS}$ ) and reverse transfer ( $C_{rSS}$ ) capacitances on data sheets. The relationships between the interterminal capacitances and those given on data sheets are shown below. The  $C_{iSS}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### LINEARITY AND GAIN CHARACTERISTICS

In addition to the typical IMD and power gain data presented, Figure 5 may give the designer additional information on the capabilities of this device. The graph represents the small signal unity current gain frequency at a given drain current level. This is equivalent to  $f_T$  for bipolar transistors. Since this test is performed at a fast sweep speed, heating of the device does not occur. Thus, in normal use, the higher temperatures may degrade these characteristics to some extent.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the TMOS FET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gates of these devices are essentially capacitors. Circuits that leave the gate open-circuited or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — These devices do not have an internal monolithic zener diode from gate-to-source. The addition of an internal zener diode may result in detrimental effects on the reliability of a power MOSFET. If gate protection is required, an external zener diode is recommended.

### IMPEDANCE CHARACTERISTICS

Device input and output impedances are normally obtained by measuring their conjugates in an optimized narrow band test circuit. These test circuits are designed and constructed for a number of frequency points depending on the frequency coverage of characterization. For low frequencies the circuits consist of standard LC matching networks including variable capacitors for peak tuning. At increasing power levels the output impedance decreases, resulting in higher RF currents in the matching network. This makes the practicality of output impedance measurements in the manner described questionable at power levels higher than 200–300 W for devices operated at 50 V and 150–200 W for devices operated at 28 V. The physical sizes and values required for the components to withstand the RF currents increase to a point where physical construction of the output matching network gets difficult if not impossible. For this reason the output impedances are not given for high power devices such as the MRF154 and MRF157. However, formulas like  $\frac{(V_{DS} - V_{sat})^2}{2P_{out}}$  for a single ended design or  $\frac{2((V_{DS} - V_{sat})^2)}{P_{out}}$  for a push-pull design can be used to obtain reasonably close approximations to actual values.

### MOUNTING OF HIGH POWER RF POWER TRANSISTORS

The package of this device is designed for conduction cooling. It is extremely important to minimize the thermal resistance between the device flange and the heat dissipator.

If a copper heatsink is not used, a copper head spreader is strongly recommended between the device mounting surfaces and the main heatsink. It should be at least 1/4" thick and extend at least one inch from the flange edges. A thin layer of thermal compound in all interfaces is, of course, essential. The recommended torque on the 4–40 mounting screws should be in the area of 4–5 lbs.-inch, and spring type lock washers along with flat washers are recommended.

For die temperature calculations, the  $\Delta$  temperature from a corner mounting screw area to the bottom center of the flange is approximately 5°C and 10°C under normal operating conditions (dissipation 150 W and 300 W respectively).

The main heat dissipator must be sufficiently large and have low  $R_{\theta}$  for moderate air velocity, unless liquid cooling is employed.

### CIRCUIT CONSIDERATIONS

At high power levels (500 W and up), the circuit layout becomes critical due to the low impedance levels and high RF currents associated with the output matching. Some of the components, such as capacitors and inductors must also withstand these currents. The component losses are directly proportional to the operating frequency. The manufacturers specifications on capacitor ratings should be consulted on these aspects prior to design.

Push-pull circuits are less critical in general, since the ground referenced RF loops are practically eliminated, and the impedance levels are higher for a given power output. High power broadband transformers are also easier to design than comparable LC matching networks.

The RF TMOS® Line  
**Power Field Effect Transistor**  
N-Channel Enhancement Mode

Designed for wideband large-signal amplifier and oscillator applications to 500 MHz.

- Guaranteed 28 Volt, 400 MHz Performance  
Output Power = 2.0 Watts  
Minimum Gain = 16 dB  
Efficiency = 55% (Typical)
- Grounded Source Package for High Gain and Excellent Heat Dissipation (MRF158R)
- Facilitates Manual Gain Control, ALC and Modulation Techniques
- 100% Tested for Load Mismatch at All Phase Angles with 30:1 VSWR
- Excellent Thermal Stability, Ideally Suited for Class A Operation
- Circuit board photomaster available upon request by contacting RF Tactical Marketing in Phoenix, AZ.
- S-Parameters Available for Download into Frequency Domain Simulators. See <http://motorola.com/sps/rf/designrtds/>

The RF MOSFET Line  
**Power Field-Effect Transistor**  
N-Channel Enhancement-Mode

Designed primarily for wideband large-signal output and driver stages from 100 – 500 MHz.

- Guaranteed Performance @ 500 MHz, 28 Vdc  
Output Power — 150 Watts  
Power Gain — 10 dB (Min)  
Efficiency — 50% (Min)  
100% Tested for Load Mismatch at all Phase Angles with VSWR 30:1
- Overall Lower Capacitance @ 28 V  
C<sub>iss</sub> — 135 pF  
C<sub>oss</sub> — 140 pF  
C<sub>rss</sub> — 17 pF
- Simplified AVC, ALC and Modulation

Typical data for power amplifiers in industrial and commercial applications:

- Typical Performance @ 400 MHz, 28 Vdc  
Output Power — 150 Watts  
Power Gain — 12.5 dB  
Efficiency — 60%
- Typical Performance @ 225 MHz, 28 Vdc  
Output Power — 200 Watts  
Power Gain — 15 dB  
Efficiency — 65%
- S-Parameters Available for Download into Frequency Domain Simulators.

**MAXIMUM RATINGS**

Rating	Symbol	Value	Unit
Drain-Source Voltage	V <sub>DSS</sub>	65	Vdc
Drain-Gate Voltage (R <sub>GS</sub> = 1.0 MΩ)	V <sub>DGR</sub>	65	Vdc
Gate-Source Voltage	V <sub>GS</sub>	±40	Adc
Drain Current — Continuous	I <sub>D</sub>	26	Adc
Total Device Dissipation @ T <sub>C</sub> = 25°C Derate above 25°C	P <sub>D</sub>	400 2.27	Watts W/°C
Storage Temperature Range	T <sub>stg</sub>	-65 to +150	°C
Operating Junction Temperature	T <sub>J</sub>	200	°C

**THERMAL CHARACTERISTICS**

Characteristic	Symbol	Max	Unit
Thermal Resistance, Junction to Case	R <sub>θJC</sub>	0.44	°C/W

NOTE – **CAUTION** – MOS devices are susceptible to damage from electrostatic charge. Reasonable precautions in handling and packaging MOS devices should be observed.

**ELECTRICAL CHARACTERISTICS** ( $T_C = 25^\circ\text{C}$  unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
----------------	--------	-----	-----	-----	------

**OFF CHARACTERISTICS (1)**

Drain–Source Breakdown Voltage ( $V_{GS} = 0, I_D = 50 \text{ mA}$ )	$V_{(BR)DSS}$	65	—	—	Vdc
Zero Gate Voltage Drain Current ( $V_{DS} = 28 \text{ V}, V_{GS} = 0$ )	$I_{DSS}$	—	—	1	mA
Gate–Source Leakage Current ( $V_{GS} = 20 \text{ V}, V_{DS} = 0$ )	$I_{GSS}$	—	—	1	$\mu\text{A}$

**ON CHARACTERISTICS (1)**

Gate Threshold Voltage ( $V_{DS} = 10 \text{ V}, I_D = 100 \text{ mA}$ )	$V_{GS(th)}$	1.5	2.5	4.5	Vdc
Drain–Source On–Voltage ( $V_{GS} = 10 \text{ V}, I_D = 5 \text{ A}$ )	$V_{DS(on)}$	0.5	0.9	1.5	Vdc
Forward Transconductance ( $V_{DS} = 10 \text{ V}, I_D = 2.5 \text{ A}$ )	$g_{fs}$	3	3.75	—	mhos

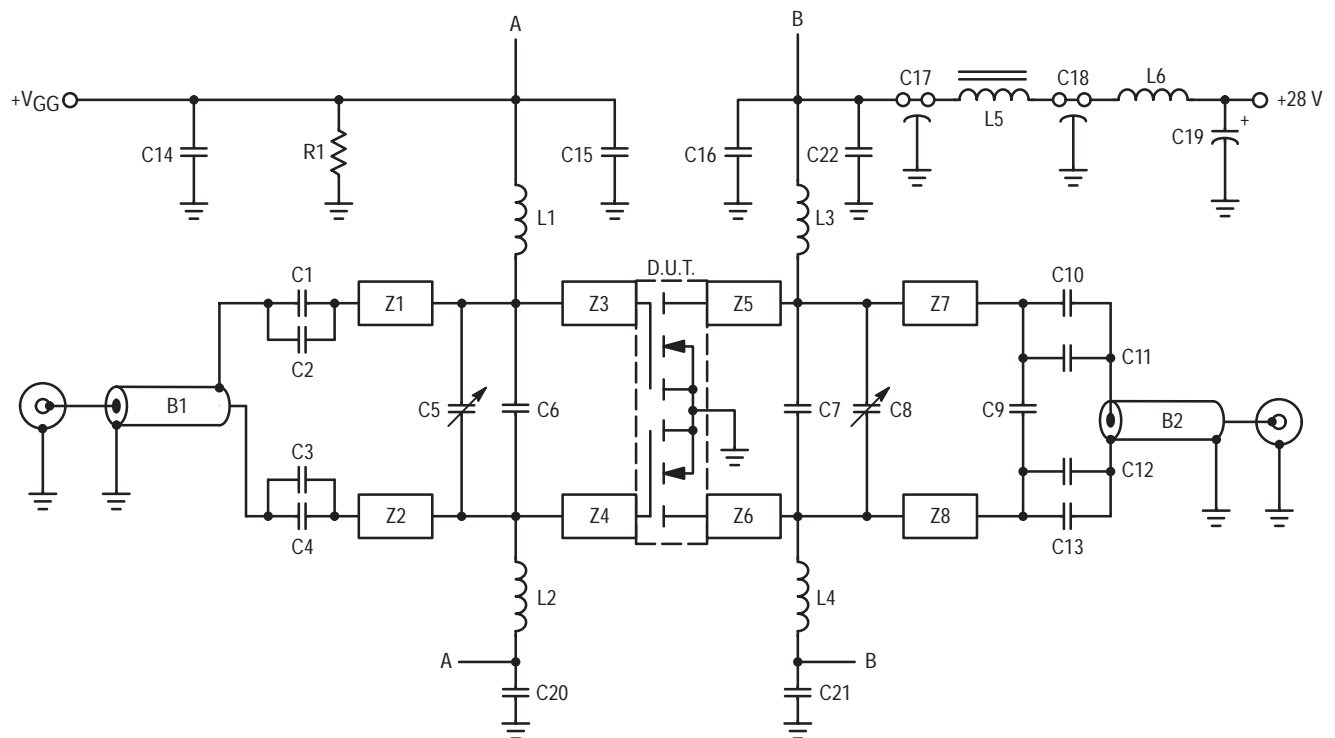

**DYNAMIC CHARACTERISTICS (1)**

Input Capacitance ( $V_{DS} = 28 \text{ V}, V_{GS} = 0, f = 1 \text{ MHz}$ )	$C_{iss}$	—	135	—	pF
Output Capacitance ( $V_{DS} = 28 \text{ V}, V_{GS} = 0, f = 1 \text{ MHz}$ )	$C_{oss}$	—	140	—	pF
Reverse Transfer Capacitance ( $V_{DS} = 28 \text{ V}, V_{GS} = 0, f = 1 \text{ MHz}$ )	$C_{rss}$	—	17	—	pF

**FUNCTIONAL CHARACTERISTICS (2)** (Figure 1)

Common Source Power Gain ( $V_{DD} = 28 \text{ V}, P_{out} = 150 \text{ W}, f = 500 \text{ MHz}, I_{DQ} = 2 \times 100 \text{ mA}$ )	$G_{ps}$	10	11.2	—	dB
Drain Efficiency ( $V_{DD} = 28 \text{ V}, P_{out} = 150 \text{ W}, f = 500 \text{ MHz}, I_{DQ} = 2 \times 100 \text{ mA}$ )	$\eta$	50	55	—	%
Electrical Ruggedness ( $V_{DD} = 28 \text{ V}, P_{out} = 150 \text{ W}, f = 500 \text{ MHz}, I_{DQ} = 2 \times 100 \text{ mA},$ VSWR 30:1 at all Phase Angles)	$\psi$	No Degradation in Output Power			

1. Each side of device measured separately.
2. Measured in push–pull configuration.

## TYPICAL CHARACTERISTICS

**Figure 8. Capacitance versus Drain-Source Voltage\***  
 \*Data shown applies only to one half of device, MRF275G

**Figure 9. Gate-Source Voltage versus Case Temperature**

**Figure 10. DC Safe Operating Area**

$V_{DD} = 28\text{ V}$ ,  $I_{DQ} = 2 \times 100\text{ mA}$ ,  $P_{Out} = 150\text{ W}$

f (MHz)	$Z_{in}$ Ohms	$Z_{OL}^*$ Ohms
225	$1.6 - j2.30$	$3.2 - j1.50$
400	$1.9 + j0.48$	$2.3 - j0.19$
500	$1.9 + j2.60$	$2.0 + j1.30$

$Z_{OL}^*$  = Conjugate of the optimum load impedance into which the device operates at a given output power, voltage and frequency.

Note: Input and output impedance values given are measured from gate to gate and drain to drain respectively.

Figure 11. Series Equivalent Input/Output Impedance

B1	Balun, 50 $\Omega$ , 0.086" O.D. 2" Long, Semi Rigid Coax	L1, L2	#18 Wire, Hairpin Inductor
B2	Balun, 50 $\Omega$ , 0.141" O.D. 2" Long, Semi Rigid Coax	L3, L4	12 Turns #18, 0.340" I.D., Enameled Wire
C1, C2, C8, C9	270 pF, ATC Chip Capacitor	L5	Ferroxcube VK200 20/4B
C3, C5, C7	1.0–20 pF, Trimmer Capacitor	L6	3 Turns #16, 0.340" I.D., Enameled Wire
C4	15 pF, ATC Chip Capacitor	R1	1.0 k $\Omega$ , 1/4 W Resistor
C6	33 pF, ATC Chip Capacitor	R2, R3	10 k $\Omega$ , 1/4 W Resistor
C10, C12, C13, C16, C17	0.01 $\mu$ F, Ceramic Capacitor	Z1, Z2	0.400" x 0.250", Microstrip Line
C11	1.0 $\mu$ F, 50 V, Tantalum	Z3, Z4	0.870" x 0.250", Microstrip Line
C14, C15	680 pF, Feedthru Capacitor	Z5, Z6	0.500" x 0.250", Microstrip Line
C18	20 $\mu$ F, 50 V, Tantalum	Board material	0.060" Teflon–fiberglass, $\epsilon_r = 2.55$ , copper clad both sides, 2 oz. copper.

Figure 12. 400 MHz Test Circuit

C1	8.0–60 pF, Arco 404	R1	100 $\Omega$ , 1/2 W
C2, C3, C7, C8	1000 pF, Chip Capacitor	R2	1.0 k $\Omega$ , 1/2 W
C4, C9	0.1 $\mu$ F, Chip Capacitor	T1	4:1 Impedance Ratio, RF Transformer Can Be Made of 25 $\Omega$ , Semi Rigid Coax, 47–52 Mils O.D.
C5	180 pF, Chip Capacitor	T2	1:9 Impedance Ratio, RF Transformer. Can Be Made of 15–18 $\Omega$ , Semi Rigid Coax, 62–90 Mils O.D.
C6	100 pF and 130 pF, Chips in Parallel		
C10	0.47 $\mu$ F, Chip Capacitor, 1215 or Equivalent, Kemet		
L1	10 Turns AWG #16, 1/4" I.D., Enamel Wire, Close Wound		
L2	Ferrite Beads of Suitable Material for 1.5–2.0 $\mu$ H Total Inductance		

NOTE: For stability, the input transformer T1 should be loaded with ferrite toroids or beads to increase the common mode inductance. For operation below 100 MHz. The same is required for the output transformer.

Board material 062" fiberglass (G10),  
 $\epsilon_r \approx 5$ , Two sided, 1 oz. Copper.  
 Unless otherwise noted, all chip capacitors  
 are ATC Type 100 or Equivalent.

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal oxide gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the MOSFET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iSS}$ ), output ( $C_{oSS}$ ) and reverse transfer ( $C_{rSS}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iSS}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

The  $C_{iSS}$  given in the electrical characteristics table was measured using method 2 above. It should be noted that  $C_{iSS}$ ,  $C_{oSS}$ ,  $C_{rSS}$  are measured at zero drain current and are provided for general information about the device. They are not RF design parameters and no attempt should be made to use them as such.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating (or any of the maximum ratings on the front page). Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gates of this device are essentially capacitors. Circuits that leave the gate open-circuited or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — These devices do not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

Using a resistor to keep the gate-to-source impedance low also helps damp transients and serves another important function. Voltage transients on the drain can be coupled to the gate through the parasitic gate-drain capacitance. If the gate-to-source impedance and the rate of voltage change on the drain are both high, then the signal coupled to the gate

may be large enough to exceed the gate–threshold voltage and turn the device on.

### **HANDLING CONSIDERATIONS**

When shipping, the devices should be transported only in antistatic bags or conductive foam. Upon removal from the packaging, careful handling procedures should be adhered to. Those handling the devices should wear grounding straps and devices not in the antistatic packaging should be kept in metal tote bins. MOSFETs should be handled by the case and not by the leads, and when testing the device, all leads should make good electrical contact before voltage is applied. As a final note, when placing the FET into the system it is designed for, soldering should be done with grounded equipment.

### **DESIGN CONSIDERATIONS**

The MRF275G is a RF power N–channel enhancement mode field–effect transistor (FETs) designed for HF, VHF and UHF power amplifier applications. Motorola RF MOSFETs feature a vertical structure with a planar design.

Motorola Application Note AN211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

The major advantages of RF power FETs include high gain, low noise, simple bias systems, relative immunity from

thermal runaway, and the ability to withstand severely mismatched loads without suffering damage. Power output can be varied over a wide range with a low power dc control signal.

### **DC BIAS**

The MRF275G is an enhancement mode FET and, therefore, does not conduct when drain voltage is applied. Drain current flows when a positive voltage is applied to the gate. RF power FETs require forward bias for optimum performance. The value of quiescent drain current ( $I_{DQ}$ ) is not critical for many applications. The MRF275G was characterized at  $I_{DQ} = 100$  mA, each side, which is the suggested minimum value of  $I_{DQ}$ . For special applications such as linear amplification,  $I_{DQ}$  may have to be selected to optimize the critical parameters.

The gate is a dc open circuit and draws no current. Therefore, the gate bias circuit may be just a simple resistive divider network. Some applications may require a more elaborate bias system.

### **GAIN CONTROL**

Power output of the MRF275G may be controlled from its rated value down to zero (negative gain) by varying the dc gate voltage. This feature facilitates the design of manual gain control, AGC/ALC and modulation systems.

The RF MOSFET Line  
**RF Power**  
**Field-Effect Transistor**  
**N-Channel Enhancement-Mode**

Designed for broadband commercial and military applications using single ended circuits at frequencies to 500 MHz. The high power, high gain and broadband performance of this device makes possible solid state transmitters for FM broadcast or TV channel frequency bands.

- Guaranteed Performance @ 500 MHz, 28 Vdc  
Output Power — 100 Watts  
Power Gain — 8.8 dB Typ  
Efficiency — 55% Typ
- 100% Ruggedness Tested At Rated Output Power
- Low Thermal Resistance
- Low  $C_{RSS}$  — 17 pF Typ @  $V_{DS} = 28$  Volts
- S-Parameters Available for Download into Frequency Domain Simulators.

## RF POWER MOSFET CONSIDERATIONS

### MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between the terminals. The metal oxide gate structure determines the capacitors from gate-to-drain ( $C_{gd}$ ), and gate-to-source ( $C_{gs}$ ). The PN junction formed during the fabrication of the FET results in a junction capacitance from drain-to-source ( $C_{ds}$ ).

These capacitances are characterized as input ( $C_{iSS}$ ), output ( $C_{oSS}$ ) and reverse transfer ( $C_{rSS}$ ) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The  $C_{iSS}$  can be specified in two ways:

1. Drain shorted to source and positive voltage at the gate.
2. Positive voltage of the drain in respect to source and zero volts at the gate. In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

### DRAIN CHARACTERISTICS

One figure of merit for a FET is its static resistance in the full-on condition. This on-resistance,  $V_{DS(on)}$ , occurs in the linear region of the output characteristic and is specified under specific test conditions for gate-source voltage and drain current. For MOSFETs,  $V_{DS(on)}$  has a positive temperature coefficient and constitutes an important design consideration at high temperatures, because it contributes to the power dissipation within the device.

### GATE CHARACTERISTICS

The gate of the FET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of  $10^9$  ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage slightly in excess of the gate-to-source threshold voltage,  $V_{GS(th)}$ .

**Gate Voltage Rating** — Never exceed the gate voltage rating. Exceeding the rated  $V_{GS}$  can result in permanent damage to the oxide layer in the gate region.

**Gate Termination** — The gates of these devices are essentially capacitors. Circuits that leave the gate open-circuited or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.

**Gate Protection** — These devices do not have an internal monolithic zener diode from gate-to-source. If gate protection is required, an external zener diode is recommended.

Using a resistor to keep the gate-to-source impedance low also helps damp transients and serves another important function. Voltage transients on the drain can be coupled to the gate through the parasitic gate-drain capacitance. If the gate-to-source impedance and the rate of voltage change on the drain are both high, then the signal coupled to the gate may be large enough to exceed the gate-threshold voltage and turn the device on.

### HANDLING CONSIDERATIONS

When shipping, the devices should be transported only in antistatic bags or conductive foam. Upon removal from the packaging, careful handling procedures should be adhered to. Those handling the devices should wear grounding straps and devices not in the antistatic packaging should be kept in metal tote bins. MOSFETs should be handled by the case and not by the leads, and when testing the device, all leads should make good electrical contact before voltage is applied. As a final note, when placing the FET into the system it is designed for, soldering should be done with a grounded iron.

### DESIGN CONSIDERATIONS

The MRF275L is a RF power N-channel enhancement mode field-effect transistor (FETs) designed for HF, VHF and UHF power amplifier applications. Motorola FETs feature a vertical structure with a planar design.

Motorola Application Note AN211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

The major advantages of RF power FETs include high gain, low noise, simple bias systems, relative immunity from thermal runaway, and the ability to withstand severely mismatched loads without suffering damage. Power output can be varied over a wide range with a low power dc control signal.

### DC BIAS

The MRF275L is an enhancement mode FET and, therefore, does not conduct when drain voltage is applied. Drain current flows when a positive voltage is applied to the gate. RF power FETs require forward bias for optimum performance. The value of quiescent drain current ( $I_{DQ}$ ) is not critical for many applications. The MRF275L was characterized at  $I_{DQ} = 100$  mA, each side, which is the suggested minimum value of  $I_{DQ}$ . For special applications such as linear amplification,  $I_{DQ}$  may have to be selected to optimize the critical parameters.

The gate is a dc open circuit and draws no current. Therefore, the gate bias circuit may be just a simple resistive divider network. Some applications may require a more elaborate bias system.

### GAIN CONTROL

Power output of the MRF275L may be controlled from its rated value down to zero (negative gain) by varying the dc gate voltage. This feature facilitates the design of manual gain control, AGC/ALC and modulation systems.

The RF Sub-Micron MOSFET Line

N-Channel Enhancement-Mode Lateral MOSFETs

**MRF282SR1\***  
**MRF282ZR1\***

\*To be introduced 1Q00.

Designed for class A and class AB PCN and PCS base station applications at frequencies up to 2600 MHz. Suitable for FM, TDMA, CDMA, and multicarrier amplifier applications.

- Specified Two-Tone Performance @ 2000 MHz, 26 Volts  
Output Power = 10 Watts (PEP)  
Power Gain = 11 dB  
Efficiency = 30%  
Intermodulation Distortion = -28 dBc
- Specified Single-Tone Performance @ 2000 MHz, 26 Volts  
Output Power = 10 Watts (CW)  
Power Gain = 11 dB  
Efficiency = 40%
- Characterized with Series Equivalent Large-Signal Impedance Parameters
- S-Parameter Characterization at High Bias Levels
- Excellent Thermal Stability
- Capable of Handling 10:1 VSWR, @ 26 Vdc, 2000 MHz, 10 Watts (CW) Output Power
- Gold Metallization for Improved Reliability
- Available in Tape and Reel. R1 Suffix = 500 Units per 12 mm, 7 inch Reel.
- LDMOS Models and Circuit Board Artwork Available at:

**Figure 11. Power Gain versus Output Power**

Figure 12. Class A DC Safe Operating Area

Figure 13. Capacitance versus Drain Source Voltage

Figure 14. Class A Third Order Intercept Point

Figure 15. Performance in Broadband Circuit

This graph displays calculated MTBF in hours x ampere<sup>2</sup> drain current. Life tests at elevated temperature have correlated to better than  $\pm 10\%$  of the theoretical prediction for metal failure. Divide MTBF factor by  $I_D^2$  for MTBF in a particular application.

Figure 16. MTBF Factor versus Junction Temperature

$V_{CC} = 26 \text{ V}$ ,  $I_{CQ} = 75 \text{ mA}$ ,  $P_{out} = 10 \text{ W (PEP)}$

f MHz	$Z_{in}(1)$ $\Omega$	$Z_{OL}^*$ $\Omega$
1800	$2.1 + j1.0$	$3.8 - j0.15$
1860	$2.05 + j1.15$	$3.77 - j0.13$
1900	$2.0 + j1.2$	$3.75 - j0.1$
1960	$1.9 + j1.4$	$3.65 + j0.1$
2000	$1.85 + j1.6$	$3.55 + j0.2$

$Z_{in}(1)$  = Complex conjugate of source impedance.

$Z_{OL}^*$  = Conjugate of the optimum load impedance at given output power, voltage, IMD, bias current and frequency.

**Figure 17. Series Equivalent Input and Output Impedance**

The RF Sub-Micron MOSFET Line  
**RF Power Field Effect Transistors**  
N-Channel Enhancement-Mode Lateral MOSFETs

Designed for PCN and PCS base station applications at frequencies from 1000 to 2600 MHz. Suitable for FM, TDMA, CDMA, and multicarrier amplifier applications. To be used in class A and class AB for PCN-PCS/cellular radio and wireless local loop.

- Specified Two-Tone Performance @ 2000 MHz, 26 Volts  
Output Power = 30 Watts (PEP)  
Power Gain = 9 dB  
Efficiency = 30%  
Intermodulation Distortion = -29 dBc
- Typical Single-Tone Performance at 2000 MHz, 26 Volts  
Output Power = 30 Watts (CW)  
Power Gain = 9.5 dB  
Efficiency = 45%
- Characterized with Series Equivalent Large-Signal Impedance Parameters
- S-Parameter Characterization at High Bias Levels
- Excellent Thermal Stability
- Capable of Handling 10:1 VSWR, @ 26 Vdc, 2000 MHz, 30 Watts (CW) Output Power
- MRF284SR1 Is Available in Tape and Reel. R1 Suffix = 500 Units per 12 mm, 7 inch Reel.
- LDMOS Models, Test Fixture, Reference Design and Circuit Board Artwork

## TYPICAL CHARACTERISTICS

Figure 14. 1.92–2.0 GHz Broadband Circuit Performance

This graph displays calculated MTBF in hours  $\times$  ampere<sup>2</sup> drain current. Life tests at elevated temperature have correlated to better than  $\pm 10\%$  of the theoretical prediction for metal failure. Divide MTBF factor by  $I_D^2$  for MTBF in a particular application.

Figure 15. MTBF Factor versus Junction Temperature

$V_{CC} = 26 \text{ V}$ ,  $I_{CQ} = 200 \text{ mA}$ ,  $P_{out} = 15 \text{ W}_{avg}$

f MHz	$Z_{in}(1)$ Ohms	$Z_{OL}^*$ Ohms
1800	$1.0 + j0.4$	$2.1 - j0.4$
1860	$1.0 + j0.8$	$2.2 + j0.2$
1900	$1.0 + j1.1$	$2.3 + j0.5$
1960	$1.0 + j1.4$	$2.5 + j0.9$
2000	$1.0 + j2.3$	$2.6 + j0.92$

$Z_{in}(1)$  = Complex conjugate of source impedance.

$Z_{OL}^*$  = Conjugate of the optimum load impedance at given output power, voltage, bias current and frequency.

LATERAL N-CHANNEL  
BROADBAND  
RF POWER MOSFETS

## The RF MOSFET Line

## RF Power

## Field Effect Transistors

## N-Channel Enhancement-Mode Lateral MOSFETs

Designed for broadband commercial and industrial applications at frequencies from 470 – 860 MHz. The high gain and broadband performance of this device makes it ideal for large-signal, common source amplifier applications in 28 volt transmitter equipment.

- Guaranteed CW Performance at 860 MHz, 28 Volts, Narrowband Fixture  
Output Power – 60 Watts  
Power Gain – 13 dB  
Efficiency – 50%
- Typical Performance at 860 MHz, 28 Volts, Broadband Push-Pull Fixture  
Output Power – 100 Watts (PEP)  
Power Gain – 11.2 dB  
Efficiency – 40%  
IMD – -30 dBc
- Excellent Thermal Stability
- 100% Tested for Load Mismatch Stress at All Phase Angles with 5:1 VSWR @ 28 Vdc, 860 MHz, 60 Watts CW

**Figure 11. Broadband Efficiency versus Output Power**

## The RF Line

# NPN Silicon Push-Pull RF Power Transistor

Designed primarily for wideband large-signal output and driver amplifier stages in the 30 to 500 MHz frequency range.

- Specified 28 Volt, 400 MHz Characteristics —  
Output Power = 125 W  
Typical Gain = 10 dB  
Efficiency = 55% (Typ)
- Built-In Input Impedance Matching Networks for Broadband Operation
- Push-Pull Configuration Reduces Even Numbered Harmonics
- Gold Metallization System for High Reliability
- 100% Tested for Load Mismatch
- Circuit board photomaster available upon request by contacting RF Tactical Marketing in Phoenix, AZ.

The MRF392 is two transistors in a single package with separate base and collector leads and emitters common. This arrangement provides the designer with a space saving device capable of operation in a push-pull configuration.

### PUSH-PULL TRANSISTORS

### MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Collector-Emitter Voltage	$V_{CEO}$	30	Vdc
Collector-Base Voltage	$V_{CBO}$	60	Vdc
Emitter-Base Voltage	$V_{EBO}$	4.0	Vdc
Collector Current — Continuous	$I_C$	16	Adc
Total Device Dissipation @ $T_C = 25^\circ\text{C}$ (1) Derate above $25^\circ\text{C}$	$P_D$	270 1.54	Watts W/ $^\circ\text{C}$
Storage Temperature Range	$T_{stg}$	-65 to +150	$^\circ\text{C}$
Junction Temperature	$T_J$	200	$^\circ\text{C}$

### THERMAL CHARACTERISTICS

Characteristic	Symbol	Max	Unit
Thermal Resistance, Junction to Case	$R_{\theta JC}$	0.65	$^\circ\text{C}/\text{W}$

NOTE:

1. This device is designed for RF operation. The total device dissipation rating applies only when the device is operated as an RF push-pull amplifier.

**MRF858S**

Designed for 24 Volt UHF large-signal, common emitter, class A linear amplifier applications in industrial and commercial equipment operating in the range of 800–960 MHz.

- Specified for  $V_{CE} = 24$  Vdc,  $I_C = 0.5$  Adc Characteristics  
Output Power = 3.6 Watts CW  
Minimum Power Gain = 11 dB  
Minimum ITO = +44.5 dBm  
Typical Noise Figure = 6 dB
- Characterized with Small-Signal S-Parameters and Series Equivalent Large-Signal Parameters from 800–960 MHz
- Silicon Nitride Passivated
- 100% Tested for Load Mismatch Stress at All Phase Angles with 30:1 VSWR @ 24 Vdc,  $I_C = 0.5$  Adc and Rated Output Power
- Will Withstand RF Input Overdrive of 0.85 W CW
- Gold Metallized, Emitter Ballasted for Long Life and Resistance to Metal Migration
- Circuit board photomaster available upon request by contacting RF Tactical Marketing in Phoenix, AZ.

The RF Line  
**NPN Silicon**  
**RF Power Transistor**

Designed for 24 Volt UHF large-signal, common emitter, class-AB linear amplifier applications in industrial and commercial FM/AM equipment operating in the range 800-970 MHz.

- Specified 24 Volt, 900 MHz Characteristics
  - Output Power = 30 Watts
  - Minimum Gain = 10 dB @ 900 MHz, class-AB
  - Minimum Efficiency = 30% @ 900 MHz, 30 Watts (PEP)
  - Maximum Intermodulation Distortion -30 dBc @ 30 Watts (PEP)
- Characterized with Series Equivalent Large-Signal Parameters from 800 to 960 MHz
- Silicon Nitride Passivated
- 100% Tested for Load Mismatch Stress at all Phase Angles with 5:1 VSWR @ 26 Vdc, and Rated Output Power
- Gold Metalized, Emitter Ballasted for Long Life and Resistance to Metal-Migration
- Circuit board photomaster available upon request by contacting RF Tactical Marketing in Phoenix, AZ.

## NPN Silicon Low Noise Transistors

Motorola's MRF949 is a high performance NPN transistor designed for use in high gain, low noise small-signal amplifiers. The MRF949 is well suited for low voltage wireless applications. This device features a 9.0 GHz DC current gain-bandwidth product with excellent linearity.

- Low Noise Figure,  $NF_{min} = 1.4$  dB (Typ) @ 1.0 GHz, 8.0 V, 3.0 mA
- High Current Gain-Bandwidth Product,  $f_T = 9.0$  GHz, 6.0 V, 15 mA
- Maximum Stable Gain, 19 dB @ 1.0 GHz, 6.0 V, 10 mA
- Output Third Order Intercept, Output  $IP_3 = 29$  dBm @ 1.0 GHz, 6.0 V, 10 mA
- Fully Ion-Implanted with Gold Metallization and Nitride Passivation

### LOW NOISE TRANSISTORS

$f_T = 9.0$  GHz  
 $NF_{min} = 1.4$  dB  
 $I_{C_{MAX}} = 50$  mA  
 $V_{CEO} = 10$  V

### SEMICONDUCTOR TECHNICAL DATA

### MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Collector-Emitter Voltage	$V_{CEO}$	10	Vdc
Collector-Base Voltage	$V_{CB0}$	20	Vdc
Emitter-Base Voltage	$V_{EBO}$	1.5	Vdc
Power Dissipation @ $T_C = 75^\circ\text{C}$ Derate linearly above $T_C = 75^\circ\text{C}$ at	$P_{D(max)}$	0.144 1.92	W mW/ $^\circ\text{C}$
Collector Current – Continuous [Note 3]	$I_C$	50	mA

<b>OFF CHARACTERISTICS</b> [Note 1]					
Collector–Emitter Breakdown Voltage (I <sub>C</sub> = 0.1 mA, I <sub>B</sub> = 0)	V <sub>(BR)CEO</sub>	10	12	–	Vdc
Collector–Base Breakdown Voltage (I <sub>C</sub> = 0.1 mA, I <sub>E</sub> = 0)	V <sub>(BR)CBO</sub>	20	23	–	Vdc
Emitter Cutoff Current (V <sub>EB</sub> = 1.0 V, I <sub>C</sub> = 0)	I <sub>EBO</sub>	–	–	0.1	μA
Collector Cutoff Current (V <sub>CB</sub> = 10 V, I <sub>E</sub> = 0)	I <sub>CBO</sub>	–	–	0.1	μA

## ON CHARACTERISTICS

DC Current Gain (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA)	h <sub>FE</sub>	50	–	–	–
--	-----------------	----	---	---	---

## DYNAMIC CHARACTERISTICS

Collector–Base Capacitance (V <sub>CB</sub> = 1.0 V, I <sub>E</sub> = 0, f = 1.0 MHz) (V <sub>CB</sub> = 5.0 V, I <sub>E</sub> = 0, f = 1.0 MHz)	C <sub>cb</sub>	–	0.4 0.3	–	pF
Current–Gain Bandwidth Product (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 30 mA, f = 1.0 GHz)	f <sub>t</sub>	–	9.0	–	GHz

## PERFORMANCE CHARACTERISTICS

Insertion Gain (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	S <sub>21</sub>   <sup>2</sup>	–	7.0 15	–	dB
Maximum Unilateral Gain [Note 2] (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	G <sub>Umax</sub>	–	13 17	–	dB
Maximum Stable Gain and/or Maximum Available Gain [Note 3] (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	MSG MAG	–	12 18	–	dB
Noise Figure – Minimum (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz)	N <sub>Fmin</sub>	–	1.6 1.4	–	dB
Noise Resistance (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz)	R <sub>N</sub>	–	24 19	–	Ω
Associated Gain at Minimum NF (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz)	G <sub>NF</sub>	–	10 15	–	dB
Output Power at 1.0 dB Gain Compression [Note 4] (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	P <sub>1dB</sub>	–	13	–	dBm
Output Third Order Intercept [Note 4] (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	OIP <sub>3</sub>	–	28	–	dBm

**NOTES:** 1. Pulse width ≤300 μs, duty cycle ≤2% pulsed.

2. Maximum unilateral gain is:

$$G_{Umax} = \frac{|S_{21}|^2}{(1-|S_{11}|^2)(1-|S_{22}|^2)}$$

3. Maximum Available Gain and Maximum Stable Gain are defined by the K factor as follows:

$$MAG = \left| \frac{S_{21}}{S_{12}} \left( K \pm \sqrt{K^2 - 1} \right) \right|, \text{ if } K > 1, \quad MSG = \left| \frac{S_{21}}{S_{12}} \right|, \text{ if } K < 1$$

4. Z<sub>in</sub> = 50 Ω and Z<sub>out</sub> matched for optimum IP<sub>3</sub>.

# NPN Silicon Low Noise Transistors

Motorola's MRF959 is a high performance NPN transistor designed for use in high gain, low noise small-signal amplifiers. The MRF959 is well suited for low voltage applications. This device features a 9.0 GHz DC current gain-bandwidth product with excellent linearity.

- Low Noise Figure,  $NF_{min} = 1.3$  dB (Typ) @ 1.0 GHz, 6.0 V, 5.0 mA
- High Current Gain-Bandwidth Product,  $f_T = 9.0$  GHz, 6.0 V, 30 mA
- Maximum Stable Gain, 17 dB @ 1.0 GHz, 6.0 V, 10 mA
- Output Third Order Intercept, Output  $IP_3 = 30$  dBm @ 1.0 GHz, 6.0 V, 30 mA
- Fully Ion-Implanted with Gold Metallization and Nitride Passivation

## MRF959T1

### LOW NOISE TRANSISTORS

$f_T = 9.0$  GHz  
 $NF_{min} = 1.3$  dB  
 $I_{C_{MAX}} = 100$  mA  
 $V_{CEO} = 10$  V

**SEMICONDUCTOR  
TECHNICAL DATA**

### MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Collector-Emitter Voltage	$V_{CEO}$	10	Vdc
Collector-Base Voltage	$V_{CBO}$	20	Vdc
Emitter-Base Voltage	$V_{EBO}$	1.5	Vdc
Power Dissipation @ $T_C = 75^\circ\text{C}$ Derate linearly above $T_C = 75^\circ\text{C}$ at	$PD(max)$	0.15 2.0	W mW/ $^\circ\text{C}$
Collector Current – Continuous [Note 3]	$I_C$	100	mA
Storage Temperature	$T_{stg}$	-55 to 150	$^\circ\text{C}$
Maximum Junction Temperature	$T_{J(max)}$	150	$^\circ\text{C}$

**NOTES:** 1. Meets Human Body Model (HBM)  $\leq 300$  V and Machine Model (MM)  $\leq 75$  V.  
 2. ESD data available upon request.  
 3. For MTBF >10 years.

### THERMAL CHARACTERISTIC

Characteristics	Symbol	Max	Unit
Thermal Resistance, Junction-to-Case	$R_{\theta JC}$	500	$^\circ\text{C/W}$

**NOTE:** To calculate the junction temperature use  $T_J = (P_D \times R_{\theta JC}) + T_C$ . The case temperature measured on collector lead adjacent to the package body.

## ELECTRICAL CHARACTERISTICS (T<sub>C</sub> = 25°C, unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
<b>OFF CHARACTERISTICS</b> [Note 1]					
Collector–Emitter Breakdown Voltage (I <sub>C</sub> = 0.1 mA, I <sub>B</sub> = 0)	V <sub>(BR)CEO</sub>	10	13	–	Vdc
Collector–Base Breakdown Voltage (I <sub>C</sub> = 0.1 mA, I <sub>E</sub> = 0)	V <sub>(BR)CBO</sub>	20	25	–	Vdc
Emitter Cutoff Current (V <sub>EB</sub> = 1.0 V, I <sub>C</sub> = 0)	I <sub>EBO</sub>	–	–	0.1	μA
Collector Cutoff Current (V <sub>CB</sub> = 10 V, I <sub>E</sub> = 0)	I <sub>CBO</sub>	–	–	0.1	μA
<b>ON CHARACTERISTICS</b> [Note 1]					
DC Current Gain (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA)	h <sub>FE</sub>	75	–	150	–
<b>DYNAMIC CHARACTERISTICS</b>					
Collector–Base Capacitance (V <sub>CB</sub> = 1.0 V, I <sub>E</sub> = 0, f = 1.0 MHz) (V <sub>CB</sub> = 5.0 V, I <sub>E</sub> = 0, f = 1.0 MHz)	C <sub>cb</sub>	–	0.63 0.44	–	pF
Current Gain – Bandwidth Product (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 30 mA, f = 1.0 GHz)	f <sub>t</sub>	–	9.0	–	GHz
<b>PERFORMANCE CHARACTERISTICS</b>					
Insertion Gain (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	S <sub>21</sub>   <sup>2</sup>	–	4.0 14	–	dB
Maximum Unilateral Gain [Note 2] (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	G <sub>Umax</sub>	–	9.0 15	–	dB
Maximum Stable Gain and/or Maximum Available Gain [Note 3] (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	MSG MAG	–	10 17	–	dB
Noise Figure – Minimum (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz)	NF <sub>min</sub>	–	1.6 1.3	–	dB
Noise Resistance (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz)	R <sub>N</sub>	–	14 9.0	–	Ω
Associated Gain at Minimum NF (V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz) (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 5.0 mA, f = 1.0 GHz)	G <sub>NF</sub>	–	8.0 13	–	dB
Output Power at 1.0 dB Gain Compression [Note 4] (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	P <sub>1dB</sub>	–	12	–	dBm
Output Third Order Intercept [Note 4] (V <sub>CE</sub> = 6.0 V, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	OIP <sub>3</sub>	–	26	–	dBm

**NOTES:** 1. Pulse width ≤300 μs, duty cycle ≤2% pulsed.

2. Maximum unilateral gain is:

$$G_{Umax} = \frac{|S_{21}|^2}{(1-|S_{11}|^2)(1-|S_{22}|^2)}$$

3. Maximum Available Gain and Maximum Stable Gain are defined by the K factor as follows:

$$MAG = \left| \frac{S_{21}}{S_{12}} \left( K \pm \sqrt{K^2 - 1} \right) \right|, \text{ if } K > 1, \text{ MSG} = \left| \frac{S_{21}}{S_{12}} \right|, \text{ if } K < 1$$

4. Z<sub>in</sub> = 50 Ω and Z<sub>out</sub> matched for small signal maximum gain.

## Advance Information

# NPN Silicon Low Noise Transistor

The MRF1047T1 is fabricated utilizing Motorola's latest 12 GHz  $f_T$  discrete bipolar silicon process. The minimum noise figure is 1.0 dB at  $V_{CE} = 3.0$  V and  $I_C = 3.0$  mA. The noise performance of the MRF1047T1 at low bias makes this device the ideal choice in high gain, low noise applications. This device is well suited for low-voltage, low-current, front-end applications, for use in pagers, cellular and cordless phones, and other portable wireless systems.

The MRF1047T1 has 16 emitter fingers, with self-aligned and enhanced processing, resulting in a high  $f_T$ , low operating current transistor with reduced parasitics. The MRF1047T1 is fully-ion implanted with gold metallization and nitride passivation for maximum device reliability, performance and uniformity.

- Low Noise Figure,  $NF_{min} = 1.0$  dB (Typ) @ 1.0 GHz, 3.0 V and 3.0 mA
- High Current Gain-Bandwidth Product,  $f_T = 12$  GHz, 3.0 V @ 15 mA
- Maximum Stable Gain, 17 dB @ 1.0 GHz, 3.0 V and 10 mA
- Output Third Order Intercept,  $OIP_3 = 26$  dBm @ 1.0 GHz 3.0 V and 15 mA
- Fully Ion-Implanted with Gold Metallization and Nitride Passivation

### MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Collector-Emitter Voltage	$V_{CEO}$	5.0	Vdc
Collector-Base Voltage	$V_{CBO}$	12	Vdc
Emitter-Base Voltage	$V_{EBO}$	2.5	Vdc
Collector Current – Continuous [Note 3]	$I_C$	45	mAdc
Power Dissipation @ $T_C = 75^\circ\text{C}$ Derate Linearly above $T_C = 75^\circ\text{C}$ at	$P_{D(max)}$	0.172 2.3	W mW/ $^\circ\text{C}$
Storage Temperature Range	$T_{stg}$	-55 to 150	$^\circ\text{C}$
Maximum Junction Temperature	$T_{J(max)}$	150	$^\circ\text{C}$

**NOTES:** 1. Meets Human Body Model (HBM)  $\leq 300$  V and Machine Model (MM)  $\leq 75$  V.  
2. ESD data available upon request.  
3. For MTBF >10 years.

### THERMAL CHARACTERISTIC

Characteristics	Symbol	Max	Unit
Thermal Resistance, Junction-to-Case	$R_{\theta JC}$	435	$^\circ\text{C/W}$

**NOTE:** To calculate the junction temperature use  $T_J = (P_D \times R_{\theta JC}) + T_C$ . The case temperature measured on collector lead adjacent to the package body.

# MRF1047T1

## RF NPN SILICON TRANSISTOR

$f_T = 12$  GHz  
 $NF_{min} = 1.0$  dB  
 $I_{C MAX} = 45$  mA  
 $V_{CEO} = 5.0$  V

## ELECTRICAL CHARACTERISTICS (T<sub>C</sub> = 25°C, unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
<b>OFF CHARACTERISTICS</b> [Note 1]					
Collector–Emitter Breakdown Voltage (I <sub>C</sub> = 0.1 mA, I <sub>B</sub> = 0)	V <sub>(BR)CEO</sub>	5.0	–	–	Vdc
Collector–Base Breakdown Voltage (I <sub>C</sub> = 0.1 mA, I <sub>E</sub> = 0)	V <sub>(BR)CBO</sub>	12	–	–	Vdc
Emitter–Base Breakdown Voltage (I <sub>E</sub> = 0.1 mA, I <sub>C</sub> = 0)	V <sub>(BR)CBO</sub>	2.5	–	–	Vdc
Collector Cutoff Current (V <sub>CB</sub> = 1.0 V, I <sub>E</sub> = 0)	I <sub>CBO</sub>	–	–	0.2	μA
Emitter Cutoff Current (V <sub>EB</sub> = 1.0 V, I <sub>C</sub> = 0)	I <sub>EBO</sub>	–	–	0.1	μA
<b>ON CHARACTERISTICS</b> [Note 1]					
DC Current Gain (V <sub>CE</sub> = 3.0 V, I <sub>C</sub> = 3.0 mA)	h <sub>FE</sub>	100	–	200	–
<b>DYNAMIC CHARACTERISTICS</b>					
Collector–Base Capacitance (V <sub>CB</sub> = 1.0 Vdc, I <sub>E</sub> = 0, f = 1.0 MHz)	C <sub>cb</sub>	–	0.4	–	pF
Current–Gain Bandwidth Product (V <sub>CE</sub> = 3.0 Vdc, I <sub>C</sub> = 15 mA, f = 1.0 GHz)	f <sub>t</sub>	–	12	–	GHz
<b>PERFORMANCE CHARACTERISTICS</b>					
Insertion Gain V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz V <sub>CE</sub> = 3.0 V, I <sub>C</sub> = 3.0 mA, f = 1.0 GHz	S <sub>21</sub>   <sup>2</sup>	– –	8.0 13	– –	dB
Maximum Stable Gain and/or Maximum Available Gain [Note 2] V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz V <sub>CE</sub> = 3.0 V, I <sub>C</sub> = 3.0 mA, f = 1.0 GHz	MSG, MAG	– –	11 16	– –	dB
Minimum Noise Figure V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz V <sub>CE</sub> = 3.0 V, I <sub>C</sub> = 3.0 mA, f = 1.0 GHz	NF <sub>min</sub>	– –	1.2 1.0	– –	dB
Associated Gain at Minimum NF V <sub>CE</sub> = 1.0 V, I <sub>C</sub> = 1.0 mA, f = 1.0 GHz V <sub>CE</sub> = 3.0 V, I <sub>C</sub> = 3.0 mA, f = 1.0 GHz	G <sub>NF</sub>	– –	10 13	– –	dB
Output Power at 1.0 dB Gain Compression [Note 3] (V <sub>CE</sub> = 3.0 V, I <sub>C</sub> = 3.0 mA, f = 1.0 GHz)	P <sub>1dB</sub>	–	0.5	–	dBm
Output Third Order Intercept [Note 3] (V <sub>CE</sub> = 3.0 V, I <sub>C</sub> = 3.0 mA, f = 1.0 GHz)	OIP <sub>3</sub>	–	22	–	dBm

**NOTES:** 1. Pulse width ≤300 μs, duty cycle ≤2% pulsed.

2. Maximum Available Gain and Maximum Stable Gain are defined by the K factor as follows:

$$\text{MAG} = \left| \frac{S_{21}}{S_{12}} \left( K \pm \sqrt{K^2 - 1} \right) \right|, \text{ if } K > 1, \text{ MSG} = \left| \frac{S_{21}}{S_{12}} \right|, \text{ if } K < 1$$

3. Z<sub>in</sub> = 50 Ω and Z<sub>out</sub> matched for optimum IP3.

**MRF6404**

**30 W, 1.88 GHz**  
**RF POWER TRANSISTOR**  
**NPN SILICON**

**CASE 395C-01, STYLE 1**

The MRF6404 is designed for 26 volts microwave large signal, common emitter, class AB linear amplifier applications operating in the range 1.8 to 2.0 GHz.

- Specified 26 Volts, 1.88 GHz Characteristics  
Output Power — 30 Watts  
Gain — 7.5 dB Min @ 30 Watts  
Efficiency — 38% Min @ 30 Watts
- Characterized with Series Equivalent Large-Signal Parameters from 1.8 to 2.0 GHz
- To be used in Class AB for DCS1800 and PCS1900/Cellular Radio
- Gold Metallized, Emitter Ballasted for Long Life and Resistance to Metal Migration

**MAXIMUM RATINGS**

Rating	Symbol	Value	Unit
Collector-Emitter Voltage	$V_{CEO}$	24	Vdc
Collector-Emitter Voltage	$V_{CES}$	60	Vdc
Emitter-Base Voltage	$V_{EBO}$	4	Vdc
Collector-Current — Continuous	$I_C$	10	Adc
Total Device Dissipation @ $T_C = 25^\circ\text{C}$ Derate above $25^\circ\text{C}$	$P_D$	125 0.71	Watts W/ $^\circ\text{C}$
Storage Temperature Range	$T_{stg}$	-65 to +150	$^\circ\text{C}$
Operating Junction Temperature	$T_J$	200	$^\circ\text{C}$

**THERMAL CHARACTERISTICS**

Characteristic	Symbol	Max	Unit
Thermal Resistance, Junction to Case (1)	$R_{\theta JC}$	1.4	$^\circ\text{C}/\text{W}$

**ELECTRICAL CHARACTERISTICS** ( $T_C = 25^\circ\text{C}$  unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
----------------	--------	-----	-----	-----	------

**OFF CHARACTERISTICS**

Collector-Emitter Breakdown Voltage ( $I_C = 50\text{ mA}$ , $I_B = 0$ )	$V_{(BR)CEO}$	24	29	—	Vdc
Emitter-Base Breakdown Voltage ( $I_E = 10\text{ mAdc}$ )	$V_{(BR)EBO}$	4	5	—	Vdc
Collector-Base Breakdown Voltage ( $I_C = 50\text{ mAdc}$ )	$V_{(BR)CES}$	60	68	—	Vdc
Collector-Base Breakdown Voltage ( $I_C = 50\text{ mAdc}$ , $R_{BE} = 75\ \Omega$ )	$V_{(BR)CER}$	40	56	—	Vdc
Collector Cutoff Current ( $V_{CE} = 30\text{ V}$ , $V_{BE} = 0$ )	$I_{CES}$	—	—	10	mA

**ON CHARACTERISTICS**

--	----------	----	----	-----	---

(1) Thermal resistance is determined under specified RF operating condition.

**ELECTRICAL CHARACTERISTICS — continued** ( $T_C = 25^\circ\text{C}$  unless otherwise noted)

Characteristic	Symbol	Min	Typ	Max	Unit
<b>DYNAMIC CHARACTERISTICS</b>					
Output Capacitance ( $V_{CB} = 26\text{ V}$ , $I_E = 0$ , $f = 1\text{ MHz}$ ) For information only. This part is collector matched.	$C_{ob}$	30	38	—	pF
<b>FUNCTIONAL TESTS</b>					
Common-Emitter Amplifier Power Gain ( $V_{CC} = 26\text{ V}$ , $P_{out} = 30\text{ W}$ , $I_{CQ} = 150\text{ mA}$ , $f = 1.88\text{ GHz}$ )	$G_{pe}$	7.5	8.5	—	dB
Common-Emitter Amplifier Power Gain ( $V_{CC} = 26\text{ V}$ , $P_{out} = 28\text{ W}$ , $I_{CQ} = 150\text{ mA}$ ) ( $f = 1.99\text{ GHz}$ )	$G_{pe}$	7	8	—	dB
Collector Efficiency ( $V_{CC} = 26\text{ V}$ , $P_{out} = 30\text{ W}$ , $f = 1.88\text{ GHz}$ ) ( $V_{CC} = 26\text{ V}$ , $P_{out} = 28\text{ W}$ , $f = 1.99\text{ GHz}$ )	$\eta$	38 35	43 40	— —	%
Output Power at 1 dBc ( $V_{CC} = 26\text{ V}$ , $f = 1.88\text{ GHz}$ ) ( $V_{CC} = 26\text{ V}$ , $f = 1.99\text{ GHz}$ )	$P_{1dBc}$	30 28	35 33	— —	Watts
Output Mismatch Stress: VSWR = 3:1 (all phase angles) ( $V_{CC} = 26\text{ Vdc}$ , $P_{out} = 25\text{ W}$ , $I_{CQ} = 150\text{ mA}$ , $f = 1.88\text{ GHz}$ )	$\Psi$	No Degradation in Output Power			

**DCS EVALUATION**

f (GHz)	$Z_{in}$ ( $\Omega$ )	$Z_{OL}^*$ ( $\Omega$ )
1.8	$4.3 + j6.1$	$2.7 - j1.0$
1.85	$4.6 + j5.3$	$2.9 + j0.3$
1.9	$4.8 + j5.0$	$3.0 + j1.2$

$Z_{OL}^*$ : Conjugate of optimum load impedance into which the device operates at a given output power, voltage, current and frequency.

**Figure 1. Input and Output Impedances with Circuit Tuned for Maximum Gain  
@  $V_{CC} = 26\text{ V}$ ,  $I_{CQ} = 150\text{ mA}$ ,  $P_{out} = 30\text{ W}$**

# Silicon Lateral FET, N-Channel Enhancement-Mode MOSFET

Designed for use in low voltage, moderate power amplifiers such as portable analog and digital cellular radios and PC RF modems.

- Performance Specifications at 900 MHz, 4.8 V
  - Output Power = 36 dBm Typ
  - Power Gain = 10 dB Typ
  - Efficiency = 65% Typ
- Guaranteed Ruggedness at Load VSWR = 10:1
- New Plastic Surface Mount Package

## MRF9482T1

**HIGH FREQUENCY  
POWER TRANSISTOR  
LDMOS FET  
36 dBm, 900 MHz**

**SEMICONDUCTOR

## The RF Line Microwave Power Transistor

... designed for CW and long pulsed common base amplifier applications, such as JTIDS and Mode S, in the 0.96 to 1.215 GHz frequency range at high overall duty cycles.

- Guaranteed Performance @ 1.215 GHz, 28 Vdc  
Output Power = 5.0 Watts CW  
Minimum Gain = 8.5 dB, 10.3 dB (Typ)
- RF Performance Curves given for 28 Vdc and 36 Vdc Operation
- 100% Tested for Load Mismatch at All Phase Angles with 10:1 VSWR
- Hermetically Sealed Industry Standard Package
- Silicon Nitride Passivated
- Gold Metallized, Emitter Ballasted for Long Life and Resistance to Metal Migration
- Internal Input Matching for Broadband Operation
- Circuit board photomaster available upon request by contacting RF Tactical Marketing in Phoenix, AZ.

## The RF Line Microwave Pulse Power Transistor

Designed for 1025–1150 MHz pulse common base amplifier applications such as TCAS, TACAN and Mode-S transmitters.

- Guaranteed Performance @ 1090 MHz  
Output Power = 500 Watts Peak  
Gain = 8.5 dB Min, 9.0 dB (Typ)
- 100% Tested for Load Mismatch at All Phase Angles with 10:1 VSWR
- Hermetically Sealed Industry Package
- Silicon Nitride Passivated
- Gold Metallized, Emitter Ballasted for Long Life and Resistance to Metal Migration
- Internal Input and Output Matching
- Characterized with 10  $\mu$ s, 1% Duty Cycle Pulses

The RF MOSFET Line  
**RF Power Field Effect Transistors**  
N-Channel Enhancement-Mode Lateral MOSFETs

Designed for PCN and PCS base station applications from frequencies up to 1.8 to 2.0 GHz. Suitable for FM, TDMA, CDMA and multicarrier amplifier applications. To be used in class AB for PCN-PCS/cellular radio and WLL applications. Specified for GSM1805 – 1880 MHz.

- Typical GSM Performance, Full Frequency Band (1805 – 1880 MHz)  
Power Gain — 13 dB (Typ) @ 60 Watts  
Efficiency — 45% (Typ) @ 60 Watts
- Internally Matched, Controlled Q, for Ease of Use
- High Gain, High Efficiency and High Linearity
- Integrated ESD Protection: Class 2 Human Body Model, Class M3 Machine Model
- Ease of Design for Gain and Insertion Phase Flatness
- Capable of Handling 10:1 VSWR, @ 26 Vdc, 60 Watts (CW) Output Power
- Excellent Thermal Stability

**RF Power Field Effect Transistors**  
N-Channel Enhancement-Mode Lateral MOSFETs

Designed for PCN and PCS base station applications from frequencies up to 1.8 to 2.0 GHz. Suitable for FM, TDMA, CDMA and multicarrier amplifier applications. To be used in class AB for PCN-PCS/cellular radio and WLL applications. Specified for GSM1930 – 1990 MHz.

- GSM Performance, Full Frequency Band (1930 – 1990 MHz)  
Power Gain — 13 dB (Typ) @ 60 Watts (CW)  
Efficiency — 45% (Typ) @ 60 Watts (CW)
- Internally Matched, Controlled Q, for Ease of Use
- High Gain, High Efficiency and High Linearity
- Integrated ESD Protection: Class 2 Human Body Model, Class M3 Machine Model
- Ease of Design for Gain and Insertion Phase Flatness
- Capable of Handling 10:1 VSWR, @ 26 Vdc, 60 Watts (CW) Output Power
- Excellent Thermal Stability

The RF MOSFET Line  
**RF Power Field Effect Transistors**  
N-Channel Enhancement-Mode Lateral MOSFETs

Designed for class AB PCN and PCS base station applications from 1.9 to 2.0 GHz. Suitable for CDMA, TDMA, GSM, and multicarrier amplifier applications.

- Typical CDMA Performance: 1990 MHz, 26 Volts  
IS-97 CDMA Pilot, Sync, Paging, Traffic Codes 8 Through 13  
Output Power — 9 Watts  
Power Gain — 10 dB  
Adjacent Channel Power —  
885 kHz: -47 dBc @ 30 kHz BW  
1.25 MHz: -55 dBc @ 12.5 kHz BW  
2.25 MHz: -55 dBc @ 1 MHz BW
- Internally Matched, Controlled Q, for Ease of Use
- High Gain, High Efficiency and High Linearity
- Integrated ESD Protection: Class 2 Human Body Model, Class M3 Machine Model
- Ease of Design for Gain and Insertion Phase Flatness
- Capable of Handling 10:1 VSWR, @ 26 Vdc, 1.93 GHz, 90 Watts (CW) Output Power
- Excellent Thermal Stability
- Characterized with Series Equivalent Large-Signal Impedance Parameters

## The RF Sub-Micron Bipolar Line RF Power Bipolar Transistor

Designed for broadband commercial and industrial applications at frequencies from 1800 to 2000 MHz. The high gain and broadband performance of this device makes it ideal for large-signal, common-emitter class AB amplifier applications. Suitable for frequency modulated, amplitude modulated and multi-carrier base station RF power amplifiers.

- Specified 26 Volts, 2.0 GHz, Class AB, Two-Tones Characteristics
  - Output Power — 30 Watts (PEP)
  - Power Gain — 9.8 dB
  - Efficiency — 34%
  - Intermodulation Distortion — -28 dBc
- Typical 26 Volts, 1.88 GHz, Class AB, CW Characteristics
  - Output Power — 30 Watts
  - Power Gain — 11 dB
  - Efficiency — 40%
  - Intermodulation Distortion — -30 dBc
- Excellent Thermal Stability
- Capable of Handling 3:1 VSWR @ 26 Vdc, 2000 MHz, 30 Watts (PEP) Output Power
- Characterized with Series Equivalent Large-Signal Impedance Parameters
- S-Parameter Characterization at High Bias Levels
- Designed for FM, TDMA, CDMA, and Multi-Carrier Applications

**Note:** Not suitable for class A operation.

## The RF Sub-Micron Bipolar Line RF Power Bipolar Transistors

The MRF20060R and MRF20060RS are designed for class AB broadband commercial and industrial applications at frequencies from 1800 to 2000 MHz. The high gain, excellent linearity and broadband performance of these devices make them ideal for large-signal, common emitter class AB amplifier applications. These devices are suitable for frequency modulated, amplitude modulated and multi-carrier base station RF power amplifiers.

- Guaranteed Two-tone Performance at 2000 MHz, 26 Volts  
Output Power — 60 Watts (PEP)  
Power Gain — 9 dB  
Efficiency — 33%  
Intermodulation Distortion — -30 dBc
- Characterized with Series Equivalent Large-Signal Impedance Parameters
- S-Parameter Characterization at High Bias Levels
- Excellent Thermal Stability
- Capable of Handling 3:1 VSWR @ 26 Vdc, 2000 MHz, 60 Watts (PEP) Output Power
- Designed for FM, TDMA, CDMA and Multi-Carrier Applications
- Test Fixtures Available at: <http://mot-sps.com/rf/designtds/>

**Note:** Not suitable for class A operation.

The RF MOSFET Line  
**RF Power Field Effect Transistors**  
N-Channel Enhancement-Mode Lateral MOSFETs

Designed for PCN and PCS base station applications from frequencies up to 2.1 to 2.2 GHz. Suitable for W-CDMA, CDMA, TDMA, GSM and multicarrier amplifier applications.

- Typical W-CDMA Performance: 2140 MHz, 28 Volts  
5 MHz Offset @ 4.096 MHz BW, 15 DTCH  
Output Power — 6.0 Watts  
Power Gain — 12.5 dB  
Drain Efficiency — 15%
- Internally Matched, Controlled Q, for Ease of Use
- High Gain, High Efficiency and High Linearity
- Integrated ESD Protection: Class 2 Human Body Model, Class M3 Machine Model
- Ease of Design for Gain and Insertion Phase Flatness
- Capable of Handling 10:1 VSWR, @ 28 Vdc, 2.11 GHz, 60 Watts (CW) Output Power
- Excellent Thermal Stability
- Characterized with Series Equivalent Large-Signal Impedance Parameters

## The RF Line NPN Silicon RF Power Transistor

The TPV8100B is designed for output stages in band IV and V TV transmitter amplifiers. It incorporates high value emitter ballast resistors, gold metallizations and offers a high degree of reliability and ruggedness.

Including double input and output matching networks, the TPV8100B features high impedances. It can easily operate in a full 470 MHz to 860 MHz bandwidth in a single and simple circuit.

- To be used class AB for TV band IV and V.
- Specified 28 Volts, 860 MHz Characteristics  
Output Power = 125 Watts (peak sync.)  
Output Power = 100 Watts (CW)  
Minimum Gain = 8.5 dB
- Specified 32 Volts, 860 MHz Characteristics  
Output Power = 150 Watts (peak sync.)
- Circuit board photomaster available upon request by contacting RF Tactical Marketing in Phoenix, AZ.

## Motorola RF Amplifier Modules

Motorola's RF portfolio includes many hybrid designs optimized to perform either in narrowband base station transmitter applications, or in broadband linear amplifiers. Motorola modules feature two or more active transistors (LDMOS, GaAs, or Bipolar die technology) and their associated 50 ohm matching networks. Circuit substrate and metallization have been selected for optimum performance and reliability. For PA designers, hybrid modules offer the benefits of small and less complex system designs, in less time and at a lower overall cost.

# Motorola RF Amplifier Modules/ICs

Complete amplifiers with 50 ohm input and output impedances are available for all popular base station transmitter systems, including GSM and CDMA, covering frequencies from 800 MHz up to 2.2 GHz.

## Base Stations

Designed for applications such as macrocell drivers and microcell output stage, these class AB amplifiers are ideal for GSM base station systems at 900, 1800 and 1900 MHz, with power requirements up to 16 watts.

**Table 1. Base Stations**

Device	Frequency MHz	P <sub>out</sub> Watts	Gain (Min) dB	Supply Voltage Volts	Class	System Application	Die Technology	Package/Style
MHVIC910L <sup>(46b)</sup>	921–960	10	22	26	AB	GSM900	LDMOS–IC	978/–
MHW1810–1	1805–1880	10	24	26	AB	GSM1800	LDMOS	301AW/1
MHW1810–2	1805–1880	10	32	26	AB	GSM1800	LDMOS	301AW/1

MHW1910–1	1930–1990	10	24	26	AB	GSM1900	LDMOS	301AW/1
MHW1915	1930–1990	15	29	26	AB	GSM1900	Silicon Bipolar	301AK/1

**Table 2. Base Station Drivers**

These 50 ohm amplifiers are recommended for modern multi–tone CDMA, TDMA and UMTS base station pre–driver applications. Their high third–order intercept point, tight phase and gain control, and excellent group delay characteristics make these devices ideal for use in high–power feedforward loops.

## Wideband Linear Amplifiers

**Table 1. Standard 50 Ohm Linear Hybrid**

This series of RF linear hybrid amplifier has been optimized for wideband, 50 ohm applications. These amplifiers were designed for multi-purpose RF applications where linearity, dynamic range and wide bandwidth are of primary concern. The MHL series utilizes a new case style that provides microstrip input and output connections.

Device	Frequency Band MHz	V <sub>CC</sub> (Nom.) Volts	I <sub>CC</sub> (Nom.) mA	Gain/Freq. (Typ) dB/MHz	Gain Flatness (Typ) ±dB	P <sub>1dB</sub> (Typ) dBm	3rd Order Intercept Point/Freq. (Typ) dBm/MHz	NF/Freq. (Typ) dB/MHz	Case/ Style

## The RF Line Cellular Band Linear Amplifiers

Designed for ultra-linear amplifier applications in 50 ohm systems operating in the cellular frequency band. A silicon FET Class A design provides outstanding linearity and gain. In addition, the excellent group delay and phase linearity characteristics are ideal for the most demanding analog or digital modulation systems, such as TDMA, CDMA or QPSK.

- Third Order Intercept: 47 dBm Typ
- Power Gain: 30.5 dB Typ (@ f = 880 MHz)
- Excellent Phase Linearity and Group Delay Characteristics
- Ideal for Feedforward Base Station Applications
- For Use in TDMA, CDMA, QPSK or Analog Systems

## The RF Line Cellular Band Linear Amplifier

Designed for ultra-linear amplifier applications in 50 ohm systems operating in the cellular frequency band. A silicon FET Class A design provides outstanding linearity and gain. In addition, the excellent group delay and phase linearity characteristics are ideal for the most demanding analog or digital modulation systems, such as TDMA and CDMA.

- Third Order Intercept: 49 dBm Typ
- Power Gain: 17.5 dB Typ (@ f = 880 MHz)
- Excellent Phase Linearity and Group Delay Characteristics
- Ideal for Feedforward Base Station Applications
- For Use in TDMA and CDMA Multi-Carrier Applications

## Wideband Amplifiers

**MHW1224**  
**MHW1244**

Designed specifically for broadband applications requiring low distortion characteristics. Specified for use as return amplifiers for mid-split and high-split 2-way cable TV systems. Features all gold metallization system.

- Guaranteed Broadband Power Gain @  $f = 5.0\text{--}200$  MHz
- Guaranteed Broadband Noise Figure @  $f = 5.0\text{--}175$  MHz
- Superior Gain, Return Loss and DC Current Stability with Temperature
- All Gold Metallization
- All Ion-Implanted Arsenic Emitter Transistor Chips with 6.0 GHz  $f_T$ 's
- Circuit Design Optimized for Good RF Stability Under High VSWR Load Conditions
- Transformers Designed to Insure Good Low Frequency Gain Stability versus Temperature

22-Channel FLAT (5.0–175 MHz) (2) (3)	$XM_{22}$	-62 Max	-61 Max	dB
26-Channel FLAT (5.0–200 MHz)	$XM_{26}$	-62 Typ	-61 Typ	dB

#### NOTES:

1. Response and return loss characteristics are tested and guaranteed for the full 5.0–200 MHz frequency range.
2. Motorola 100% distortion and noise figure testing is performed over the 5.0–175 MHz frequency range. Cross modulation and composite triple beat testing are with 22-channel loading; Video carriers used are:

T7–T13	7.0–43.0 MHz	7-Channels
2–6	55.25–83.25 MHz	5-Channels
A–7	121.25–175.25 MHz	10-Channels
3. Video carriers used for 12-Channel typical performances are T7–6; For 26-Channel typical performance, Channels 8, 9, 10 and 11 are added to the 22-Channel carriers listed above.

## The RF Line Low Distortion Wideband Reverse Amplifier Modules

Designed specifically for broadband applications requiring low distortion characteristics. Specified for use as return amplifiers for low-split 2-way cable TV systems. Features all gold metallization system.

- Guaranteed Broadband Power Gain
- Guaranteed Broadband Noise Figure
- Superior Gain, Return Loss and DC Current Stability with Temperature
- All Gold Metallization
- Circuit Design Optimized for Good RF Stability Under High VSWR Load Conditions
- Transformers Designed to Insure Good Low Frequency Gain Stability versus Temperature

## The RF Line 110-Channel (750 MHz) CATV Amplifier

The MHW7222A is designed specifically for up to 750 MHz CATV systems as amplifiers in trunk and line extender applications. This amplifier features ion-implanted, arsenic emitter transistors, an all gold metallization system and offers improved ruggedness and distortion performance.

- Specified for 110-Channel Performance
- Broadband Power Gain — @  $f = 40\text{--}750\text{ MHz}$   
 $G_p = 22.3\text{ dB Typ @ }750\text{ MHz}$
- Broadband Noise Figure

**MHW8222**

**The RF Line**  
**128-Channel (860 MHz)**  
**CATV Amplifier**

The MHW8222 is designed specifically for up to 860 MHz CATV systems as amplifiers in trunk and line extender applications. These amplifiers feature ion-implanted, arsenic emitter transistors and an all gold metallization system.

- Specified for 128-Channel Performance
- Broadband Power Gain — @ f = 40–860 MHz  
     $G_p = 22.3$  dB Typ @ 860 MHz
- Broadband Noise Figure  
    NF = 6.4 dB Typ
- Superior Gain, Return Loss and DC Current Stability with Temperature
- All Gold Metallization

# Chapter Eight

## Tape and Reel Specifications

---

Motorola offers the convenience of Tape and Reel packaging for our growing family of standard integrated circuit products. Reels are available to support the requirements of both first and second generation pick-and-place equipment. The packaging fully conforms to the latest EIA-481A specification. The antistatic embossed tape provides a secure cavity, sealed with a peel-back cover tape.

### Table of Contents

	<b>Page</b>
Tape and Reel Specifications . . . . .	8.1-2
Embossed Tape and Reel Ordering Information . .	8.1-4
Embossed Tape and Reel Data for Discretes . . . .	8.1-5

# RF and IF Tape and Reel Specifications

Embossed Tape and Reel is used to facilitate automatic pick and place equipment feed requirements. The tape is used as the shipping container for various products and requires a minimum of handling. The antistatic/conductive tape provides a secure cavity for the product when sealed with the “peel-back” cover tape.

- Two Reel Sizes Available (7” and 13”)
- Used for Automatic Pick and Place Feed Systems
- Minimizes Product Handling
- EIA 481, -1, -2
- SC-70/SOT-323, SC-70ML/SOT-363, SC-90/SC-75, SOT-23, SOT-24, SOT-143 in 8 mm Tape
- Micro-8, PLD-1, PLD-1.5, SO-8,  $\mu$ 200S,  $\mu$ 200Z in 12 mm Tape
- SO-14, SO-16/16L, LQFP24, LQFP-32, LQFP-48, TSSOP-16/16EP, TSSOP-20/20HS in 16 mm Tape
- QFP-52, SO-20L, SO-24L, SO-28L,  $\mu$ 250S in 24 mm Tape
- NI-600,  $\mu$ 400,  $\mu$ 400S in 32 mm Tape
- 465, 465A in 56 mm Tape

Use the standard device title and add the required suffix as listed in the option table on the following page. Note that the individual reels have a finite number of devices depending on the type of product contained in the tape. Also note the minimum lot size is one full reel for each line item, and orders are required to be in increments of the single reel quantity.

**TSSOP-16/16EP** (16 mm)

**TSSOP-20/20HS** (16 mm)

**μ250S** (24 mm)

**NI-600** (32 mm)

**μ400, μ400S** (32 mm)

**465, 465A** (56 mm)

56 mm	46.0 mm (1.811")				26.2 ± 0.15 mm (1.031 ± .006")	—		2.0 ± 0.15 mm (.079 ± .006")	100 mm (3.397")		56.3 mm (2.217")

Metric dimensions govern — English are in parentheses for reference only.

NOTE 1:  $A_0$ ,  $B_0$ , and  $K_0$  are determined by component size. The clearance between the components and the cavity must be within .05 mm min. to .50 mm max., the component cannot rotate more than 10° within the determined cavity.

NOTE 2: If  $B_1$  exceeds 4.2 mm (.165) for 8 mm embossed tape, the tape may not feed through all tape feeders.

NOTE 3: Pitch information is contained in the Embossed Tape and Reel Ordering Information on pg. 8.1–4.

# Chapter Ten

## Applications and Product Literature

---

Motorola's Applications Literature provides guidance to the effective use of its semiconductor families across a broad range of practical applications. Many different topics are discussed in a way that is not possible in a device data sheet, from detailed circuit designs complete with PCB layouts, through matters to consider when embarking on a design, to complete overviews of product families and their design philosophies.

Information is presented in the form of Application Notes, Article Reprints and detailed Engineering Bulletins.

### Table of Contents

	<b>Page</b>
Applications Literature .....	10.1–2
Product Literature .....	10.1–3

# Literature

Application Notes, Engineering Bulletins and Article Reprints of special interest to designers of RF and RF/IF equipment are listed below. This technical documentation is available on the Motorola Semiconductor Product Sector Web site or is available through the Motorola Literature Distribution Center. Phone and fax numbers for ordering literature are listed on the back cover of this book and in our Accessing Data On-line section.

## Application Notes

- |        |  |        |  |
|--------|--|--------|--|
| AN139A | Understanding Transistor Response Parameters                               | AN1030 | 1 W/2 W Broadband TV Amplifier Band IV and V   |
| AN211A | Field Effect Transistors in Theory and Practice                            | AN1032 | How Load VSWR Affects Non-Linear Circuits  |
| AN215A | RF Small-Signal Design Using Two-Port Parameters                           | AN1033 | Match Impedances in Microwave Amplifiers   |
| AN238  | Transistor Mixer Design Using 2-Port Parameters                            | AN1034 | Three Balun Designs for Push-Pull Amplifiers   |
| AN267  | Matching Network Designs with Computer Solutions                           | AN1037 | Solid-State Power Amplifier — 300 Watt FM, 88–108 MHz  |
| AN282A | Systemizing RF Power Amplifier Design                                      | AN1038 | 1.2 V, 40 – 900 MHz Broadband Amplifier with the TP3400 Transistor                                       |
| AN419  | UHF Amplifier Design Using Data Sheet Design Curves                        | AN1039 | 470 – 860 MHz — Broadband Amplifier – 5 W  |
| AN423  | Field Effect Transistor RF Amplifier Design Techniques                     | AN1040 | Mounting Considerations for Power Semiconductors   |
| AN535  | Phase-Locked-Loop Design Fundamentals                                      | AN1041 | Mounting Procedures for Very High Power RF Transistors   |
| AN548A | Microstrip Design Techniques for UHF Amplifiers                            | AN1107 | Understanding RF Data Sheet Parameters   |
| AN555  | Mounting Stripline-Opposed-Emitter (SOE) Transistors                       | AN1207 | The MC145170 in Basic HF and VHF Oscillators   |
| AN593  | Broadband Linear Power Amplifiers Using Push-Pull Transistors              | AN1253 | An Improved PLL Design Method Without $\omega_n$ and $\zeta$   |
| AN721  | Impedance Matching Networks Applied to RF Power Transistors                | AN1277 | Offset Reference PLLs for Fine Resolution or Fast Hopping  |
| AN749  | Broadband Transformers and Power Combining Techniques for RF               | AN1526 | RF Power Device Impedances: Practical Considerations   |
| AN758  | A Two-Stage 1 kW Solid-State Linear Amplifier                              | AN1528 | Packaging Considerations for RF Transistors  |
| AN762  | Linear Amplifiers for Mobile Operation                                     | AN1529 | RF Power Circuit Concepts Using FETs and BJTs  |
| AN779  | Low-Distortion 1.6 to 30 MHz SSB Driver Designs                            | AN1530 | Motorola Advanced Amplifier Concept Package  |
| AN790  | Thermal Rating of RF Power Transistors                                     | AN1531 | Parameter Extraction Techniques for RF Power Transistors Models  |
| AN791  | A Simplified Approach to VHF Power Amplifier Design                        | AN1539 | An IF Communication Circuit Tutorial   |
| AN827  | The Technique of Direct Programming by Using a Two-Modulus Prescaler       | AN1575 | Worldwide Cordless Telephone Frequencies   |
| AN860  | Power MOSFETs versus Bipolar Transistors                                   | AN1580 | Mounting and Soldering Recommendations for the Motorola Power Flat Pack Package                          |
| AN878  | VHF MOS Power Applications   | AN1599 | Power Control with the MRFIC0913 GaAs Integrated Power Amplifier and MC33169 Support IC                  |
| AN923  | 800 MHz Test Fixture Design  | AN1602 | 3.6 V and 4.8 V GSM/DCS1800 Dual Band PA Application with DECT Capability Using Standard Motorola RFIC's |
| AN955  | A Cost Effective VHF Amplifier for Land Mobile Radios                      | AN1610 | Using Motorola's MRFIC1502 in Global Positioning System Receivers  |
| AN1022 | Mechanical and Thermal Considerations in Using RF Linear Hybrid Amplifiers | AN1617 | Mounting Recommendations for Copper Tungsten Flanged Transistors   |
| AN1024 | RF Linear Hybrid Amplifiers  | AN1639 | Phase Noise Measurement Using the Phase Lock Technique   |
| AN1025 | Reliability Considerations in Design and Use of RF Integrated Circuits     | AN1643 | RF LDMOS Power Modules for GSM Base Station Application: Optimum Biasing Circuit                         |
| AN1026 | Extending the Range of an Intermodulation Distortion Test                  | AN1658 | Converting MC13110/13111 Based Designs to the MC13110A,B/13111A,B  |
| AN1027 | Reliability/Performance Aspects of CATV Amplifier Design                   | AN1670 | 60 Watts, GSM 900 MHz, LDMOS Two-Stage Amplifier   |
| AN1028 | 35/50 Watt Broadband (160 – 240 MHz) Push-Pull TV Amplifier Band III       |        |  |
| AN1029 | TV Transposers Band IV and $VP_O = 0.5 \text{ W}/1.0 \text{ W}$            |        |  |
